Abstract

Conventional information systems cannot cater for temporal information effectively. For this reason, it is useful to capture and maintain the temporal knowledge (especially the relative knowledge) associated to each action in an information system. In this paper, we propose a model to mine and organize temporal relations embedded in Chinese sentences. Three kinds of event expressions are accounted for, i.e., single event, multiple events and declared event(s). Experiments are conducted to evaluate the mining algorithm using a set of news reports and the results are significant. Error analysis has also been performed opening up new doors for future research.

1 Introduction

Information Extraction (IE) is an upcoming challenging research area to cope with the increasing volume of unwieldy distributed information resources, such as information over WWW. Among them, temporal information is regarded as an equally, if not more, important piece of information in domains where the task of extracting and tracking information over time occurs frequently, such as planning, scheduling and question-answering. It may be as simple as an explicit or direct expression in a written language, such as “the company closed down in May, 1997”; or it may be left implicit, to be recovered by readers from the surrounding texts. For example, one may know the fact that “the company has closed down before the earthquake”, yet without knowing the exact time of the bankruptcy. Relative temporal knowledge such as this where the precise time is unavailable is typically determined by human. An information system which does not account for this properly is thus rather restrictive.

It is hard to separate temporal information (in particular refers to temporal relations in this paper) discovery from natural language processing. In English, tenses and aspects reflected by different verb forms are important elements in a sentence for expressing temporal reference (Steelman, 97) and for transforming situations into temporal logic operators (Bruce, 72). The pioneer work of Reichenbach (Reichenbach, 47) on tenses forms the basis of many subsequent research efforts in temporal natural language processing, e.g. the work of Prior in tense logic (Prior, 67), and of Hwang et al in tense tree (Hwang 92) and temporal adverbiaal analysis (Hwang 94), etc. Reichenbach argued that the tense system provided predication over three underlying times, namely $S$ (speech time), $R$ (reference time), and $E$ (event time). Later, a multiple temporal references model was introduced by Bruce (Bruce, 72). He defined the set $(S_1, S_2, ..., S_n)$, which is an element of a tense. $S_i$ corresponds to the time of speech. Each $S_i$ ($i = 2, ..., n - 1$) is a time of reference, and $S_n$, the time of an event. To facilitate logic manipulation, Bruce proposed seven first order logic relations based on time intervals and a method to map nine English tenses into temporal first order logic expressions\(^1\). His work laid down the foundation of temporal logic in natural language. These relations were then gradually expanded to nine in (Allen, 81) and further to thirteen in (Allen, 83)\(^2\).

In contrast, Chinese verbs appear in only one

\(^1\)The seven relations are symbolized as $R(A, B)$ for relation $R$ and time intervals $A$ and $B$, where $R$ includes before, after, during, contains, same-time, overlaps or overlapped-by.

\(^2\)meet, met-by, starts, started-by, finishes and finished-by are added into temporal relations.
form. The lack of regular morphological tense markers renders Chinese temporal expressions complicated. For quite a long time, linguists argued whether tenses existed in Chinese; and if they did how are they expressed. We believe that Chinese do have tenses. But they are determined with the assistance of temporal adverbs and aspect auxiliary words. For example, 在 ... 呢 (being), 已经 ... 了 (was/been) and 要 ... (will be) express an ongoing action, a situation started or finished in the past, and a situation which will occur in the future, respectively. Therefore, the conventional theory to determine temporal information based on verb affixations is inapplicable. Over the past years, there has been considerable progress in the areas of information extraction and temporal logic in English (Antony, 87; Bruce, 72; Kaufmann, 97). Nevertheless, only a few researchers have investigated these areas in Chinese.

The objective of our research is to design and develop a temporal information extraction system. For practical and cultural reason, the application target is on-line financial news in Chinese. The final system, referred to as TICS (Temporal Information-extraction from Chinese Sources), will accept a series of Chinese financial texts as input, analyze each sentence one by one to extract the desirable temporal information, represent each piece of information in a concept frame, link all frames together in chronological order based on inter- or intra-event relations, and finally apply this linked knowledge to fulfill users’ queries.

In this paper, we introduce a fundamental model of TICS, which is designed to mine and organize temporal relations embedded in Chinese sentences. Three kinds of event expressions are accounted for, i.e. single event, multiple events and declared event(s). This work involved four major parts, (1) built temporal model; (2) constructed rules sets; (3) developed the algorithm; and (4) set up the experiments and performed the evaluation.

2 A Model for Temporal Relation Discovery

2.1 Temporal Concept Frame

In IE, it is impossible as well as impractical to extract all the information from an incoming document. For this reason, all IE systems are geared for specific application domains. The domain is determined by a pre-specified concept dictionary. Then a certain concept is triggered by several lexical items and activated in the specific linguistic contexts. Each concept definition contains a set of slots for the extracted information. In addition, it contains a set of enabling conditions which are constraints that must be satisfied in order for the concept to be activated. Due to its versatility, a frame structure is generally used to represent concepts (as shown in Figure 1).

Slots in a temporal concept frame are divided into two types: activity-related and time-related. Activity-related slots provide the descriptions of objects and actions concerning the concept. For example, company, predator, company target and purchase value are the attributes of the concept (收购, TAKEOVER). Meanwhile, time-related slots provide information related to when a concept begins or finishes, how long does it last and how does it relate to another concept, etc.

![Temporal concept frame construction](image)

**Figure 1:** Temporal concept frame construction

2.2 Temporal Relations

The system is designed with two sets of temporal relations, namely absolute and relative relations. The role of absolute temporal relations is to position situation occurrences on a time axis. These relations depict the beginning and/or ending time bounds of an occurrence or its relevance to reference times, see TR(T) in Section 2.3. Absolute relations are organized by TimeLine in the system, see Figure 2.

![TimeLine organization for absolute relations in TICS](image)

**Figure 2:** The TimeLine organization for absolute relations in TICS

In many cases, the time when an event takes place may not be known. But its relevance to
another occurrence time is given. Relative temporal knowledge such as this is manifested by relative relations. Allen has proposed thirteen relations. The same is adopted in our system, see $TR(E_i, E_j)$ in Section 2.3. The relative relations are derived either directly from a sentence describing two situations, or indirectly from the absolute relations of two individual situations. They are organized by Relational_Chairs, as shown in Figure 3.

![Diagram of Temporal Relations](Image)

**Figure 3: The Relational_Chain organization for relative relations in TICS**

### 2.3 Temporal Model

This section describes our temporal model for discovering relations from Chinese sentences. Suppose $TR$ indicates a temporal relation, $E$ indicates an event and $T$ indicates time. The absolute and relative relations are symbolized as: $OCCUR(E_i, TR(T))$ and $TR(E_i, E_j)$, respectively. The sets of $TR$ are:

- $TR(T) = \{ON, BEGIN, END, PAST, FUTURE, ONGOING, CONTINUED\}$
- $TR(E_i, E_j) = \{BEFORE, AFTER, MEETS, MEETBY, OVERLAPS, OVERLAPPED, DURING, CONTAINS, STAREDBY, STARTS, FINISHES, FINISHEDBY, SAMEAS\}$

For an absolute relation of a single event, $T$ is an indispensable parameter, which includes event time $t_e$, reference time $t_r$ and speech time $t_s$.

$$ T = \{t_e, t_r, t_s\} $$

Some Chinese words can function as the temporal indicators. These include time word ($TW$), time position word ($P$), temporal adverb ($ADV$), auxiliary word ($AUX$), preposition word ($P$), auxiliary verb ($VA$), trend verb ($VC$) and some special verbs ($VV$). They are all regarded as the elements of the temporal indicator $TI$:

$$ TI = \{TW, F, ADV, AUX, VA, VC, VV, P\} $$

Each type of the indicators, e.g. $TW$, contains a set of words, such as $TW = twlist = \{tw_1, tw_2, ... tw_n\}$, with each word having a temporal attribute, indicated by $ATT$.

The core of the model is thus a rule set $R$ which maps the combinational effects of all the indicators, $TI$, in a sentence to its corresponding temporal relation, $TR$.

$$ R: TI \rightarrow \{ TR(T), TR(E_i, E_j) \} $$

Regarding to the temporal relations, the language has three basic forms in representation:

- Single event statement: in which only one single event is stated.
- Multiple events statement: in which two or more events are stated.
- declaration statement: in which the event(s) are declared by a person or an organization.

### 3 Rule Construction

#### 3.1 General Rules for Temporal References (GR)

Some general temporal characteristics, approximations and assumptions are examined to understand and uncover the hidden reference times, or to polish the identified solutions in order to make them more nature. For example, $PAST(\text{过去日期}, \text{reporting date})$ is probably better than $ON(\text{往前, a few days ago})$. Or, when no explicit reference time is given, the default value of $T$, i.e. the "reporting date" (thereafter referred to as RD), would be assumed. It must be noting that the rules given below are not for the immediate use of extracting $TR$. But they are necessary to design the TICS program.

1. **$TR(T)$ (single event) supports the following rules:**

   (1) Approximation:
   
   $$ ON(t_e) \oplus (ATT(T) = \text{"present"}) \Rightarrow ON(RD) $$
   $$ ON(t_e) \oplus (ATT(T) = \text{"past"}) \Rightarrow \text{PAST(RD)} $$
   $$ ON(t_e) \oplus (ATT(T) = \text{"future"}) \Rightarrow \text{FUTURE(RD)} $$
The combined effect of all the temporal indicators in a sentence determines its temporal relation. However, in different situations, a certain indicator may have different effects. Compared (a) 今天早上他看了报纸 (This morning, he read the newspaper) and (b) 昨天我读了两本书 (I read two books yesterday), the two sentences are alike as they both embody an indicator 了, which implies PAST in principle. The sole difference is that a definite time present in (b) means the reading is finished at the speech time and the person must have known some news or information from his reading. Thus TR = PAST(t_s) for (a). However, (b) means the event took place yesterday but not before yesterday. Consequently, for TR = ON(yesterday) is appropriate. In the database, the impact coefficients are defined for the temporal indicators when T does or does not present in the sentence.

**Remark:**

It is likely for a sentence to contain two or more indicators. For example, adverbs already and aspectual auxiliary word 了 together express a past tense and they both share the same reference time t_s. The same kind instances include 将要 (will) and 正在着 (being) etc. Another example, such as 国庆 前已经 (before the National Day, one has already), however includes two reference times. Here, 国庆 (National Day) is t_r, location word 前 (before) indicates PAST between t_s and t_r (i.e. t_r < t_s), and adverb 了 indicates the same relativity but between t_e and t_e (i.e. t_e < t_e).

\[
\begin{array}{ccc}
\text{国庆前} & \text{国庆} \\
{\text{t}_e} & {\text{t}_r} \\
\end{array}
\]

The current proposed algorithm is unable to mine the implicit reference time (i.e. t_e). But this does not affect the work at all. It does not matter even we cannot discover a relation like PAST(t_s). As we know t_s < t_r, we can deduce a conclusion such as t_r < t_s by rule PAST(t_r) \| PAST(t_s) \Rightarrow PAST(t_s) (for t_e). Thus, for this example, a relation of PAST(国庆, National Day) is enough to provide sufficient information to the users. To cater for these cases, we define a general rule: if all the indicators in a sentence indicate the same relation, then it is identified as TR (hereafter this rule together with impact coefficients is referred as R0).

### 3.3 Rules for Resolving Conflicts (R1)

In many situations, the indicators in a sentence may introduce more than one relation. For example, adverbs 已经 (have already) and in (being) indicate PAST and ONGING, respectively. But they could be collocated to represent some event which began in the past and continued to the reference time. For example, he already 看过 (He has been reading newspaper). Such a problem is regarded as conflict. In the following, five cases are illustrated with examples. To resolve this conflict, a set of rules are being defined in Table 1 (R1).

**Case I:** t_e to t_s and t_r to t_s (t_e is unknown)

深信证券市场 (adv) (adv) (v是) 香港经济发展的主要动力。 (They believed that the stock market will still be the major motivation for the HK economy development.)

\[
\begin{array}{c}
\text{国庆} \\
{\text{t}_e} \\
\end{array}
\]

\[
\begin{array}{c}
\text{国庆} \\
{\text{t}_r} \\
\end{array}
\]

TR = CONTINUED(报导日期), T = t_s
**A Special Situation of Case I:** $t_e$ to $t_r$, to $t_e$ ($t_r$ is given)

基本上 (p在) (十二月前) (九月) 香港在国际金融界 (adv 强) (v占) 重要席位。 (Basically, HK will continue be important in the world global financial sector after 2000.)

$$TR = CONTINUED(二千年), T = t_r,$$

$$\begin{array}{c}
\hline
\text{二十年} & \text{二千年后} \\
\hline
\end{array}$$

$$\begin{array}{ccc}
\text{t}_e & \text{t}_r \\
\hline
\end{array}$$

$TR = PAST(十二月前)$

Case IV: $t_e$ to $t_s$ and $t_s$ ($t_r$ is given)

$$TR = PAST(十二月前)$$

Case V: Multiple implicit reference times

保险业，尤其是一级保险业务，(adv 已经) (v受到) 亚洲金融风暴的影响。 (The insurance business, especially general insurance, has been affected by the Asian financial crisis.)

$$TR = FUTURE(十二月前)$$

### Table 1: Rule set R1 for single event statements

| Case | Rule | Description |
|------|------|-------------|
| I    | $t_e$ to $t_r$, $t_e$ to $t_r$ (is unknown) |
| II   | $t_e$ to $t_r$, $t_e$ to $t_r$ (is unknown) |
| III  | $t_e$ to $t_r$, $t_e$ to $t_r$ (is unknown) |

3.4 Rules for Discovering the Relevance of Two Events (R2 & R3)

To express two relevant events is straightforward. In general, one of them is treated as the reference event, say $E_1$, which is expressed by the subordinate clause. Another one, say $E_2$, i.e. the event concerned, is expression by the main clause. The
relations (F), such as 前 (before) and 后 (after), and some special nouns, such as 时候 (when) and 期间 (during) between the two event expressions play an important role in determining their relevance in time. Also, it is noticed that the impact of \( TR(E_2) \) cannot be ignored. Practically, \( TR(E_2) \) relates \( E_2 \) to \( t_s \) or \( E_1 \). Especially for the latter, the influence of \( TR(E_2) \) is indispensable. The rules for this are being defined in the rule set R2. In addition, some special templates are also necessary for relating two events, which are being defined in the rule set R3 when \( F \) is absent.

\[
\text{(ATT}(F) = "ON") \land (\text{ATT}(E_2) = "PAST") \Rightarrow (\text{ATT}(F) = "ON") \land (\text{ATT}(E_2) = "FUTURE") .
\]

Table 2: Rule set R2 for two event statements

| Templates       | Relations |
|-----------------|-----------|
| V1 + I + V2     | AFTER    |
| V1 + V1 + V2    | AFTER    |
| V1 + (的) 同时 + V2 | SAME AS |
| V1 + 看 + V2    | SAME AS  |
| (一)边 + V1 + (一)边 + V2 | SAME AS |

Table 3: Templates in rule set R3

4 Algorithm Description

BEGIN:
input temporal statements;
(1) for a single event statement:
  IF \( t_s \) is found in a temporal statement, let \( T = t_s \);
  ELSE let \( T = t_s = \) 报道日期 (reporting date, i.e. the default value);
  ENDIF;
  DETERMINE\( (TR) \):
  IF \( \bigcap_{i \in \text{ATT}(T)} \phi \text{ATT}(T) = \psi \neq \phi \), return \( TR = \psi \);
  ELSEIF \( \bigcup_{i \in \text{ATT}(T)} \phi \text{ATT}(T) = \phi \),
    IF \( T = t_s \), return \( TR = "ON" \);
    ELSE return \( TR = "PAST" \) (default value);
    ENDIF;
ELSE check rule set R1:
  IF \( TR \) is found, return \( TR \);
  ELSE return \( TR = \phi \);
  ENDIF;
  ENDIF;
  go to END.
(2) for a declaration statement:
  IF \( t_s \) is found for \( v \), let \( T = t_s \);
  ENDIF;
  IF \( t_s \) is found for \( s \), let \( T = t_s \);
  ENDIF;
  ELSE return \( TR = "BEFORE" \) (default value);
  ENDIF;
  ENDIF;
  do DETERMINE\( (TR) \) (for the declared event).
(3) for a multiple event statement or a declared multiple event statement:
  IF \( f \) is found in a temporal statement, find \( \text{ATT}(F) \) and \( TR(E_2) \), then check rule set R2;
  IF \( TR \) is found, return \( TR \);
  ELSE return \( TR = "PAST" \) (default value);
  ENDIF;
  ENDIF;
  IF one of the events contains time definition (i.e. \( t \)), do (1);
  ELSE go to END;
  ENDIF;
  END.

5 Experiment Setup and Error Analysis

943K bytes of test data are collected from one month of financial pages of 《大公报》 (Ta Kung Bao). In total, 7924 temporal relations are discovered from the data. The distribution of temporal relations in test data is shown in Table 4. Considering the ultimate objective of this research is to find out the temporal relations embedded in sentences, the focus of the evaluation is therefore to figure out the number of the temporal relations of single event (i.e. \( TR(E) \)) and of multiple events (i.e. \( TR(E_i, E_j) \)), which are correctly marked by the program. Table 5 shows the results. Table 6 gives the order of \( TR \) classified by the program.

After analyzing the outputs, it was discovered that most errors were due to:

(1) \( t \) as a noun modifier:

Since the proposed method does not integrate the mechanism of parsing, the association between a modifier and its corresponding modifyee is not clear. In view of the task engaged, a time expression (indicated by \( t \)) could either modify a verb as an adverb, or modify a noun as a restricted modifier. Only the adverb \( t \) determines the temporal reference of the event described by
the verb. Thus, the mistake is unavoidable when a noun modifier  \( f \) appears in the text.

| Straight | Single event | Multiple events |
|----------|--------------|-----------------|
| Number   | 6235         | 603             |
| Percentage | 70.47%      | 8.12%           |

| Declared | Single event | Multiple events |
|----------|--------------|-----------------|
| Number   | 1807         | 84              |
| Percentage | 20.29%      | 1.13%           |

Table 4: Temporal expressions in the test data

| \( TR \) | No. | Corr. Mark | Accu. |
|----------|-----|------------|-------|
| \( TR(E) \) | 6742 | 6249 | 92.60% |
| \( TR(E, E) \) | 687  | 643  | 93.60% |
| Overall  | 7429 | 6892 | 92.77% |

Table 5: Experimental results of temporal relation discovery

(2) Ambiguous rules

All the rules are defined on the basis of indicators’ attributes. The majority attributes is taken to be the final inferences. However, some special words may lead to exceptional results. These special words are possible sources of errors. Following is the example of a typical ambiguous rule.

\[
FUTURE(t_e) \sqsubseteq CONTINUED(t_e) \\
\Rightarrow CONTINUED(t_e) \\
\Rightarrow (FUTURE(t_e))
\]

(a) 集团(将) (adv继续) 专注 (v发展) 电脑显示器及有关产品，扩宽产品系列。(The group will continue concentrating on the development of computer monitors, and the related in order to widen the product.

\( TR = CONTINUED \) (报导日期)

(b) (vs估计) 欧洲元在长线的走势 (v向好), (It is estimated that supported by economic factors, in the long run, Euro will gradually become better.)

\( TR = CONTINUED \) (报导日期)

**correct:** \( TR = FUTURE \) (报导日期)

**reason:** The word 进步 has the essence of CONTINUED, but it is independent to any reference time.

(3) Noisy Annotation

Some errors are resulted from noisy annotations. For example,

- **noun or verb?**
  - 切实 (v拉动) (aux了) 国民经济的 (v增长) (v)
  - (did push the growth of national economy)

- **vs or v?**
  - (t本周) 半岛家庭新盘，(v会) (vs公布) (v)
  - (the price of the new island houses will be announced this week)

- **vv or v?**
  - (t下周) 两所会就合并建议 (vv进行) (v)
  - (the two departments will vote for the suggestion of the merger on next Monday)

(4) Coreference

The program searches for a solution within a sentence bounded by a full stop. As the connections between two sentences are ignored, it is incapable to resolve the coreference problem. As such, the following two sentences are all identified as \( TR = PAST \), which is acceptable for the first and correct for the second. Nevertheless, since \( t_e \) links the current event to the event described in the last sentence (indicated by '?'), a solution of \( SAME_AS(?, \) 接受) would be more accurate. Similarly, \( BEFORE(此?, 发出) \) is more proper in the second sentence with referring to the event stated before. The problem of coreference will be studied in our future work.

(a) 另一方面，同时 (v接受) 内购登记的粉岭叠茵庭，(On the other side, the Renling Dieying ac-
6 Conclusions and Future Work

The issues of mapping linguistic patterns to temporal relations are addressed in the paper. These mapping is preconditioned on the temporal indicators and achieved on a set of pre-defined rules. The mapping mechanism was validated. On 7429 sentences describing temporal relevance, we achieved 92.77% accuracy in average.

These relations will be useful for information extraction, information retrieval and question-answering application. Once the corresponding frames have been instantiated and their slots filled after temporal natural language processing, the related temporal concepts will be linked together according to their chronological orders, to be applied as the knowledge to fulfill users' queries.

We find two interest questions as our future work.

(1) Reference Time Shift

In the current work, we considered sentences as independent units. The evaluation is also performed on this basis. However, some sentences in a article may be temporally related. They may share the same reference time which is indicated in a preceding sentence or the event time in one sentence servers as a reference point for the next. How to identify whether a reference time is continued from the preceding sentence or is the same as a omitted speech time, and how the reference times shift should be a good topic in the future work.

(2) The focus of Negation

The negation form of a verb may have two focuses. One emphasizes the event, which is expected to become the fact but, still has not yet happened. It implies that the event will take place in the future. Another emphasizes a status where the event didn't happen throughout a specified duration. Is it possible to find out the focus of the negation?
