ABSTRACT

Multiple-choice and no-choice tests were conducted at the Florida Department of Agriculture quarantine facility to determine the host specificity of the South American flower bud weevil, Anthonomus tenebrosus Boheman, intended for biological control of the exotic weed tropical soda apple (TSA), Solanum viarum Dunal in Florida, USA. Ninety-one plant species in 21 families were included in multiple-choice feeding and oviposition experiments, including the target weed and the 6 major cultivated Solanaceae: bell pepper (Capsicum annuum L.), chili pepper (C. frutescens L.), tomato (Lycopersicon esculentum Mill.), tobacco (Nicotiana tabacum L.), eggplant (Solanum melongena L.), and potato (Solanum tuberosum L.). Plant bouquets with flower-buds of 8 to 10 randomly selected plant species, always including TSA (S. viarum) were exposed to 10-20 A. tenebrosus adults for 1 to 2 weeks. Oviposition and feeding were observed twice a week. No-choice host-specificity tests were also conducted with A. tenebrosus adults using potted flowering plants. Ten adults were exposed to 29 plant species individually tested for 1 to 2 weeks. Plant species in each test were replicated 3 or 4 times. All tests showed that A. tenebrosus fed and laid eggs only on the target weed. No eggs were deposited on any of the other of the 91 plant species tested. Host-specificity tests indicated that a host range expansion of A. tenebrosus to include any of the crops, and native Solanaceae, and non-solanaceous plants tested is highly unlikely. A petition for field release in the USA was submitted to the Technical Advisory Group for Biological Control Agents of Weeds (TAG) in Oct 2007.

Key Words: host-specificity tests, weed biological control, Solanum viarum, Solanaceae

RESUMEN

Pruebas de ovoposición y alimentación (con y sin elección), se realizaron para evaluar la especificidad del picudo del botón floral, de origen suramericano, Anthonomus tenebrosus Boheman, como agente potencial para control biológico de bola de gato, Solanum viarum Dunal en los Estados Unidos. Las pruebas se efectuaron en la cuarentena del Departamento de Agricultura de la Florida. Noventa y una especies de plantas, en 21 familias, fueron incluidas en las pruebas de especificidad de múltiples elección, incluyendo la maleza objetivo y las seis plantas cultivadas pertenecientes a la familia Solanaceae más importantes: chile dulce (Capsicum annuum L.), chile (Capsicum frutescens L.), tomate (Lycopersicon esculentum Mill.), tabaco (Nicotiana tabacum L.), berenjena (Solanum melongena L.), y papa (Solanum tuberosum L.). En cada prueba se utilizaron racimos florales de ocho a diez plantas escogidas al azar incluyendo siempre la planta objetivo las cuales fueron expuestas a 10-20 adultos de A. tenebrosus por una a dos semanas. Registros de alimentación y ovoposición fueron realizados dos veces por semana. Pruebas de alimentación/ovoposición sin elección fueron también realizadas usando plantas en floración. Diez adultos fueron expuestos a 29 especies de plantas en forma individual por una a dos semanas. Cada prueba tuvo tres o cuatro repeticiones. Las pruebas mostraron que A. tenebrosus se alimentó y colocó posturas solo en bola de gato. Ninguna postura fué depositada en las otras 90 especies de plantas evaluadas. Las pruebas indicaron que la posibilidad de A. tenebrosus de llegar a ser una plaga de las Solanaceae cultivadas es muy remota. La solicitud al comité TAG para liberar el picudo en los Estados Unidos fue presentada en octubre 2007.

Tropical soda apple (TSA), Solanum viarum Dunal (Solanaceae), is an invasive weed native to southeastern Brazil, northeastern Argentina, Paraguay, and Uruguay that has invaded Florida grasslands and natural ecosystems. In 1988, TSA was first reported in the USA in Glades County, Florida (Coile 1993; Mullahay & Colvin 1993); the introduction pathway is unknown. In 1993, a survey of beef cattle operations in south Florida estimated 157,145 ha of infested pasture land, twice the infestation present in 1992 (Mullahay et al. 1994). The infested area increased to more than
303,000 ha in 1995-96 (Mullahey et al. 1998). Currently, more than 404,000 ha are believed to be infested in Florida (Medal et al. 2010b). Due, at least in part, to favorable environmental conditions, the lack of natural enemies (herbivores and pathogens), and seed dispersal by wildlife and cattle feeding on the fruits. TSA has been spreading rapidly and has been observed in the majority of the counties in Florida and also in Alabama, Georgia, Louisiana, Mississippi, North Carolina, Pennsylvania, South Carolina, Tennessee, Texas, and Puerto Rico (Bryson & Byrd Jr. 1996; Dowler 1996; Mullahey et al. 1993, 1998; Medal et al. 2003, 2010a). Although TSA has been reported in Pennsylvania and Tennessee, it is highly probable that does not overwinter in these states. Patterson (1996) studied the effects of temperatures and photoperiods on TSA in controlled environmental chambers and speculated that the range of TSA could expand northward into the midwestern US. 

S. viarum was placed on the Florida and Federal Noxious Weed Lists in 1995.

TSA typically invades improved pastures, where it reduces livestock carrying capacity. Forage and stems are unpalatable to cattle; dense stands of the prickly shrub prevent access of cattle to shaded areas, which results in summer heat stress (Mullahey et al. 1998). TSA control costs for Florida ranchers were estimated at $6.5 to 16 million annually (Thomas 2007), and economic losses from cattle heat stress alone were estimated at $2 million (Mullahey et al. 1998). TSA is a reservoir for at least 6 crop viruses (potato leafroll virus, potato virus Y, tomato mosaic virus, tomato mottle virus, tobacco etch virus, and cucumber mosaic virus) and the early blight of potato and tomato fungus, Alternaria solani. The host ranges of TSA and its natural enemies in South America was conducted by Bohe- man (Coleoptera: Curculionidae). This insect was collected on TSA in Rio Grande do Sul, Brazil (29.66465°S, 50.80171°W) by the late Daniel Gandolfó and Julio Medal in April 2000. The identity of A. tenebrosus was confirmed by Drs. Wayne Clark (Auburn University, AL) and Germano Rosado Neto (Universidade Federal do Paraná in Curitiba, Brazil). Voucher specimens of A. tenebrosus are deposited at Auburn University, Alabama, at the Universidade Federal do Paraná - Curitiba campus, Brazil, and at the Florida State Collection of Arthropods, Division of Plant Industry in Gainesville, Florida. This species does not have a common name in South America. The only known A. tenebrosus host plants in South America are S. viarum and S. acculeatisimum.

The biology of A. tenebrosus was studied by Davis (2007) at the quarantine facility in Gainesville, Florida. Eggs are inserted individually into TSA flower-buds, and hatch in 3-5 days. Larvae are cream-colored with a yellowish brown head capsule. They feed on the contents of the flower-bud, and this feeding prevents the flower-bud from opening. There is typically 1 larva, but occasionally 2 larvae in a single flower-bud. As larval feeding progresses, the flower-bud senescence and drop from the plant. Three larval stadia are completed in 7-13 days. The pupal stage is completed in 3-7 days inside the fallen flower bud. Pupae resemble the adult in form; they are cream-colored but darken shortly before eclosion. Emerging adults chew their way out of the flower-bud. De-
velopment from egg to adult stage lasts 11-69 days. Longer developmental times are apparently not associated with seasonal differences as they occurred throughout the year. Adults can live up to 210 days under laboratory conditions. Adult size appears to be related to food abundance during development rather than beetle sex. Copulation has been observed a few hours after adult emergence and throughout the oviposition period. At least 7-8 generations per year can occur under laboratory conditions (temperature 24° ± 3C, relative humidity 50-70%) conditions.

**Materials and Methods**

**Host Specificity Tests**

Laboratory host specificity tests with *A. tenebrosus* adults were conducted from May 2000 to January 2003 at the Florida Department of Agriculture and Consumer Services-Division of Plant Industry quarantine facility in Gainesville, Florida. Open field host-specificity tests were conducted at the Universidade Federal do Paraná Agricultural Experiment Station in Paraná state, Brazil from October 2005 to March 2007. For Florida tests, *A. tenebrosus* adults were collected from TSA plants in Rio Grande do Sul, Brazil and introduced onto caged plants of TSA plants growing in 1-gallon pots to establish a laboratory colony in quarantine.

In this article we report the results of various host-specificity tests with the flower-bud weevil *A. tenebrosus*, to assess its possible use as biological control agent of the non-native weed tropical soda apple.

**Multiple-Choice Feeding and Oviposition Tests**

Ninety-one plant species in 21 families were included in the feeding oviposition preference tests at the Gainesville quarantine (Table 1). Tested plants included 53 species in the family of the target weed (Solanaceae), 26 of which were from the genus *Solanum* and 27 from 14 other genera that include plants of agricultural or ecological importance. Ten species represented 5 families (Boraginaceae, Convolvulaceae, Ehretiaceae, Nolaneaceae, Polemoniaceae) very close related to Solanaceae within the order Polemoniales (Heywood 1993) were also included. Twenty-eight plant species representing 15 families, most of them with economic and/or environment value in North America, were also tested. The target weed (*S. viarum*), and other 9 plant species in Solanaceae were tested at least 3 times (Table 1). These included the natives *Solanum donianum* Walpers, listed as a threatened plant in Florida (Coile 1998), and *S. americanum* Mill, 2 non-native-weeds (*S. taymifolium* Dunal, *S. torvum* Sw.), and the 5 major cultivated Solanaceae (bell pepper, *Capsicum annuum* L., tomato, *Lycopersicon esculentum* Mill., tobacco, *Nicotiana tabacum* L., eggplant, *Solanum melongena* L., and potato, *Solanum tuberosum* L.). Bouquets of leaves and flower-buds of 8 to 10 plant species, always including TSA were simultaneously exposed to 10-20 *A. tenebrosus* adults (approximately 50% males and 50% females) in clear plastic round containers (26 cm diameter by 9 cm height, with four 4-7 cm diameter vents drilled along the sides of the container to allow for air circulation). At the beginning of each test, the insects were placed at the bottom center of each container to allow them to choose any tested plants. Plant species in each test were replicated 3-4 times (1 replication of tested plants in each separate container). Bouquets were exposed to *A. tenebrosus* adults for 1 to 2 weeks. Observations of oviposition and feeding were made twice a week, and consumed bouquets were replaced as needed. Flower-buds were checked for oviposition and eggs were counted weekly. On the last day of each experiment, flower-buds were scored for feeding damage, and eggs laid on them were counted. Leaf and flower bud area consumed was visually estimated using a scale from 0 to 5 (0 = no feeding, 1 = probing or <5% of area consumed, 2 = light feeding or 5-20% of the area, 3 = moderate feeding or 21-40%, 4 = heavy feeding or 41-60%, and 5 = intense feeding or >60% of the area consumed).

**No-Choice Adult Feeding and Oviposition Tests**

No-choice host specificity tests were also conducted with *A. tenebrosus* adults at the Gainesville-quarantine facility using potted plants (20-60 cm height) in cages. Cages were made of clear-plastic cylinders (15 cm diam, 50-60 cm height), with a mesh screen at the top and covering 6 circular holes (6 cm diam) located in pairs at the bottom, middle, and upper part of the cylinder to allow for air circulation. *A. tenebrosus* adults were exposed to 29 plant species in 3 families, including the native *S. donianum*, and all major cultivated Solanaceae (Table 2). Five to 7 plant species with flower-buds were individually tested each time due to limited cage numbers. Plants were exposed to 10 *A. tenebrosus* adults (5 males, 5 females) for 1 to 2 weeks; each test plant was replicated 3 or 4 times. Adults were *F₀* or *F₁* progeny from adults originally collected in southern Brazil and reared in quarantine on TSA. Adults had either recently eclosed from pupae or were still young less than 1 week old. Plants were replaced as needed. At the end of the testing periods, feeding and oviposition were recorded.

**First Field Experiment in Brazil**

A multiple-choice, open field experiment was conducted at the Universidade Federal do Paraná, Agriculture Experimental Farm ‘Canguiri’. A.

**Second Field Experiment in Brazil**

Another multiple-choice, open field experiment exposing *A. tenebrosus* adults to flowering eggplant cv. ‘Black Beauty’, tomato, potato, and...
bell pepper, but not TSA, was conducted at the Universidade Federal do Paraná, Agriculture Experimental Farm ‘Canguiri’, Brazil from Dec 2006 to Mar 2007. Control plots with flowering TSA plants alone, were also established at the Neotropical Biological Control Laboratory in Curitiba located approximately 45 km from the cultivated crop plots to prevent plant species interference. Distance between plants was similar to the first experiment. Field collected A. tenebrosus weevils were released into crop and TSA plots (80 and 76 adults, respectively). Beetles were randomly released in groups (6-10) on the ground but not on any test plant. Evaluations (visual estimation of number of insects and feeding) were made weekly checking thoroughly each of the plants tested.

RESULTS AND DISCUSSION

Multiple-Choice Feeding-Oviposition Tests

In the quarantine multiple-choice tests, A. tenebrosus adults fed moderately to intensively (>20% of the area offered) on S. viarum, the target weed (Table 1). Weevils did some probing or exploratory feeding (<5% of the area offered) on S. tampicense Dunal (an exotic weed of Mexico-Central America-Caribbean origin and established and expanding in central-south Florida), on S. sisymbriifolium Lam., and S. jasminoides Puxt. (weeds of South-American origin also present in Florida), and on eggplant cv. ‘Asian Long Purple’ (crop of economic importance). No feeding was observed on any of the other 86 plant species in 21 families that were tested. A. tenebrosus adults laid from 5 to 9 eggs inside TSA flower-buds during the 1-2 week period of the test (Table 1). No eggs were deposited on any of the other 90 plant species tested, including the threatened S. donatunum. Although minor A. tenebrosus feeding occurred on eggplant in quarantine, this insect has never been recorded attacking eggplant in South America. Expanded host ranges of weed-biocontrol insects under confined laboratory conditions have been reported by South African researchers (Neser et al. 1988; Hill & Hulley 1995; Ockers et al. 1995; Hill & Hulley 1996; Ockers 1996). They indicated that almost all agents tested for biocontrol of Solanum weeds have fed on closely related plant species that are never attacked under natural conditions. For example, Gratiana spadicea (Klug) (Coleoptera: Chrysomelidae) screened as a potential biocontrol agent of S. sisymbriifolium in South-Africa (Hill & Hulley 1995), fed and completed development on eggplant in the laboratory. In 1994, this insect was released in South-Africa based mainly on the lack of records as an eggplant pest in South America. Gratiana spadicea is established on S. sisymbriifolium with no reports of attacks in South African eggplant fields. Multiple choice tests conducted at the USDA-South American Biological Control Laboratory in Hurlingham, Argentina with Anthonomus sisymbrii Hustache by late Daniel Gandolfo, showed this weevil fed and lay eggs on eggplant and potato, although the number of eggs lay on these crops was significantly lower than on TSA. He also reported that 75% of the eggs on potato and 25% on eggplant were abnormally oviposited outside the flower-buds. Gandolfo indicated that A. sisymbrii could use eggplant, and possibly other Solanum, at least for feeding purposes that may result in an economic impact (Gandolfo et al. 2004). The only known natural hosts of A. sisymbrii are S. sisymbriifolium, S. viarum, and S. aculeatissimum (Medal unpublished data). To corroborate the specificity and safety of A. tenebrosus, a weevil related to A. sisymbrii, 2 open field experiments (discussed later) were conducted in Brazil, which indicated that A. tenebrosus did not represent a threat to eggplant and other economic crops tested under natural conditions and it is safe as a biological control agent of TSA.

No-Choice Adult Feeding Tests

Starvation (no-choice) tests with A. tenebrosus adults exposed to individual potted plants (29 species in 3 families) in quarantine cages indicated that this insect fed and laid eggs (range: 4-11; average, 8 eggs per female) only on TSA (Table 2). Feeding on TSA was moderate to intense (>21% of the area offered) compared to a probing or exploratory feeding (<5% observed on S. elaeagnifolium, S. tampicense, and on S. torum. No eggs were laid on any of the 28 non-target plant species tested including 4 eggplant cultivars (‘Black Beauty’, ‘Classic’, ‘Market’, ‘Asian Long Purple’).

First Field Experiments in Brazil

In the open-field planted with TSA, bell-pepper, tomato, potato, and eggplant, A. tenebrosus adults (100) fed and laid eggs, and larvae developed only on TSA. A total of 83 eggs, 21 larvae, and 51 adults of A. tenebrosus were recorded on TSA plants. Feeding on TSA flower-buds was moderate to heavy (21 to 50% of the area). No feeding was observed on any of the Solanaceous crops tested. This field test confirms that A. tenebrosus feeds and develops only on TSA and does not represent a threat to eggplant, tomato, potato, or bell-pepper.

Second Field Experiment in Brazil

The field test exposing A. tenebrosus adults to eggplant, tomato, potato, and bell-pepper, showed that no adults or immature stages were found on these crops tested when TSA plants were not
present. In a separate plot, A. tenebrosus feeding on TSA flower buds was moderate (21-30%), contrary to no-feeding on the crops tested. A total of 124 eggs, 72 larvae, and 45 adults of A. tenebrosus were recorded on TSA plants. This test showed that A. tenebrosus adults fed and laid eggs, and larvae developed only on TSA, with no utilization of eggplant, potato, tomato, and bell pepper when TSA is not present.

The laboratory and open-field experiments indicated that no A. tenebrosus feeding damage and reproduction on the native solanaceous plants and crops tested are likely to occur. It is expected that this weevil will complement the TSA damage by G. boliviana in south and central Florida.

ACKNOWLEDGMENTS

We thank Howard Frank (University of Florida), and Julieta Brambila (United States Department of Agriculture, Animal and Plant Health Inspection Service) and three anonymous reviewers for reviewing the manuscript. We also thank Wayne Clark (Auburn University), and Germano Rosado Neto (Universidade Federal do Paraná - Curitiba, Brazil) for the identification of Anthonomus tenebrosus. This research was funded by USDA-APHIS.
