An Assessment of Seaweeds Diversity and Distribution at the Beach of Nathia Gali, Karachi, Pakistan

*Rashida Qari
Institute of Marine Sciences, University of Karachi, Karachi, Pakistan

Abstract
The seaweed resources were sampled from exposed shore of Nathia Gali beach, Karachi coast at low tide. The present data of diversity and biomass of seaweeds provide a comparison of two different periods i.e., from 1989 to 1991 and 2012. A total of 60 taxa were recorded in the coastal area of Nathia Gali; 14 belonging to chlorophyta, 15 to Phaeophyta and 31 to Rhodophyta. The green seaweeds viz., Caulerpa racemosa, Codium iyengarii and Halimeda tuna; brown seaweeds, Cystoseira indica, Iyengaria stellata Padina pavorica and Sargassum boveanum and red seaweeds Gracilaria corticata and Scinaia fascicularis were found to be the dominant species of Nathia Gali. The total biomass 66056.18 g m\(^{-2}\) was recorded during the study period and the highest biomass was recorded in January (16551.79 g m\(^{-2}\)) and the lowest in July (1276.3 g m\(^{-2}\)). In winters, seaweeds biomass and growth increased due to low temperature of air and seawater with low intensity of light and high dissolved nutrients. The richness of seaweed resources in the studied area is due to the intertidal rocks available on the coast but nowadays, there is lot of disturbance due to anthropogenic activities such as discharge of domestic and industrial waste; tanneries effluents; rainfall and associated pollutant from runoff; shipping and agricultural sources. These disturbances play vital role in changing the ecosystem which effects flora and fauna of the coast.

Keywords: Diversity; Distribution; Seaweeds; Nathia Gali; Biomass; Community

Introduction
The floral components are represented by three groups of primary producers, the mangroves, sea grasses and the seaweed [1]. The macrobenthic algae are an important component of the marine ecosystem. They exhibit an enormous variety in size, color, form, and lifestyle and they are extremely rich in the sea. According to a very rough estimate there are more than 17,000 species of sea plants and 95% of them are algae [2]. To date, several investigations for the exploitation of seaweed resources in developed countries have been made about biomass and standing crop. More recently Faveri et al. [3] studied the temporal changes in the seaweeds flora in Southern Brazil and its potential causes. Hay and Villout [4] studied the seasonality of Undaria pinnatifida population in New Zealand waters. Jagtap [5] described the marine flora of Nicobar group of islands in Andaman Sea. Ballesteros [6] studied seasonal growth and production of deep-water population of Halimeda tuna in the Northwestern Mediterranean. Pedrini et al. [7] reported the marine algae of Trindade Island, Brazil. Basson et al. [8] also reported the benthic flora of Bahrain. Chock and Mathieson [9] quantified the standing crop and biomass variation of estuarine seaweed at Cedar point, Dover New Hampshire Maine, UK. Similar studies have also been conducted in other areas of the world such as, North Carolina [10], India [11], Dodger channel of Canada [12] and Central Puget Sound Washington, U.S.A. [13]. Josselyn and Mathieson [14] have reported the biomass variation of selected estuarine macrophytes at North temperate estuary, Falmouth Massachusetts, USA.

The seaweed resources are abundant around the rocky shores of Karachi. Many studies have been made on the standing crop and biomass of seaweeds like Shamel [15] served seaweed of from the coast of Lasbella, Pakistan. Saleem [16] and Saifullah [17] studied the distribution and biomass of marine algae along Karachi. Qari and Qasim [18,19] investigated the seasonal change in the standing crop of intertidal seaweeds from the Buleji and Manora coast of Karachi. Recently Qari et al. [20] studied Phymatom on natural bed of seaweet at Paradise Point, Karachi coast.

Pakistan is a developing country; the marine resources like seaweeds are under threat due to variety of pollutants. There are above 6,000 industries located in Karachi at different sites. According to an estimate all these industries contribute approximately 99% of the total industrial pollution beside the contamination from oil waste discharge [21,22]. Increasing concern on wrecking of floral resources deemed it necessary to study the seaweeds diversity and abundance for a better management of marine flora. At Nathia Gali of Karachi coast no any information on diversity of seaweeds although this coast has very luxuriant seaweed vegetation, therefore the present investigation deals with the seaweeds biomass, distribution, diversity of seaweeds species (Chlorophyta, Phaeophyta and Rhodophyta) of Nathia Gali coast Karachi, northern Arabian Sea.

Materials and Methods
The investigation was carried out at Nathia Gali that presents a very scenic point also known as Pacha, is situated at 24°50’ N, 66° 42.5’ E on the south western coast of Arabian Sea. It is not easily assessable; as a result it is still consist of undisturbed forms of flora and fauna. The jutting rocks lessen the force of the waves thus protecting the backwater beach and along with it the existing life. The beach starts with pale yellow coloured rocks at its front, the main boulder like forms, is exposed to the surface and slopes steep towards the sea. The sides of these rock formations are thickly covered with the biota especially rich in seaweed.

When the tide is low the back area is fully exposed while at high tides even the facing rock zone gets submerged with seawater.

Field surveys were undertaken to the selected sampling beach (Nathia Gali) of the Karachi coast over a period of four years from 1989 to 1991 and 2012 for the comparison of two data of different period. The seasonal distribution of seaweeds was studied by a wooden quadrat frame of one-meter square [23]. Each month fifty quadrates (ten feet apart) from low tidal mark to high tidal mark were randomly sampled in the intertidal belt. Phytomass falling inside each quadrat were harvested and studied for the composition and biomass. All seaweeds placed individually in prelabeled plastic bags and returned to the laboratory.

All collected seaweeds samples were carefully cleaned from mud debris and epiphytes, using seawater. For identification, the materials were sorted out on the basis of Anand [24,25], Round [26], Chapman and Chapman [27], Dawes [28], Morris [29], Dring [30]. The total and the differential biomass (wt. weight) of each species was estimated after carefully scraping them and weighed with a fine degree of accuracy (0.001 g) and subsequently the biomass of each species was calculated and expressed in gram fresh weight per square meter (g. m⁻²). The average values of fifty quadrates were pooled and are used for comparing the condition in different seasons. The Shannon – Weiner diversity index of each monthly sample was calculated by using the formula on Excel program. Species richness and species evenness also calculated.

\[
\text{Diversity } H' = - \sum pi \ln pi \\
\text{Species richness } S' = S / \sqrt{N} \\
\text{Evenness } J = H' / H \text{ max}
\]

### Results and Discussion

The rocky beach of Nathia Gali is very rich in seaweed. A total of sixty species of seaweeds (Fourteen green, fifteen brown and thirty-one red) were identified over the period of four years (January 1989 to December 1991 and 2012) (Tables 1-3). The total biomass 66056.18 g. m⁻² was recorded during the study period and the highest biomass was recorded in January (16551.79 g. m⁻²) and the lowest (1276.3 g. m⁻²) was recorded in July (Figure 1). Figure 2 showed the highest contribution to the total biomass was observed by green seaweed 66.43 % followed by brown (17.85 %) and red (15.72 %). The highest total biomass value was recorded in the year 1991 (26921.1 g. m⁻²) as compared to the values of other years of study period i.e., (1989: 16108.12 g. m⁻², 1990: 6129.18 g. m⁻² and 2012: 16897.78 g. m⁻²) (Figure 3). The highest contribution of green seaweed was found in January (12929.67 g. m⁻²) whereas the lowest in July (566.73 g. m⁻²) (Figure 1). Green seaweeds were more abundant in the year 1989 (13822.96 g. m⁻²) than the other three years 1990 (3587.64 g. m⁻²), 1991 (14331.01 g. m⁻²) and 2012 (12139.96 g. m⁻²) (Table 1 and Figure 2). The highest contribution of brown seaweed occurred in January (2360.66g. m⁻²) whereas the lowest in August from Nathia Gali (195.79 g. m⁻²) (Figure 1). The maximum biomass of brown year 1991 (Table 2 and Figure 2). The highest seaweed (4940.69 g. m⁻²) was observed in the contribution of total biomass of red seaweed occurred in February (3306.81 g. m⁻²) and the lowest contribution of total biomass of red seaweed was collected in August (96.38 g. m⁻²) (Figure 1). The maximum biomass of red seaweed (7649.4 m⁻²) was observed in the year 1991 (Table 3 and Figure 2). Seasonal variations in number of seaweed species collected at Nathia Gali of Karachi coast is given in Table 4. During the whole study period, all studied sixty seaweed species were collected 746 times. The highest number of seaweed species was recorded in March (101) and the lowest number of species (27) was recorded in August (Table 4). The highest contribution to the total number of seaweed species were by red seaweed (42.49 %) in comparison to brown (32.71 %) and green (24.8 %) seaweed. This indicates that red seaweed showed greater species diversity at Nathia Gali coast. There was positive significant correlation was found in between total biomass of green and brown seaweeds (r²=0.852), green and red seaweeds (r²=0.568) and brown and red seaweeds (r²=0.751) (Figures 4-6). The completely randomized design with nested treatments analysis of variance (ANOVA) model was used to test the significant differences of biomass in seaweed between years and months. The results show that there were high significant variations were observed between years and months (F=12.52 and F=4.42 for years and months, respectively) in the total biomass of seaweeds. Significant variations were also observed between years and months in total biomass of green seaweed (F=3.71 and F=5.69 for years and months, respectively) and brown seaweeds (F=6.77 and F=4.32 for years and months, respectively) but significant variations were observed only in between years for the total biomass of red seaweed (F=6.06) (Table 5).

Seaweeds found in the present study were categorized into four groups based on their frequency of occurrence during the study period [31]. Species found mostly all year round i.e., nine to twelve months named as perennials and species found in the major portion of the year i.e., from six to eight months called pseudoperennials. Annual seasons were those species found in limited period of occurrence i.e., from three to five month and species restricted to only one, two or three months named as rare.

The detail account of biomass for each species is given below alphabetically as presented in Tables 1-3 for each group of seaweeds.

### Chlorophyceae (green seaweed)

*Bryopsis harveyana* was rare and was found in different months. The total biomass of this seaweed ranged from 0.82-5.41 g. m⁻². *Caulerpa manaccensis* was also rare and was found only in November 1990 (0.33 g. m⁻²) and September (0.65 g. m⁻²) and October 2012 (0.76 g. m⁻²). *C. peltata* species was also rarely collected and the biomass ranged from 11.65-40 g. m⁻². *C. racemosa* species classified as pseudoperennial and the maximum biomass were recorded in January (225.2 g. m⁻²) and February (224.32 g. m⁻²) of 1990 and minimum value of biomass was recorded in May (0.85 g. m⁻²) 1989. *C. scalpelliformis* species was seasonal annual (1.37-74.43 g. m⁻²). *C. taxifolia* was rare with biomass 0.53 g. m⁻² in November of 1990 and April (0.44 g. m⁻²) and May (0.45 g. m⁻²) of 2012. *Codium iyengarii* species was pseudoperennial, found abundantly compared to all other green species. The maximum values were recorded in the month of January (5511.4 g. m⁻²) and minimum value was recorded in October (44.96 g. m⁻²). *C. shamelii* (16.07-425 g. m⁻²) and *Entomerompha compressa* species (16-432 g. m⁻²) were also rare. *Halimeda tuna* species was seasonal annual in 1989 and 1990 but in 1991 and 2012 this species was pseudoperennial. A maximum biomass value was observed in February 2012 (44.6 g. m⁻²) whereas minimum value was recorded in February 1989 (1.5 g. m⁻²). *Udotea indica* was rare and found only in low quantity (1.17-9.22 g. m⁻²). *Ulva fasciata* was seasonal annual and the biomass ranged from 0.35-360.2 g. m⁻². *U. lactuca* and *Valoniopsis pachynema* were also rare and found with very low range in a whole study period (1.42-22.14 g. m⁻² and 0.1-420 g. m⁻² respectively) (Table 1).

### Phaeophyceae (brown seaweed)

*Colpomenia sinuosa* species was seasonal annuals (4.79-171 g. m⁻²)

Citation: Qari R (2017) An Assessment of Seaweeds Diversity and Distribution at the Beach of Nathia Gali, Karachi, Pakistan. J Marine Sci Res Dev 7: 228. doi: 10.4172/2155-9910.1000228
and abundantly found during December to January. Cystoseira indica species was seasonal annual (0.25-58.58 g. m\(^{-2}\)). Dictyopteris dichotoma species was seasonal annual (7.3-72.43 g. m\(^{-2}\)) whereas the other species of the same genus D. hauckiana was rare collected only in 1991 in the month of November (16 g. m\(^{-2}\)) and in 2012 in the months of January (3 g. m\(^{-2}\)) and February (7.2 g. m\(^{-2}\)). Iyengaria stellata species was pseudoperennial in 1991 and seasonal annual in other three years (1989, 1990 and 2012). The highest biomass was collected in December 1991 (425 g. m\(^{-2}\)) and lowest was recorded in March 1990 (12.36 g. m\(^{-2}\)). Jolyna laminarioides (16-25.11 g. m\(^{-2}\)) was also rare. Among Phaeophyceae (brown seaweed) Padina pavonica was perennial and was collected all year round except in the year of 1990 it was seasonal annual. Highest peak of abundance was found in April 1989 (55.3 g. m\(^{-2}\)) and lowest biomass was recorded in December 1991 (0.35 g. m\(^{-2}\)). P. tetrastridomaica species was rare (0.8-17.33 g. m\(^{-2}\)). Sargassum boveanum species was Pseudoperennial. The biomass was high in June 1989 (242.34 g. m\(^{-2}\)), July 1990 (110 g/m\(^2\)), and January 1991 (344 g. m\(^{-2}\)) and in April 2012 (256 g. m\(^{-2}\)). S. lanceolatum species was rare in 1989 and 1990, pseudoperennial in 1991 and perennial in 2012. The maximum value was obtained in June 1990 (47.93 g. m\(^{-2}\)) and minimum was recorded in September 1989 (4.8 g. m\(^{-2}\)). S. tenerimum was rare (4-153.6 g. m\(^{-2}\)) in the whole study period whereas S. wightii species was not present in 1989 and rare in 1990 and in 1991 and 2012 it was pseudoperennial. Its maximum value was obtained in January 1991(104.5 g. m\(^{-2}\)) and minimum was recorded in October 1990 (6.3 g. m\(^{-2}\)) 2012 (6 g. m\(^{-2}\)). Spatoglossum variabile was rare (2.45-16.44 g. m\(^{-2}\)) and Stoechospermum marginatum (1.5-160 g. m\(^{-2}\)) was seasonal annual (Table 2).

**Rhodophyceae (red seaweed)**

Botryocladia leptopoda species was found as seasonal annual (1.4 -120.5 g. m\(^{-2}\)). Calliblepharis fimbriata (0.6-0.45 g. m\(^{-2}\)) and all Champa species were found as rare i.e., Champa compressa (0.92-26.9 g. m\(^{-2}\)), C. plumose (3.8-9.17 g. m\(^{-2}\)) and C. salicornioides (10.3-13.6 g. m\(^{-2}\)). Coelarthurimum muelleri was seasonal annual (26.75-154 g. m\(^{-2}\)) in 1991 and in 1989 and 2012 it was rare whereas in 1990 it was not collected. Cystocolonium purpureum (2.5-28.78 g. m\(^{-2}\)), Gildium pusillum (2.5-18.5 g. m\(^{-2}\)) and G. usamanghani (0.23-11.25 g. m\(^{-2}\)) species were found rare. Gracilaria corticata was seasonal annual in 1989, 1990 and 2012 whereas in 1991 it was Pseudoperennial. The highest biomass was recorded in April 1991 (57 g. m\(^{-2}\)) and lowest biomass was recorded in March 1990 (3.51 g. m\(^{-2}\)). G. foliifera species was present only in 1991 (7.84-60 g. m\(^{-2}\)) and October 2012 (3.5 g. m\(^{-2}\)). G. pyrgoarea species was rare in 1989 (8.33 g. m\(^{-2}\)) and 1990 (6.6 g. m\(^{-2}\)), Pseudoperennial in 1991 (5.86-48.42 g. m\(^{-2}\)) and seasonal annual in 2012 (3.8-12.6 g. m\(^{-2}\)). G. verrucosa species was present only in 1991 as seasonal annual (19.24-65.2 g. m\(^{-2}\)). Halymeria porphyraeformis species was seasonal annual (1.2-100.2 g. m\(^{-2}\)). Hymenea muscosiforis was rare in 1989 (8 g. m\(^{-2}\)) and 1990 (2.1-17.95 g. m\(^{-2}\)), pseudoperennial in 1991 (0.78-290 g. m\(^{-2}\)) and seasonal annual in 2012 (1.6-13 g. m\(^{-2}\)). H. pannosa was seasonal annual (7.7-195 g. m\(^{-2}\)). H. valentea species was also seasonal annual in 1991 (13.72-205 g. m\(^{-2}\)) and 2012 (3-55 g. m\(^{-2}\)) whereas in 1989 and 1990 it was rare. Jania adhaerens (0.14-8.55 g. m\(^{-2}\)) and Laurencia obtuse (0.6-38 g. m\(^{-2}\)) were seasonal annual. Meynalia thomassii (90.47 g. m\(^{-2}\)), Osmundea pinnatifida (1.81-6.68 g. m\(^{-2}\)), Plocamium cartilagineum (0.62-30.21 g. m\(^{-2}\)) and Polysiphonia nizamuddinii (5.4-30.6 g. m\(^{-2}\)) were rare. Sarcothamnium dichotoma was rare in 1990 (8.5 g. m\(^{-2}\)) and 1991 (7.37-16.5 g. m\(^{-2}\)), pseudoperennial in 2012 (3-63.2 g. m\(^{-2}\)) and in 1990 it was absent. Sarcocornea filiforme was seasonal annual found only in 1991 (3.83-23.77 g. m\(^{-2}\)) and 2012 (2-12.5 g. m\(^{-2}\)). Scinaia fascicularis species was seasonal annual in 1989 (1.72-8.5 g. m\(^{-2}\)) and 1990 (0.24-46.35 g. m\(^{-2}\)), pseudoperennial in 1991 (22.6-132.21 g. m\(^{-2}\)) and perennial in

Figure 1: Seasonal variation in total biomass of seaweeds found at Nathia Gali beach.

Figure 2: Seasonal variation in total biomass of green, brown and red seaweeds at Nathia Gali beach.
2012 (2.5-63 g. m\(^{-2}\)). The highest biomass was recorded in March 1991 (132.21 g. m\(^{-2}\)) and lowest biomass was recorded in July 1990 (0.24 g. m\(^{-2}\)). \(S. hatei\) was rare found only in 1990 (64.5-74.94 g. m\(^{-2}\)), 1991 (111.14 g. m\(^{-2}\)) and 2012 (7-33.8 g. m\(^{-2}\)). \(S. saifullahii\) (7.2-320 g. m\(^{-2}\)), \textit{Sebdenia flabellate} (5.42-119 g. m\(^{-2}\)), \textit{Solieria robusta} (2.43-38.4 g. m\(^{-2}\)) and \textit{Trichleocarpa fragilis} (1.1-280 g. m\(^{-2}\)) species were rare (Table 3).

The total biodiversity index of seaweeds at Nathia Gali beach was -11.3641 ranged from -0.01083 to -1.10039. Figure 7 showed the monthly variation in Shannon-Weiner diversity index (\(H'\)) at Nathia...
Gali during the study period January 1989-December 1991 and 2012. The peak value was found in the month of March (-0.01083) while the lowest value was recorded in the month of September (-1.10039). The values of species richness S' varied from 0.298 to 0.577. The highest value (0.577) was observed in the month of August and lowest value (0.298) was recorded in March (Figure 8). The values of species evenness (J) ranged from -0.272 to -0.447. The maximum values of species evenness were observed in the months of August (-0.447) and minimum values in the month of June (-0.266) (Figure 9). The diversity, distribution and abundance of biomass varied from season to season and interannual variation were also observed in three years sampling consecutive like another coast of Karachi, Paradise Point [20]. The green seaweeds were the major contributors in biomass of intertidal seaweed whereas red seaweeds have greater diversity at the coast, showed maximum number of species. Aliya and Shameel [32] also observed the abundance of green seaweed and they occupy a large area of the Karachi coast with variation in the distribution of type and species. The green seaweed Caulerpa racemosa, Codium iyengarii and Halimeda tuna, brown seaweed, Cystoseira indica, Iyengaria stellata Padina pavonica and Sargassum boveanum, red seaweed Gracilaria corticata and Scinnaia fasicularis were found to be the dominant species of Nathia Gali in winter (December to January). This period is dominated with northeast monsoon wind season in the winter over the North Arabian Sea [33]. The richness of seaweed resources is due to the intertidal rocks available on the coast of Nathia Gali. In winter period due to low temperature of air and seawater with low intensity and small duration and high dissolve nutrients seaweeds biomass and growth increased when compared to other seasons [21,24]. Chauhan [34] has also found abundant growth of seaweed in winter. The lowest value of biomass was recorded in May to August and this period is associated with the southwest monsoon season. In this period most of the seaweeds were either absent from the rocky shores or an occasional species corresponding to low biomass were present because in this season sea becomes turbulent under the influence of strong winds and wave action and especially at the continental shelf likely inhibits the growth of drifted seaweed. Chock and Mathieson [9] from New England and Gaur et al. [11] from India found maximum values in October. Saifullah [17], Qari and Qasim [18,19] and Qari et al. [20] have observed the paucity of sublittoral seaweeds during May to August period. Satheesh and Wesley [35] reported the high seaweed abundance during pre-monsoon and low in post monsoon season at Kudankulam coastal waters, South-Eastern coast of India.

Seaweeds are important raw material in polysaccharides production. Most of them have very important economic value [36]. Michalak et al. [37] and Zia et al. [38-40] found that seaweeds could help to reduce the use of chemical fertilizer and improve physicochemical properties of the soil and to increase the plant growth. Gavino and Trono [38] reported that the seaweeds and their products are the third most important fishery export. From the present study, it is apparent that many economically and medicinally important species of seaweeds such as Gracilaria corticata, Hypnea musciformis, H. pannosa, Sargassum boveanum, Ulva fasciata etc., are richly found at this coast [37-40] but nowadays there is lot of disturbance due to anthropogenic activities such as discharge of untreated and partially treated domestic and industrial waste, coolant waters of industrial and atomic nuclear power plants and harbour activities such as dredging and cargo handling, the dumping of ship waste and other coastal activities. Therefore for the conservation of these resources it is need to control these pollutants and prohibited or ban on like these activities. The present comparative study of two different periods will be useful as new base line record for future floral studies on Nathia Gali coast.

Acknowledgement

Thanks and great regards to Prof. Dr. M. Shameel (Late) for help in identifying the species of seaweeds.
