Anti-obesity and Anti-lipidemic Properties of Ascorbic Acid in Fructose Induced Obese Wistar Rats

Dr Temitope Deborah Fabiyi-Edebor

ABSTRACT

There are controversies as to whether ascorbic acid is efficacious in inducing weight loss and lowering lipid in obese subjects. Therefore, this study investigates the role of ascorbic acid in the treatment of obesity. Twenty-four male wistar rats were randomly divided into control, fructose, ascorbic acid and statin (n=6). Obesity was induced in the rats via free gavage drinking of fructose solution (20% w/v). Then, ascorbic acid group received 1g/kg/p.o ascorbic acid while statin group received 200mg/kg/p.o atorvastatin through oral canula for two weeks. The waist circumference, body weight, nose-anal length and Lee obesity index of the rats were measured using a vernier caliper, weighing balance and tape respectively. Serum Apolipoprotein A1 and B, Superoxide dismutase (SOD), malondialdehyde (MDA), glutathione (GSH) and ascorbic acid were determined spectrophotometrically. Analysis of variance (ANOVA) was used to analyze data at α=0.05. The significant (p<0.01) increases in waist circumference, body weight, nose-anal length, apolipoprotein B and a lee index >300 indicated that fructose induced obesity and dyslipidemia in the wistar rats. But ascorbic acid and statin decreased (p<0.05) the waist circumference, body weight, Lee index and apolipoprotein B in the obese rats. Also, serum MDA and SOD increased while glutathione and ascorbic acid decreased significantly (p<0.05) in the obese rats, however, these were reversed upon ascorbic acid and statin treatment. Thus, ascorbic acid may serve as an anti-obesity and anti-lipidemic agent via acting on oxidative stress pathway.

Keywords: Anti-oxidant, Ascorbic acid [vitamin C], Fructose, Obesity, Oxidative stress.

I. INTRODUCTION

Highlight Obesity is a clinical condition characterized by excess accumulated body fat detrimental to health. It is usually indicated by a body mass index [BMI] greater than 30 kg/m2 and waist-hip ratio greater than 0.85/0.95 in females/males. Obesity is a leading preventable cause of death globally with over 700 million adults and children having the condition as at 2015 amounting to about 12% of the world’s population [1], [2]. It is a condition of public health concern as it is associated with morbilities such as cardiovascular diseases, type 2 diabetes, obstructive sleep apnea, osteoarthritis, depression and cancer [3], [4]. Consumption of fructose sweetened drinks is a contributing factor to the rising rates of obesity as it increases de novo lipogenesis and triglyceride accumulation [in adipocytes] which in excess results in oxidative stress [5], [6]. In obesity, adipocytes secrete bioactive molecules such as adipokine, cytokines and reactive oxygen and nitrogen species [6], [7]. Thus, the increased production of reactive species coupled with reduced anti-oxidant factors result in oxidative stress. Oxidative stress has been suggested as the link between obesity and its associated complications [6], [7], however, it has also been implicated in the pathogenesis of obesity as per it has been shown that oxidative stress leads to weight gain [6]. Hence, the use of potential pharmacological and non-pharmacological interventions aimed at reducing oxidative stress in obese individuals in order to reverse the condition and/or prevent the development of obesity-related complications. Such interventions serve as alternative therapies to anti-obesity drugs which usually have psychiatric, gastrointestinal and cardiovascular side effects [8].

Anti-oxidants are gaining more recognition in the management of obesity. Ascorbic acid is an anti-oxidant that has been reported to possess free radical scavenging potential.9 Studies have shown that obese individuals have ascorbic acid deficiency which strongly correlated positively with abdominal obesity, body fat, waist circumference and waist-hip ratio [10]-[12]. Thus, ascorbic acid may be beneficial in the treatment of obesity. However, more experimental studies are required to establish the use of ascorbic acid in obesity treatment because controversy abounds as to whether ascorbic acid is efficacious or not in

inducing weight loss and lowering lipid in obese subjects [13]-[15]. Therefore, this study investigates the role of ascorbic acid in the treatment of obesity. The study hypothesizes that acute administration of ascorbic acid may reverse high calorie induced obesity by investigating the effects of ascorbic acid on parameters of obesity and lipidaemia in fructose induced obese wistar rats in comparison with statin.

II. MATERIALS AND METHODOLOGY

A. Animal Grouping

Twenty-four male Wistar rats weighting between 200-220g were used for this study. They were bred and housed in a standard animal house where they were well cared for and had free access to standard pellet and clean drinking water. The rats were divided into four groups namely control, fructose, ascorbic acid and statin with n=6. Obesity was induced in the rats by giving them twenty percent fructose solution via free gavage drinking for two weeks while the control group kept drinking clean water. After the fructose feeding period, ascorbic acid group was treated with 1 g/kg/p.o ascorbic acid (sigma) while the statin group received 200 mg/kg/p.o of statin [atorvastatin] through oral canula for two weeks.

B. Waist circumference and Lee index of obesity

The circumference of the rats was measured using a vernier caliper. Rats were restrained and the caliper was placed just before the hind limbs for this measurement.

C. Body weight

Rat bod weight was measured using a weighing balance while their nose-anal length (NAL) was measured using a standard measuring tape. The values of both weight and length were used to compute the lee index of obesity using the formula:

\[
\frac{\text{((g)^{1/3} x1000)}}{\text{NAL[cm]}}
\]

D. Lipid

Lipid profile was assessed by examining the apolipoprotein B and A1 content of blood serum of the rats. Apolipoprotein A1 and B concentrations in the sera were measured spectrophotometrically using immunoturbidimetric assay.

E. Oxidative stress

Superoxide dismutase (SOD), malondialdehyde (MDA), glutathione (GSH) and ascorbic acid were measured using spectrophotometry.

F. Statistical Analysis

Results are presented as mean ± S.E.M. and data was analyzed with ANOVA at P<0.05.

III. RESULTS

The significant increase in body weight (p<0.001, Fig. 1), nose-anal length (Table 1), waist circumference (p<0.01, Fig. 2), apolipoprotein B (p<0.05, Table 2) and a lee index greater than 300 [p<0.01, Fig. 3] indicated that fructose enriched drink induced obesity in the wistar rats. However, there was a significant decrease in the body weight (Fig. 1), waist circumference (Fig. 2) and Lee index (Fig. 3) of ascorbic acid and statin treated obese wistar rats, with the decrease in the ascorbic acid treated group more pronounced than in the statin treated group. Serum MDA and SOD increased whereas glutathione and ascorbic acid decreased significantly (p<0.05) in the obese rats. However, these were reversed upon ascorbic acid and statin treatment (Table 2). Apolipoprotein A1 was significantly (p<0.05) decreased in fructose obese rats while apolipoprotein B was decreased (p<0.05) in ascorbic acid and statin groups (Table 3).

TABLE 1: EFFECT OF ASCORBIC ACID AND STATIN ON THE NOSE-ANAL LENGTH OF FRUCTOSE INDUCED OBESE RATS

| Groups    | Pre-Fructose [cm] | Post-Fructose [cm] | Post-treatment [cm] |
|-----------|-------------------|--------------------|---------------------|
| control   | 22.6±1.0          | 23.2±2             | 23.7±1.8            |

IV. DISCUSSION

Obesity was induced in the rats after drinking twenty percent fructose solution, in addition to their normal chow diet, freely for two weeks. This is shown by the increased body weight, waist circumference and a ‘Lee index of obesity’ greater than 300 [16], [17]. A Lee obesity index greater than 300 is widely accepted as an indicator for the presence of obesity in rats [17], [18]. The Lee obesity index is the equivalent of BMI used to depict obesity in humans. It correlated positively with percentage body fat and weight for animals made obese by diet and is thus a simple and reliable predictor for percentage body fat and obesity in rodents [18].

In this study, obese rats treated with ascorbic acid showed marked weight loss and a reduction in Lee obesity index to a non-obese value similar to control and statin treated groups. This indicated that ascorbic acid was effective in reducing percentage body fat and waist fat in addition to causing weight loss. Diet induced obesity may be associated with oxidative stress [19]-[21] as shown in this study by the increased super oxide activities and malondialdehyde.
production from peroxidation of lipids. In addition, lipid peroxidation is an oxidative marker which correlates positively with lea obesity index and waist circumference [17]. Thus, ascorbic acid may exert its anti-obesity effects by acting on the oxidative stress pathway via eliminating reactive oxygen species such as super oxide, downregulating lipid peroxidation (MDA) and increasing endogenous glutathione antioxidant levels. Another possible mechanism by which ascorbic acid may induce weight loss in obesity may be by interfering with the leptin pathway as ascorbic acid has been reported to inhibit leptin secretion which may in turn alter eating habits to reduce food intake and promote the feeling of satiety [19], [20]. In this study, ascorbic acid ameliorated dyslipidemia in the obese rats by downregulating apolipoprotein B, a low-density lipoprotein (LDL) indicator, and upregulating apolipoprotein A1, a high-density lipoprotein (HDL) predictor. This effect was also observed in obese rats treated with statin a reductase inhibitor used in lowering LDL cholesterol. Statin has been shown to have antioxidant properties in addition to its anti-oxididemic effect, however, ascorbic acid is a more potent anti-oxidant. Increased apolipoprotein B and decreased apolipoprotein A are reliable indicators of the presence of dyslipidemia. Dyslipidemia is a complication of obesity that has been linked, to a large extent, to increased oxidative stress [21]. Thus, ascorbic acid may ameliorate dyslipidemia by interfering with the oxidative stress pathway involved in its pathogenesis.

V. CONCLUSION

Ascorbic acid may serve as an adjunct therapy in the treatment of obesity and dyslipidemia via acting on oxidative stress pathway to decrease the production of reactive molecules and increase endogenous anti-oxidant statin.
