Abstract: We study the Higgs sector of the secluded $U(1)'$-extended MSSM (sMSSM) focusing on CP violation. Using the one-loop effective potential that includes contributions from quarks and squarks in the third generation, we search for the allowed region under theoretical and experimental constraints. It is found that the possible region for the electroweak vacuum to exist is quite limited, depending on the parameters in the model. The masses and couplings of the Higgs bosons are calculated with/without CP violation. Even at the tree level, CP violation is possible by complex soft SUSY breaking masses. Similar to the CPX scenario in the MSSM, the scalar-pseudoscalar mixing enables the lightest Higgs boson mass to become smaller than the $Z$ boson mass while the coupling with the $Z$ boson is sufficiently suppressed to avoid the LEP experimental constraints. However, unlike the CPX scenario, large $\mu$ and $A$ are not required for the realization of large CP violation. The typical spectrum of the SUSY particles is thus different. We also investigate the possible upper bound of the lightest Higgs boson in the case of spontaneous CP violation. The maximal value of it can reach above 100 GeV with maximal CP-violating phases.

Keywords: Secluded minimal supersymmetric standard model, CP violation, Higgs boson.
1. Introduction

Many new physics models have been proposed to address the issue of the so-called gauge hierarchy problem that cannot be resolved within the framework of the standard model (SM). Supersymmetric extensions of the SM have been paid much attention as possible solutions to this problem. In particular, the minimal supersymmetric standard model (MSSM) can solve not only this problem but also cosmological problems such as dark matter and baryon asymmetry of the Universe and so on. Nevertheless, the model still has an unattractive feature: the $\mu$ problem, where $\mu$ appears in the mass term of the higgsinos. As long as no special symmetry exist in the theory, the scale of $\mu$ is supposed to be the grand unified theory (GUT)/Planck scale from the naturalness point of view. However, once the electroweak symmetry is broken, the scale of $\mu$ should be at about the $W$ boson mass. One direction to provide a natural scale for $\mu$ is to introduce a gauge singlet field $(S)$ into the MSSM. Several variations of this extension have been proposed: the next-to-MSSM (NMSSM) \cite{1,2,3}, the nearly MSSM (nMSSM) \cite{4,5}, the $U(1)'$-extended MSSM (UMSSM) \cite{6,7,8}, and the secluded $U(1)'$-extended MSSM (sMSSM) \cite{9,10,11}. Comparisons among these singlet-extended MSSM models can be found in Refs. \cite{11}. A common feature
in these models is that there is no fundamental $\mu$ term in the superpotential. After the symmetry breaking associated with the singlet field $S$, the $\mu$ term is effectively generated by the product of the dimensionless coupling and the vacuum expectation value (VEV) of $S$, and thus no fine tuning is required. Because of the introduction of singlet field(s), such models have richer physics than the MSSM.

In this paper, we focus on the Higgs sector of the sMSSM with particular emphasis on $CP$ violation. The sMSSM is a string-inspired model whose particle content of the Higgs sector comprises two Higgs doublets and four Higgs singlets. They are charged under the $SU(3)_C \times SU(2)_L \times U(1)_Y \times U(1)'$ gauge symmetry. Once the additional $U(1)'$ symmetry is introduced, a new gauge boson $Z'$ must exist in the model and can mix with the ordinary $Z$ boson $[12, 13]$. From the negative results of $Z'$ search at LEP, the magnitude of the mixing angle between them (denoted by $\alpha_{ZZ'}$) must be suppressed at $O(10^{-3})$ level $[14]$. The sMSSM provides an explanation for such a $Z$-$Z'$ hierarchy in a natural way. If the $U(1)'$ symmetry is broken around the TeV scale, the VEVs of the additional three Higgs singlets ($S_1, S_2, S_3$) are expected to be of $O(\text{TeV})$. This makes $\alpha_{ZZ'}$ small enough to escape from the current experimental bounds on the $Z'$ boson.

Due to the extension in the Higgs sector, it is possible to break the $CP$ symmetry explicitly and spontaneously at the tree level, which is forbidden in the MSSM. It is well known that the Kobayashi-Maskawa $CP$-violating phase $[15]$ in the SM is too small to generate sufficiently large baryon asymmetry of the Universe as observed today $[16]$. Therefore, additional $CP$-violating phases are required for successful baryogenesis. So far, electroweak baryogenesis have been studied in the singlet extended MSSM models: the NMSSM $[17]$, the nMSSM $[1, 18]$, the UMSSM $[19]$ and the sMSSM $[20]$. A detailed analysis of the connection between $CP$ violation and baryogenesis, however, is beyond the scope of this paper.

In our analysis, we use the one-loop effective potential that includes contributions from the third-generation quarks and squarks. We search for the parameter space allowed by imposing both theoretical and experimental constraints on the model. Owing to the presence of extra Higgs singlet fields, the tadpole conditions defined by the first derivatives of the Higgs potential do not always give the desired vacuum, $v = 246 \text{ GeV}$. Therefore, we also numerically check whether or not the minimum is located at 246 GeV. We find that the possible region for the electroweak vacuum is quite limited, depending on the model parameters.

In the sMSSM, the only source of physical $CP$ violation at the tree level comes from the relative phase between the soft SUSY breaking masses and the phases of the Higgs fields. We calculate the Higgs boson masses and the couplings between the gauge bosons and Higgs bosons in the cases of explicit $CP$ violation (ECPV) and spontaneous $CP$ violation (SCPV). It is found that due to the new $CP$-violating phases, the mass of the lightest Higgs boson can be smaller than that of the $Z$ boson. On the other hand, the coupling of the lightest Higgs boson to the $Z$ boson is sufficiently suppressed, similar to the CPX scenario in the MSSM $[21, 22, 23]$. Nonetheless, the $\mu$ and $A$ parameters are not necessarily large in this model, making the spectrum of SUSY particles different from the CPX scenario.

We also provide a bound on the lightest Higgs boson mass in the case of SCPV.
Table 1: Particle content in the Higgs sector of sMSSM

| Higgs | $SU(3)_C \times SU(2)_L \times U(1)_Y \times U(1)'_{Q'}$ |
|-------|------------------------------------------------|
| $H_d$ | $(1, 2, -1/2, Q_{H_d})$ |
| $H_u$ | $(1, 2, 1/2, Q_{H_u})$ |
| $S$   | $(1, 1, 0, Q_S)$ |
| $S_1$ | $(1, 1, 0, Q_{S_1})$ |
| $S_2$ | $(1, 1, 0, Q_{S_2})$ |
| $S_3$ | $(1, 1, 0, Q_{S_3})$ |

Depending on the mass of charged Higgs bosons, the upper bound can reach above 100 GeV with maximal CP violation.

The paper is organized as follows. In Section 2, we introduce the model and define the CP-violating phases in a reparametrization invariant way. Theoretical and experimental constraints are studied in Section 3. We examine the effects of CP violation on the Higgs boson masses and couplings in Section 4. In particular, the explicit CP-violating case is presented in Subsection 4.1 and the spontaneous CP-violating case in Subsection 4.2. The discussion about electric dipole moments (EDMs) is presented in Subsection 4.3. Finally, we summarize the work in Section 5. Formulas of the Higgs boson masses are given in Appendix A.

2. The model

The particle content in the Higgs sector of sMSSM comprises two Higgs doublets ($H_d, H_u$) and four Higgs singlets ($S, S_1, S_2, S_3$). As listed in Table 1, each field is charged under the $SU(3)_C \times SU(2)_L \times U(1)_Y \times U(1)'_{Q'}$ gauge symmetry. Though it is desirable to have $U(1)'_{Q'}$ charges ($Q'$s) chosen to make the model anomaly free, a complete analysis of anomaly cancellation is beyond the scope of this paper. Neither will we address the gauge coupling unification issue here as it requires the knowledge of full particle spectrum in the model. Instead, we focus exclusively on the Higgs sector. The model which we are considering is extended so that no dimensionful parameter exists in the superpotential $W$:

$$W \ni -\epsilon_{ij} \lambda S H_d^i H_u^j - \lambda_S S_1 S_2 S_3,$$

where $\lambda$ and $\lambda_S$ are the dimensionless couplings. Unlike the NMSSM, the $U(1)'_{Q'}$ symmetry forbids a cubic term in the superpotential which can cause a domain wall problem if the $Z_3$ symmetry is broken spontaneously. Once the Higgs singlet $S$ develops a VEV, an effective $\mu$ term is generated by $\mu_{\text{eff}} = \lambda \langle S \rangle$. Therefore, the scale of $\mu_{\text{eff}}$ is determined by the soft

\(^{1}\text{To be anomaly free, exotic chiral supermultiplets are generally required}^{\cite{7, 24, 25}}. \text{For our purpose, we assume that they are heavy enough not to affect the phenomenology at the electroweak scale.}\)
SUSY breaking terms. In Eq. (2.1) only, there is no interaction between the secluded Higgs singlet fields $S_{1,2,3}$ and the two Higgs doublets $H_u,d$ and singlet $S$.

The Higgs potential at the tree level is given by the $F$, $D$- and soft SUSY breaking terms:

$$V_0 = V_F + V_D + V_{\text{soft}},$$

(2.2)

where each term reads

$$V_F = |\lambda|^2 \{ |\epsilon_{ij} \Phi^i_d \Phi^j_u|^2 + |S|^2 (\Phi^i_d \Phi^i_d + \Phi^j_u \Phi^j_u) \} + |\lambda_S|^2 (|S_1 S_2|^2 + |S_2 S_3|^2 + |S_3 S_1|^2),$$

(2.3)

$$V_D = \frac{g_2^2 + g_1^2}{8} (\Phi^i_d \Phi^i_d - \Phi^j_u \Phi^j_u)^2 + \frac{g_2^2}{2} |\Phi^i_d \Phi^i_u|^2$$

$$+ \frac{g_1^2}{2} \left( Q_{H_d} \Phi^i_d \Phi^i_d + Q_{H_u} \Phi^j_u \Phi^j_u + Q_S |S|^2 + \sum_{i=1}^{3} Q_{S_i} |S_i|^2 \right)^2, \tag{2.4}$$

$$V_{\text{soft}} = m_1^2 \Phi^i_d \Phi^i_d + m_2^2 \Phi^j_u \Phi^j_u + m_S^2 |S|^2 + \sum_{i=1}^{3} m_{S_i}^2 |S_i|^2$$

$$- (\epsilon_{ij} \lambda A_{\lambda} S \Phi^i_d \Phi^j_u + \lambda S A_{\lambda} S_1 S_2 S_3 + m_S^2 S S_1 + m_S^2 S S_2 + m_S^2 S S_3 + m_S^2 S_1 S_2 + \text{h.c.}), \tag{2.5}$$

where $g_2, g_1$ and $g_1'$ are the $SU(2), U(1)$ and $U(1)'$ gauge couplings, respectively. We will take $g_1' = \sqrt{5/3} g_1$ as motivated by the gauge unification in the simple GUTs. The soft SUSY breaking masses $m_{S S_1}$ and $m_{S S_2}$ are introduced to break the two unwanted global $U(1)$ symmetries. This choice is called Model I, where $Q_S = -Q_{S_1} = -Q_{S_2} = Q_{S_3}/2$ and $Q_{H_d} + Q_{H_u} + Q_S = 0$. Although the other choice dubbed Model II is also possible, we will not pursue it in this paper since there is no room for physical $CP$-violating phases in the tree-level potential \[\text{I}\]. The secluded sector $(S_1, S_2, S_3)$ can interact with the ordinary ones $(H_d, H_u, S)$ through the $g_1'$ coupling, $m_{S S_1}$ and $m_{S S_2}$.

In general, the following five parameters can be complex in the Higgs potential:

$$\lambda A_{\lambda}, \lambda S A_{\lambda S}, m_{S S_1}^2, m_{S S_2}^2, m_{S_1 S_2}^2 \in \mathbb{C}. \tag{2.6}$$

After rephasing the Higgs fields, however, four of them can be made real and only one $CP$-violating phase is physical. In the following, we define the $CP$-violating phase in a reparameterization invariant way. It should be noted that in the UMSSM no physical $CP$-violating phase can survive after rotating the Higgs fields and, therefore, the $CP$ symmetry cannot be violated in the tree-level Higgs potential. We parameterize the Higgs fields as

$$\Phi_d = e^{i\theta_1} \left( \frac{1}{\sqrt{2}} (v_d + h_d + i a_d) \right), \quad \Phi_u = e^{i\theta_2} \left( \frac{1}{\sqrt{2}} (\phi^+_u) \right),$$

(2.7)

$$S = \frac{e^{i\theta_S}}{\sqrt{2}} (v_S + h_S + i a_S), \quad S_i = \frac{e^{i\theta_{S_i}}}{\sqrt{2}} (v_{S_i} + h_{S_i} + i a_{S_i}), \quad (i = 1 - 3),$$

(2.8)

where $v = \sqrt{v_d^2 + v_u^2} \simeq 246$ GeV. The nonzero $\theta$‘s can break the $CP$ symmetry spontaneously. However, the $\theta$’s are not independent. Here we define the four gauge invariant
phases by
\[
\varphi_1 = \theta_S + \theta_{S_1}, \quad \varphi_2 = \theta_S + \theta_{S_2}, \quad \varphi_3 = \theta_S + \theta_1 + \theta_2, \quad \varphi_4 = \theta_{S_1} + \theta_{S_2} + \theta_{S_3}. \tag{2.9}
\]

For later convenience, we also define \(\varphi_{12} = -\varphi_1 + \varphi_2\). The first derivative of the Higgs potential with respect to each Higgs field must vanish (tadpole conditions). At the tree level, we obtain

\[
\frac{1}{v_d} \left\langle \frac{\partial V_0}{\partial h_d} \right\rangle = m_2^2 + \frac{g_2^2 + g_3^2}{8} (v_d^2 - v_u^2) - R_S \frac{v_u v_S}{v_d} + \frac{|\lambda|^2}{2} (v_d^2 + v_S^2) + \frac{g_3^2}{2} Q_{H_u} \Delta = 0, \tag{2.10}
\]

\[
\frac{1}{v_u} \left\langle \frac{\partial V_0}{\partial h_u} \right\rangle = m_2^2 + \frac{g_2^2 + g_3^2}{8} (v_d^2 - v_u^2) - R_S \frac{v_d v_S}{v_u} + \frac{|\lambda|^2}{2} (v_d^2 + v_S^2) + \frac{g_3^2}{2} Q_{H_u} \Delta = 0, \tag{2.11}
\]

\[
\frac{1}{v_S} \left\langle \frac{\partial V_0}{\partial h_S} \right\rangle = m_S^2 - \text{Re}(m^2_{S_1} e^{i\varphi_1}) \frac{v_{S_1}}{v_S} - \text{Re}(m^2_{S_2} e^{i\varphi_2}) \frac{v_{S_2}}{v_S} - R_S \frac{v_d v_u}{v_S} + \frac{|\lambda|^2}{2} (v_d^2 + v_S^2) + \frac{g_3^2}{2} Q_S \Delta = 0, \tag{2.12}
\]

\[
\frac{1}{v_{S_1}} \left\langle \frac{\partial V_0}{\partial h_{S_1}} \right\rangle = m_{S_1}^2 - \text{Re}(m^2_{S_1} e^{i\varphi_1}) \frac{v_{S_1}}{v_{S_1}} - \text{Re}(m^2_{S_2} e^{i\varphi_2}) \frac{v_{S_2}}{v_{S_1}} - R_S \frac{v_{S_1} v_{S_2}}{v_{S_1}} + \frac{|\lambda|^2}{2} (v_{S_1}^2 + v_{S_2}^2) + \frac{g_3^2}{2} Q_{S_1} \Delta = 0, \tag{2.13}
\]

\[
\frac{1}{v_{S_2}} \left\langle \frac{\partial V_0}{\partial h_{S_2}} \right\rangle = m_{S_2}^2 - \text{Re}(m^2_{S_1} e^{i\varphi_1}) \frac{v_{S_2}}{v_{S_2}} - \text{Re}(m^2_{S_2} e^{i\varphi_2}) \frac{v_{S_2}}{v_{S_2}} - R_S \frac{v_{S_1} v_{S_2}}{v_{S_2}} + \frac{|\lambda|^2}{2} (v_{S_1}^2 + v_{S_2}^2) + \frac{g_3^2}{2} Q_{S_2} \Delta = 0, \tag{2.14}
\]

\[
\frac{1}{v_{S_3}} \left\langle \frac{\partial V_0}{\partial h_{S_3}} \right\rangle = m_{S_3}^2 - R_S \frac{v_{S_1} v_{S_2}}{v_{S_3}} + \frac{|\lambda|^2}{2} (v_{S_1}^2 + v_{S_2}^2) + \frac{g_3^2}{2} Q_{S_3} \Delta = 0, \tag{2.15}
\]

\[
\frac{1}{v_d} \left\langle \frac{\partial V_0}{\partial a_d} \right\rangle = \frac{1}{v_u} \left\langle \frac{\partial V_0}{\partial a_u} \right\rangle = I_\lambda v_S = 0, \tag{2.16}
\]

\[
\left\langle \frac{\partial V_0}{\partial a_S} \right\rangle = \text{Im}(m^2_{S_1} e^{i\varphi_1}) v_{S_1} + \text{Im}(m^2_{S_2} e^{i\varphi_2}) v_{S_2} + I_\lambda v_d v_u = 0, \tag{2.17}
\]

\[
\left\langle \frac{\partial V_0}{\partial a_{S_1}} \right\rangle = \text{Im}(m^2_{S_1} e^{i\varphi_1}) v_S - \text{Im}(m^2_{S_1} e^{i\varphi_2}) v_{S_2} + I_\lambda v_{S_2} v_{S_3} = 0, \tag{2.18}
\]

\[
\left\langle \frac{\partial V_0}{\partial a_{S_2}} \right\rangle = \text{Im}(m^2_{S_2} e^{i\varphi_2}) v_S + \text{Im}(m^2_{S_1} e^{i\varphi_2}) v_{S_1} + I_\lambda v_{S_1} v_{S_3} = 0, \tag{2.19}
\]

\[
\left\langle \frac{\partial V_0}{\partial a_{S_3}} \right\rangle = I_\lambda v_{S_1} v_{S_2} = 0, \tag{2.20}
\]

with

\[
\Delta = Q_{H_d} v_d^2 + Q_{H_u} v_u^2 + Q_S v_S^2 + \sum_{i=1}^{3} Q_i v_{S_i}^2, \tag{2.21}
\]

\[
R_\lambda = \frac{\text{Re}(\lambda A e^{i\varphi_3})}{\sqrt{2}}, \quad I_\lambda = \frac{\text{Im}(\lambda A e^{i\varphi_3})}{\sqrt{2}}. \tag{2.22}
\]
Table 2: Physical Higgs bosons in the sMSSM

|                | CP-even Higgs bosons | CP-odd Higgs bosons | charged Higgs bosons |
|----------------|----------------------|---------------------|----------------------|
| CPC            | \(H_1, H_2, H_3, H_4, H_5, H_6\) | \(A_1, A_2, A_3, A_4\) | \(H^+, H^-\)          |
| CPV            | \(H_1, H_2, H_3, H_4, H_5, H_6, H_7, H_8, H_9, H_{10}\) | \(H^+, H^-\)          |

\[
R_\lambda = \frac{\text{Re}(\lambda_S A_\lambda e^{i\varphi_4})}{\sqrt{2}}, \quad I_\lambda = \frac{\text{Im}(\lambda_S A_\lambda e^{i\varphi_4})}{\sqrt{2}}, \quad (2.23)
\]

where \(\langle \cdots \rangle\) is defined such that all Higgs fluctuating fields are taken to be zero. Here all the Higgs VEVs are assumed to be nonzero. For some parameter sets, however, a global minimum can be located at the place where some of the Higgs VEVs are zero. Of course, such a minimum cannot be found from Eqs. (2.10)-(2.20). We will discuss the method of minimum search in Section 3. In the current investigation, we do not specify any SUSY breaking scenario. Hence the soft SUSY breaking masses are given by the tadpole conditions for the CP-conserving Higgs fields Eqs. (2.10)-(2.15). After solving the tadpole conditions for the CP-odd Higgs fields from Eqs. (2.16)-(2.20), we find

\[
I_\lambda = I_{\lambda_S} = 0, \quad (2.24)
\]

\[
\text{Im}(m^2_{SS_1} e^{i\varphi_1}) = \text{Im}(m^2_{SS_2} e^{i\varphi_{12}}) \frac{v_{S_2}}{v_S}, \quad (2.25)
\]

\[
\text{Im}(m^2_{SS_2} e^{i\varphi_2}) = -\text{Im}(m^2_{SS_1} e^{i\varphi_{12}}) \frac{v_{S_1}}{v_S}. \quad (2.26)
\]

The CP-violating phases must satisfy Eqs. (2.24)-(2.26) for the vacuum. As a convention, we choose the independent physical CP-violating phase to be \(\theta_{\text{phys}} = \text{Arg}(m^2_{SS_1} + \varphi_{12})\).

2.1 The mass matrix of the neutral Higgs bosons

The squared mass matrix of the neutral Higgs bosons is a 12 × 12 symmetric matrix taking the form

\[
\frac{1}{2} \left( H^T A^T \right) \mathcal{M}^2_N \left( H A \right), \quad \mathcal{M}^2_N = \left( \begin{array}{cc} \mathcal{M}^2_S & \mathcal{M}^2_{SP} \\ (\mathcal{M}^2_{SP})^T & \mathcal{M}^2_P \end{array} \right), \quad (2.27)
\]

where \(H^T \equiv (h^T_O = (h_d \ h_u \ h_S) \ h_S^T = (h_{S_1} \ h_{S_2} \ h_{S_3})), \ A^T \equiv (a^T_O = (a_d \ a_u \ a_S) \ a_S^T = (a_{S_1} \ a_{S_2} \ a_{S_3})). \) The subscripts \(O, S\) on \(h, a\) denote ‘ordinary’ and ‘secluded’, respectively. In Table 2, the physical Higgs bosons in this model are listed for both the CP-conserving (CPC) and the CP-violating (CPV) cases. After the symmetry breaking, two neutral Nambu-Goldstone bosons \(G^0\) and \(G'^0\) appear and are absorbed by the \(Z\) and \(Z'\) bosons, respectively. It is straightforward to decouple \(G^0\) from the squared mass matrix (2.27) analytically by performing the rotation

\[
\begin{pmatrix} a_d \\ a_u \end{pmatrix} = \begin{pmatrix} \cos \beta & \sin \beta \\ -\sin \beta & \cos \beta \end{pmatrix} \begin{pmatrix} G^0 \\ a \end{pmatrix}, \quad (2.28)
\]
where \( \tan \beta \equiv v_u/v_d \). We diagonalize the reduced \( 11 \times 11 \) matrix \( \tilde{M}_N^2 \) numerically: 
\[
O^T \tilde{M}_N^2 O = \text{diag}(m_{G\alpha}^2, m_1^2, m_2^2, m_3^2, m_4^2, m_5^2, m_6^2, m_7^2, m_8^2, m_9^2),
\]
where \( m_i < m_{i+1} \) (\( i = 1 - 9 \)) and \( O \) is an orthogonal matrix. The explicit expressions for the matrix elements in Eq. (2.27) at the tree level are presented in Appendix A.

A complex \( m_{\tilde{S}_1 \tilde{S}_2}^2 \) and/or a nontrivial \( \varphi_{12} \) can yield nonzero mixing terms between \( \text{CP-even} \) and \( \text{CP-odd} \) Higgs bosons:
\[
\mathcal{M}_{SP}^2 \propto \text{Im}(m_{\tilde{S}_1 \tilde{S}_2}^2 e^{i\varphi_{12}}).
\]

This gives rise to broken \( \text{CP} \) symmetry. A detailed discussion about the \( \text{CP-violating} \) effects on the Higgs masses and couplings will be presented in Subsections 4.1 and 4.2.

In the \( \text{CP-conserving case} \), \( \mathcal{M}_{SP}^2 = \mathbf{0} \) and Eq. (2.27) can be decomposed into two \( 6 \times 6 \) sub-matrices.

Now we consider the one-loop corrections to the Higgs boson masses. It suffices for the current investigation to take into account the contributions of the third-generation quarks \( (t, b) \) and squarks \( (\tilde{t}_{1,2}, \tilde{b}_{1,2}) \). The one-loop effective potential is given by [26]
\[
V_1 = \frac{N_C}{32\pi^2} \sum_{q=t,b} \left[ \sum_{a=1,2} \bar{m}_q^4 \left( \ln \frac{\bar{m}_q^2}{M^2} - \frac{3}{2} \right) - 2\bar{m}_q^4 \left( \ln \frac{\bar{m}_q^2}{M^2} - \frac{3}{2} \right) \right],
\]
which is regularized using the \( \overline{\text{DR}} \)-scheme. Here \( N_C \) denotes the number of colors, \( \bar{m}_q \)’s are the background-field-dependent masses, and \( M \) is the renormalization scale. We determine \( M \) by the condition \( \langle V_1 \rangle = 0 \), which implies
\[
\ln M^2 = \frac{\sum_q [\sum_a \bar{m}_q^4 \ln \frac{m_q^2}{\bar{m}_q^2} - 2m_q^4 \ln m_q^2]}{\sum_q [\sum_a \bar{m}_q^4 - 2m_q^4]} - \frac{3}{2}.
\]

With the one-loop corrections, the tadpole conditions become
\[
0 = \left\langle \frac{\partial V_0}{\partial \phi} \right\rangle + \frac{N_C}{16\pi^2} \sum_{q=t,b} \left[ \sum_{a=1,2} \bar{m}_q^2 \left\langle \frac{\partial \bar{m}_q^2}{\partial \phi} \right\rangle \left( \ln \frac{m_q^2}{\bar{m}_q^2} - 1 \right) - 2m_q^2 \left\langle \frac{\partial \bar{m}_q^2}{\partial \phi} \right\rangle \left( \ln \frac{m_q^2}{\bar{m}_q^2} - 1 \right) \right],
\]
where \( m^2 = \langle \bar{m}^2 \rangle \) and \( \phi \) denotes all species of the Higgs fields. The one-loop corrections of the third-generation quarks and squarks to the Higgs boson masses have exactly the same form as in the NMSSM. The explicit formulas can be found in Ref. [3].

### 2.2 The mass matrix of the charged Higgs bosons

The charged Higgs sector is the same as in the MSSM. Once the \( \mu \) term in the mass formula of the MSSM charged Higgs boson is replaced by the effective \( \mu \) term, \( \mu_{\text{eff}} = \lambda_{\text{S}} \theta \bar{S}/\sqrt{2} \), we can readily obtain the mass of the charged Higgs bosons in the sMSSM. Its squared mass matrix is given by
\[
\begin{pmatrix}
\phi^+_d & \phi^+_u
\end{pmatrix}
\begin{pmatrix}
\mathcal{M}^2_{\pm} & \phi^+_d \\
\phi^-_u & \phi^-_d
\end{pmatrix}
\begin{pmatrix}
\phi^-_d \\
\phi^-_u
\end{pmatrix}.
\]
At the tree level, it follows from Eq. (2.33) that

\[ m_{H^\pm}^2 = m_W^2 + \frac{2R_\lambda v_S}{\sin 2\beta} \frac{\lambda^2}{2} \frac{v^2}{2} + \frac{N_C}{16\pi^2 \sin \beta \cos \beta} \left( \frac{h(m_{t_1}^2)}{(m_{t_1}^2 - m_{b_1}^2)(m_{t_1}^2 - m_{t_2}^2)} + \frac{2m_t^2 R_\lambda v_S}{v^2 \sin^2 \beta} f(m_{t_1}^2, m_{t_2}^2) \right) \]

\[ - \frac{h(m_{b_1}^2)}{(m_{b_1}^2 - m_{t_1}^2)(m_{b_1}^2 - m_{t_2}^2)} + \frac{2m_b^2 R_\lambda v_S}{v^2 \cos^2 \beta} f(m_{b_1}^2, m_{b_2}^2) \]

\[ - \frac{4m_t^2 m_b^2}{v^2 \sin \beta \cos \beta} f(m_t^2, m_b^2) \right) \right], \quad (2.35) \]

Due to the mixing terms between the Higgs doublets and singlets, the relation between the charged Higgs boson mass and the \( CP \)-odd Higgs boson mass, \( m_{H^\pm}^2 = m_W^2 + m_A^2 \), valid in the MSSM, breaks down in general. In the limit of \( \lambda \to 0 \) and \( v_S \to \infty \) with \( \lambda v_S \) being fixed, \( m_{SS_1} = m_{SS_2} = 0 \) and without \( CP \) violation, one of the \( CP \)-odd Higgs boson masses is exactly given by \( 2R_\lambda v_S/\sin 2\beta \). The mass relation in the MSSM is recovered in this particular case.

At the one-loop level, the mass formula of the charged Higgs bosons takes the form [22, 27]

\[ m_{H^\pm}^2 = m_W^2 + \frac{2R_\lambda v_S}{\sin 2\beta} \frac{\lambda^2}{2} \frac{v^2}{2} \]

\[ + \frac{N_C}{16\pi^2 \sin \beta \cos \beta} \left( \frac{h(m_{t_1}^2)}{(m_{t_1}^2 - m_{b_1}^2)(m_{t_1}^2 - m_{t_2}^2)} + \frac{2m_t^2 R_\lambda v_S}{v^2 \sin^2 \beta} f(m_{t_1}^2, m_{t_2}^2) \right) \]

\[ - \frac{h(m_{b_1}^2)}{(m_{b_1}^2 - m_{t_1}^2)(m_{b_1}^2 - m_{t_2}^2)} + \frac{2m_b^2 R_\lambda v_S}{v^2 \cos^2 \beta} f(m_{b_1}^2, m_{b_2}^2) \]

\[ - \frac{4m_t^2 m_b^2}{v^2 \sin \beta \cos \beta} f(m_t^2, m_b^2) \right) \right) \]

where \( R_{t,b} = \text{Re}(\lambda A_{t,b} e^{i\phi_3})/\sqrt{2} \), \( A_{t,b} \) are defined as the trilinear couplings in the soft SUSY breaking sector, and \( f(m_t^2, m_b^2) \) is defined by

\[ f(m_t^2, m_b^2) = \frac{1}{m_1^2 - m_2^2} \left[ m_1^2 \left( \ln \frac{m_1^2}{M^2} - 1 \right) - m_2^2 \left( \ln \frac{m_2^2}{M^2} - 1 \right) \right] . \quad (2.36) \]

The explicit form of \( h(m^2) \) is given in Ref. [27]. As is done in Ref. [3], \( |A_\lambda| \) is determined by Eq. (2.35). Therefore, we take \( m_{H^\pm} \) as an input in our analysis.

3. Allowed region

Finding an acceptable minimum of the Higgs potential is a nontrivial task even at the tree level. Even if we require the tadpole conditions and positive-definiteness of the squared masses of the Higgs bosons, the global minimum can be found at \( v \neq 246 \text{ GeV} \). This is because of the presence of the Higgs singlets in the Higgs potential. In Ref. [7], the following method is adopted to search for the electroweak vacuum. First, the soft SUSY breaking masses and the two trilinear \( A \) terms (\( A_\lambda \) and \( A_{\lambda_S} \)) are taken at arbitrary values. After finding a viable minimum, all the given dimensionful parameters are rescaled so that \( v = 246 \text{ GeV} \). In this method, all the Higgs VEVs are determined through the six tadpole conditions (2.10)-(2.13). Therefore unlike the MSSM, \( \tan \beta \) is an output. Our method is equivalent to that, but the other way around. Explicitly, we take the Higgs VEVs as the inputs, and then perform the minimum search. That is, \( v = 246 \text{ GeV} \) is
In each direction of $R$ function of $\beta$ is obtained: 

$$
\langle V_0 \rangle = \frac{1}{2} m^2 v_d^2 + \frac{1}{2} m^2 v_u^2 + \frac{1}{2} m_S v_S^2 + \sum_i \frac{1}{2} m_i^2 v_i^2,
$$

$$-\text{Re}(m_{SS_1}^2 e^{i\varphi_1})v_S v_{S_1} - \text{Re}(m_{SS_2}^2 e^{i\varphi_2})v_S v_{S_2} - \text{Re}(m_{SS_3}^2 e^{i\varphi_{12}})v_{S_1} v_{S_2},$$

$$-R_\lambda v_d v_u v_S - R_{\lambda_S} v_{S_1} v_{S_2} v_{S_3} + \frac{g^2 + g'^2}{32} (v_d^2 - v_u^2)^2$$

$$+ \frac{|\lambda|^2}{4} (v_d^2 v_u^2 + v_d^2 v_S^2 + v_u^2 v_S^2) + \frac{|\lambda_S|^2}{4} (v_{S_1}^2 v_{S_2}^2 + v_{S_2}^2 v_{S_3}^2 + v_{S_3}^2 v_{S_1}^2) + \frac{g'^2}{8} \Delta^2. \quad (3.1)
$$

In each direction of $v_S = v_{S_1}$ and $v_S = v_{S_2}$ with other VEVs being zero, we demand the coefficients of the quadratic terms be positive so that the effective potential is not unbounded from below:

$$m_S^2 + m_{S_i}^2 - 2 \text{Re}(m_{SS_i}^2 e^{i\varphi_i}) > 0, \quad i = 1, 2. \quad (3.2)
$$

Next we consider the vacuum of the Higgs potential. From the tadpole conditions Eqs. (2.11)-(2.20), the vacuum of the tree-level potential takes the form

$$
\langle V_0 \rangle_{\text{vac}} = \frac{1}{2} R_\lambda v_d v_u v_S + \frac{1}{2} R_{\lambda_S} v_{S_1} v_{S_2} v_{S_3} - \frac{g^2 + g'^2}{32} (v_d^2 - v_u^2)^2$$

$$- \frac{|\lambda|^2}{4} (v_d^2 v_u^2 + v_d^2 v_S^2 + v_u^2 v_S^2) - \frac{|\lambda_S|^2}{4} (v_{S_1}^2 v_{S_2}^2 + v_{S_2}^2 v_{S_3}^2 + v_{S_3}^2 v_{S_1}^2) - \frac{g'^2}{8} \Delta^2. \quad (3.3)
$$

After eliminating $R_\lambda$ with Eq. (2.34) and imposing $\langle V_0 \rangle_{\text{vac}} < 0$, the upper bound on the charged Higgs boson mass is obtained:

$$m_H^2 < m_W^2 + \frac{2|\lambda|^2 v_S^2}{\sin^2 2\beta} + m_Z^2 \cot^2 2\beta - \frac{4R_{\lambda_S}}{v^2 \sin^2 2\beta} v_S v_{S_2} v_{S_3}
$$

$$+ \frac{2|\lambda_S|^2}{v^2 \sin^2 2\beta} (v_{S_1}^2 v_{S_2}^2 + v_{S_2}^2 v_{S_3}^2 + v_{S_3}^2 v_{S_1}^2) + \frac{g'^2}{v^2 \sin^2 2\beta} \Delta^2 \equiv (m_{H^\pm}^\text{max})^2. \quad (3.4)
$$

As an example, we plot the maximal value of the charged Higgs boson mass as a function of $R_{\lambda_S}$ in Fig. 4. We take $\lambda = -0.8, \lambda_S = 0.1, v_S = 300 \text{ GeV}, v_{S_1} = v_{S_2} = v_{S_3} = 3000 \text{ GeV}$, and $\tan \beta = 1$ (red solid line), 5 (green dotted line), 10 (blue dashed line). The $CP$-violating phases are assumed to be zero. Since the dominant terms are proportional to $1/\sin^2 2\beta$ in $m_{H^\pm}^\text{max}$, $\tan \beta = 1$ gives the smallest $m_{H^\pm}^\text{max}$ for a fixed $R_{\lambda_S}$. For $R_{\lambda_S} > 0$, the value of $m_{H^\pm}^\text{max}$ decreases as $R_{\lambda_S}$ increases. We find a maximum of $R_{\lambda_S} \simeq 640 \text{ GeV}$. 

---

9
Figure 1: The maximum of charged Higgs boson mass as a function of \( R_{\lambda S} \). We take \( v_S = 300 \) GeV, \( v_{S_1} = v_{S_2} = v_{S_3} = 3000 \) GeV, and \( \tan \beta = 1 \) (red solid line), 5 (green dotted line), 10 (blue dashed line).

3.2 Experimental constraints

The \( U(1)' \) charges of the Higgs fields can be constrained by the experimental results of the \( Z' \) boson search, namely, the lower bound on the \( Z' \) boson mass and the upper bound on the mixing angle between the \( Z \) and \( Z' \) bosons. The squared mass matrix of the \( Z \) and \( Z' \) bosons takes the form

\[
\mathcal{M}_{ZZ'}^2 = \begin{pmatrix}
m_Z^2 & m_Z g_1' (Q_H Q_H^c \cos^2 \beta - Q_H Q_H^c \sin^2 \beta) v \\
m_Z g_1' (Q_H Q_H^c \cos^2 \beta - Q_H Q_H^c \sin^2 \beta) v & m_{Z'}^2
\end{pmatrix},
\]

where

\[
m_Z^2 = \frac{g_2^2 + g_1^2}{4} v^2, \tag{3.6}
\]

\[
m_{Z'}^2 = g_1'^2 \left( Q_{H_H}^2 v_d^2 + Q_{H_H}^2 v_u^2 + Q_S^2 v_S^2 + \sum_i Q_{i_S}^2 v_{i_S}^2 \right). \tag{3.7}
\]

The eigenvalues of the squared mass matrix and the mixing angle between the \( Z \) and \( Z' \) bosons are respectively given by

\[
m_{Z,1,2}^2 = \frac{1}{2} \left[ m_Z^2 + m_{Z'}^2 \pm \sqrt{(m_Z^2 - m_{Z'}^2)^2 + g_1'^2 (g_2^2 + g_1^2)(Q_H Q_H^c v_d^2 - Q_H Q_H^c v_u^2)^2} \right], \tag{3.8}
\]

\[
\alpha_{ZZ'} = \arctan \left( \frac{2m_Z g_1' (Q_H Q_H^c \cos^2 \beta - Q_H Q_H^c \sin^2 \beta) v}{m_{Z'}^2 - m_Z^2} \right). \tag{3.9}
\]

The experimental constraints on the \( Z' \) boson are rather model-dependent. Here we adopt the typical bounds, \( m_{Z'} > 600 \) GeV and \( \alpha_{ZZ'} < O(10^{-3}) \) [14]. In Figs. 2, we plot the \( m_{Z'} = 600 \) GeV contour and curves for \( \alpha_{ZZ'} = (1, 3, 5) \times 10^{-3} \) in the \( Q_{H_H} Q_{H_H}^c \) plane. The other \( U(1)' \) charges are determined by the gauge invariance and the condition for
breaking the two unwanted global $U(1)$ symmetries as discussed above. Here we show two examples: (A) $v_S = 300$ GeV, $v_{S_1} = v_{S_2} = v_{S_3} = 3000$ GeV with $\tan \beta = 1$ (upper left figure) and $\tan \beta = 50$ (upper right figure); (B) $v_S = 500$ GeV, $v_{S_1} = v_{S_2} = 100$ GeV, $v_{S_2} = 3000$ GeV with $\tan \beta = 1$ (lower left figure) and $\tan \beta = 10$ (lower right figure). The red dotted lines give the $m_{Z'} \leq 600$ GeV contour, and the region in between represents $m_{Z'} \leq 600$ GeV. The figures also show curves for $\alpha_{ZZ} = 1 \times 10^{-3}$ (dashed line in green), $\alpha_{ZZ} = 3 \times 10^{-3}$ (dotted line in blue) and $\alpha_{ZZ} = 5 \times 10^{-3}$ (solid line in magenta). In the region where $Q_{H_d}$ and $Q_{H_u}$ have the same sign, the two terms in the off-diagonal elements of $\mathcal{M}_{ZZ'}^2$ tend to cancel with each other. The upper right figures show that the $\tan \beta$ dependence on $Z'$ search constraints is rather mild since the denominator in Eq. (3.9) is relatively large for case (A). In the lower left figure, the covered areas of quadrants II and IX have $\alpha_{ZZ} > 1 \times 10^{-3}$. On the other hand, large portions of quadrants I and III are not strongly constrained. If we take $\tan \beta = 10$, the contours of $\alpha_{ZZ}$ is distorted and the region around $Q_{H_d} \simeq -Q_{H_u} / \tan^2 \beta$ becomes allowed. In our numerical study, as long as one of $v_{S_i}$ ($i = 1 - 3$) is taken to be at the TeV scale and $Q_{H_d} \simeq -Q_{H_u}$ does not hold, the constraints from the $Z'$ boson search can be easily avoided. This supports the original motivation for the sMSSM as mentioned in the Introduction.

According to the LEP experiments, the mass of the SM Higgs boson should be larger than 114.4 GeV at 95 % CL [14]. However, this lower bound cannot be directly applied to models beyond the SM due to the modification of the Higgs coupling to the $Z$ boson ($g_{HHZZ}$). When the Higgs boson masses are smaller than 114.4 GeV, we require instead

$$\xi^2 < k(m_{H_i}) \ , \quad (3.10)$$

where $\xi = g_{HHZZ}/g_{SMHZZ}$ and $k$ is the 95 % CL upper limit on the $HZZ$ coupling and a function of the Higgs boson mass [23, 24]. In our analysis, we do not consider the processes $e^+e^- \rightarrow Z^* \rightarrow H_iH_j$. They are expected to be less severe in comparison with the processes $e^+e^- \rightarrow Z^* \rightarrow H_iZ$.

We also consider the $Z$ boson decays, $Z \rightarrow H_iH_j$ and $Z \rightarrow H_il^+l^-$ for the light Higgs bosons, and require that:

$$\sum_{i,j} \Gamma(Z \rightarrow H_iH_j) + \sum_i \Gamma(Z \rightarrow H_il^+l^-) < \Delta \Gamma_Z \ , \quad (3.11)$$

where $\Delta \Gamma_Z = 2.0$ MeV is the 95 % CL upper bound on the possible additional decay width of the $Z$ boson [23].

The other experimental constraints come from the lower bounds of the SUSY particles. The mass matrix of the charginos has the same form as in the MSSM if we replace $\mu$ with $\mu_{eff}$:

$$\mathcal{M}_{\tilde{\chi}} = \left( \begin{array}{cc} M_2 & -\sqrt{2}m_W \cos \beta \\ -\sqrt{2}m_W \sin \beta & \mu_{eff} e^{i(\theta_1 + \theta_2)} \end{array} \right) , \quad (3.12)$$

where $M_2$ is the $SU(2)$ gaugino mass. The physical $CP$-violating phase is $\theta_{M_2} + \theta_\lambda + \varphi_3$, where $\theta_{M_2}$ and $\theta_\lambda$ denote the arguments of $M_2$ and $\lambda$, respectively. For the lower bound
on the lightest chargino mass \( \tilde{\chi}^\pm_1 \), we require \( m_{\tilde{\chi}^\pm_1} > \sqrt{s}/2 \approx 104 \text{ GeV} \), where \( \sqrt{s} \) is the center-of-mass energy at LEP2 [31]. On the other hand, the mass bound on the neutralino, \( m_{\tilde{\chi}^0} > 46 \text{ GeV} \) given in Ref. [14] is rather model-dependent. In fact, it is found that \( m_{\tilde{\chi}^0} \approx 6 \text{ GeV} \) is allowed in the R-parity conserving MSSM without gaugino mass unification [32]. In the sMSSM, the lightest neutralino can even be massless, almost a singlino [33]. Therefore we will not put an explicit lower bound on the mass of the lightest neutralino, and not require that the lightest neutralino be a candidate for the cold dark matter of the Universe as well.

Now we consider extra contributions to the \( \rho \) parameter. It can be easily shown that if a model has only Higgs doublets and singlets, \( \rho = 1 \) at the tree level. As discussed before, as long as \( \alpha_{ZZ'} < \mathcal{O}(10^{-3}) \), the deviation of the \( \rho \) parameter from unity due to the
The $Z'$ boson is small enough to evade the current experimental bound $\Delta \rho < 2.0 \times 10^{-3}$ \cite{footnote2}. Let us consider the one-loop corrections, focusing particularly on the contributions of the physical Higgs bosons rather than including all SUSY particles. The correction to the $\rho$ parameter is given by

$$\Delta \rho = \frac{\Pi_{VZ}^T(0)}{m_Z^2} - \frac{\Pi_{WW}^T(0)}{m_W^2},$$

(3.13)

where $\Pi_{VV}^T(0)$ ($V = Z, W$) are the transverse parts of the weak boson self-energies at the zero momentum. The Higgs boson contributions at the one-loop level take the form

$$\Delta \rho^{\text{Higgs}} = \frac{G_F}{8\sqrt{2}\pi^2} \left[ \sum_{i<j}^2 g_{H_iH_jZ}^2 B_5(m_{H_i}, m_{H_j}) - \sum_i |g_{H_iHW}|^2 B_5(m_{H^\pm}, m_{H_i}) \right],$$

(3.14)

with

$$B_5(m_1, m_2) = \begin{cases} \frac{1}{2}(m_1^2 + m_2^2) + \frac{m_1^2 m_2^2}{m_1^2 - m_2^2} \ln \frac{m_1^2}{m_2^2} (m_1 \neq m_2), \\ 0 (m_1 = m_2) \end{cases},$$

(3.15)

$$g_{H_iH_jZ} = (O_{1i} O_{1j} - O_{1j} O_{1i}) \sin \beta - (O_{2i} O_{2j} - O_{2j} O_{2i}) \cos \beta,$$

(3.16)

$$g_{H_iHW} = O_{2i} \cos \beta - O_{1i} \sin \beta - iO_{1i},$$

(3.17)

where $G_F = 1/(\sqrt{2}v^2) \simeq 1.166 \times 10^{-5}$ (GeV)$^{-2}$. Unlike the MSSM, the custodial $SU(2)$ symmetry does not guarantee $\Delta \rho^{\text{Higgs}} = 0$ due to the contributions from the Higgs singlets.

Finally we comment in passing on the constraints from $B$ physics. The experimental results of $B_s \rightarrow \mu^+\mu^-$, $b \rightarrow s\gamma$ and $B_u^- \rightarrow \tau^-\nu_\tau$ can give a significant restriction on the parameter space. However, so long as we limit our interest to the low tan $\beta$ region ($\lesssim 20$), constraints from the branching ratios of $B_s \rightarrow \mu^+\mu^-$ and $B_u^- \rightarrow \tau^-\nu_\tau$ are less stringent. The $b \rightarrow s\gamma$ process can be important for the light charged Higgs bosons scenario, $m_{H^\pm} \lesssim 300$ GeV, in which case the contributions from the charged Higgs bosons and those of the charginos have to cancel \cite{footnote2} in a way to be consistent with the data \cite{footnote3}. We leave the detailed analysis to another paper.

### 3.3 Numerical evaluation

Now we show the numerical results of the allowed regions in both case I and case II. We take

$$Q_{H_d} = Q_{H_u} = 1, \quad A_{\lambda_S} = A_\lambda(m_{H^\pm}), \quad A_t = A_b = \mu_{\text{eff}}/\tan \beta, \quad m_{\tilde{q}} = 1000 \text{ GeV}, \quad m_{\tilde{t}_R} = m_{\tilde{b}_R} = 500 \text{ GeV}, \quad M_2 = 200 \text{ GeV},$$

(3.18)

where $m_{\tilde{q}}$, $m_{\tilde{t}_R}$ and $m_{\tilde{b}_R}$ are the soft SUSY breaking masses of squarks. It should be noted that $A_\lambda$ is a function of $m_{H^\pm}$, as given by Eq. (2.35). In Fig. 3 the allowed region is plotted in the $\lambda_S$-$\lambda$ plane (left figure) and $\tan \beta$-$m_{H^\pm}$ plane (right figure). The input parameters in Case I are

Case I: $m_{\tilde{S}_1}^2 = m_{\tilde{S}_2}^2 = (500 \text{ GeV})^2$, $m_{\tilde{S}_1}^2 m_{\tilde{S}_2} = -(50 \text{ GeV})^2$, $v_S = 300 \text{ GeV}$, $v_{S_1} = v_{S_2} = v_{S_3} = 3000 \text{ GeV}.$

(3.19)
\begin{align*}
\tan\beta &= 1, \quad m_H = 300 \text{ GeV} \\
\theta_{\text{phys}} &= 0 \\
\text{Unstable Vacuum} \\
\lambda_S &\quad 0.1 \\
\text{Allowed Region} \\
\text{Metastable Vacuum} \\
\text{Unstable Vacuum} \\
\lambda &\quad -1, -0.9, -0.8, -0.7, -0.6, -0.5, -0.4, -0.3, -0.2, -0.1 \\
\lambda_S &\quad 0.1 \\
\text{Excluded by LEP} \\
\end{align*}

\begin{align*}
\lambda &= -0.8, \quad \lambda_S = 0.1 \\
\theta_{\text{phys}} &= 0 \\
\text{Unstable Vacuum} \\
\text{Allowed Region} \\
\text{Metastable Vacuum} \\
\text{Unstable Vacuum} \\
\tan\beta &\quad 1 \\
m_{H^\pm} &\quad (0 \text{ GeV}) \\
\end{align*}

Figure 3: The allowed region in the $\lambda_S$-$\lambda$ plane (left figure) and $\tan\beta$-$m_{H^\pm}$ plane (right figure). We take $Q_{H_d} = Q_{H_u} = 1$, $m^2_{SS_1} = m^2_{SS_2} = (500 \text{ GeV})^2$, $m^2_{S_1S_2} = -(50 \text{ GeV})^2$, $v_S = 300 \text{ GeV}$, $v_{S_1} = v_{S_2} = v_{S_3} = 3000 \text{ GeV}$.

For the moment, all the $CP$-violating phases are assumed to be zero. In the left figure, we take $\tan\beta = 1$ and $m_{H^\pm} = 300 \text{ GeV}$. All the Higgs boson masses are non-negative in the region between the two blue curves. For fixed $\lambda$, the depth of the vacuum decreases as $\lambda_S$ decreases and eventually becomes higher than the origin, as can be seen from Eq. (3.3). The dotted curve in magenta corresponds to the critical situation, below which the vacuum becomes metastable. The region to the right of the dotted-dashed line in green has been excluded by the condition (3.10). Likewise, the region to the right of the dashed line in red is excluded by the chargino lower mass bound. In the right figure, we take $\lambda = -0.8$, $\lambda_S = 0.1$. As in the left figure, $m^2_H \geq 0$ is fulfilled between the two blue curves, within which the vacuum becomes metastable below the dotted curve in magenta. The region below the dotted-dashed curve in green is excluded by the condition (3.10), and that below the dashed curve in black by $\Delta\rho > 2.0 \times 10^{-3}$. Since the Higgs singlets can affect the lightest Higgs boson mass, the possibility $\tan\beta = 1$ excluded in the MSSM is experimentally allowed in our model. On the contrary, the allowed region is much more restricted by the conditions for the desired electroweak vacuum.

In Fig. 4, we consider

Case II: $m^2_{SS_1} = (306 \text{ GeV})^2$, $m^2_{SS_2} = (56 \text{ GeV})^2$, $m^2_{S_1S_2} = (100 \text{ GeV})^2$, $v_S = 500 \text{ GeV}$, $v_{S_1} = v_{S_3} = 100 \text{ GeV}$, $v_{S_2} = 3000 \text{ GeV}$. \hfill (3.20)

In the left figure, we use $\tan\beta = 1$ and $m_{H^\pm} = 600 \text{ GeV}$. The region to the left of the blue line is excluded by $m^2_H < 0$, and that above the dashed curve in blue results in the situation where $V = V_0 + V_1$ is unbounded from below. In the region between the two lines in magenta, the vacuum is correctly located at $v = 246 \text{ GeV}$. However, the region to the left of the dotted-dashed line in green is excluded by Eq. (3.10). The fact that
Figure 4: The allowed region in the $\lambda_S$-$\lambda$ plane (left figure) and $\tan \beta$-$m_{H^\pm}$ plane (right figure). We take $Q_{H_u} = Q_{H_d} = 1$, $m_{S_1}^2 = (306 \text{ GeV})^2$, $m_{S_2}^2 = (56 \text{ GeV})^2$, $m_{S_1S_2}^2 = (100 \text{ GeV})^2$, $v_S = 500$ GeV, $v_{S_1} = v_{S_2} = 100$ GeV and $v_{S_3} = 3000$ GeV.

$m_{H^\pm}$ in this case is larger than Case I implies that $R_\lambda$ is larger. A small $\lambda$ can make the vacuum metastable, as can be seen from Eq. (3.3). In the right figure, we take $\lambda = 0.8$ and $\lambda_S = 0.1$. The allowed region is inside the two dotted-dashed curves in green and the two dashed lines in orange. The dotted-dashed curves in green are obtained from the critical value of the LEP bound (3.10) explained above. The dashed lines in orange correspond to $\alpha_{ZZ'} = 1 \times 10^{-3}$. The parameter space is highly constrained in Case II.

4. CP violation

In this section, we study the effects of CP violation in the Higgs sector. In the MSSM, the CP-violating phase in the Higgs potential can be rotated away by a field redefinition. Hence there is no explicit CP violation at the tree level. However, once the one-loop corrections from the squark sector to the Higgs boson masses are taken into account, mixing terms between the CP-even and CP-odd Higgs bosons are generated. In a specific CP-violating case called the CPX scenario, the effects of CP violation is extremely enhanced, and the Higgs phenomenology is drastically changed [21, 22, 23]. The lightest Higgs boson mass, for example, can become much smaller than the current LEP lower bound due to the large $\mathcal{M}_{SP}^2$ in the squared mass matrix. Its coupling to the $Z$ boson, however, can be sufficiently suppressed to escape from the LEP constraints [24]. Studies of ECPV have been done in the NMSSM [3, 36, 37], nMSSM [5] and the UMSSM [38, 39] as well. Here we discuss both ECPV and SCPV in the sMSSM.

4.1 Explicit CP violation

As discussed in Section 3, there is one CP-violating phase that cannot be removed by rephasing the Higgs fields. In fact, the nonzero CP-violating phases are related to each
other in the vacuum through the tadpole conditions for the CP-odd Higgs fields. At the one-loop level, we find

\[ I_\lambda = -\frac{N_C}{8\pi^2 v^2} \left[ \frac{m^2}{\sin^2\beta} f(m^2_{h_1^+}, m^2_{h_2^+}) + \frac{m_b^2}{\cos^2\beta} f(m^2_{h_1^0}, m^2_{h_2^0}) \right], \quad \text{(4.1)} \]

\[ I_{\lambda_S} = 0, \quad \text{(4.2)} \]

\[ \text{Im}(m_{SS_1}^2 e^{i\varphi_1}) = \text{Im}(m_{SS_1}^2 m_{S_2}^2 e^{i\varphi_{12}}) \frac{v_{S_2}}{v}, \quad \text{(4.3)} \]

\[ \text{Im}(m_{SS_2}^2 e^{i\varphi_2}) = -\text{Im}(m_{SS_1}^2 m_{S_2}^2 e^{i\varphi_{12}}) \frac{v_{S_1}}{v}, \quad \text{(4.4)} \]

where \( I_{t,b} = \text{Im}(\lambda A_t b e^{i\varphi_1})/\sqrt{2} \). If \( I_t \) or \( I_b \) is nonzero, \( I_\lambda \) can be nonzero as well at the one-loop level. Nevertheless, we will focus exclusively on CP violation peculiar to the sMSSM, and take \( I_t = I_b = 0 \) in what follows. Since we have the relation Eq. (2.35), the sign of \( R_{\lambda} \) is determined through

\[ \text{sgn}(R_{\lambda}) = \text{sgn} \left( m_{H^\pm}^2 - m_{W^0}^2 + \frac{|\lambda|^2}{2} v^2 - \Delta m_{H^\pm}^2 \right), \quad \text{(4.5)} \]

where \( \Delta m_{H^\pm}^2 \) denotes the one-loop correction to the charged Higgs boson mass. On the contrary, there is a sign ambiguity in \( R_{\lambda_S} \) at this stage. The positivity of the squared mass of the Higgs bosons gives us \( R_{\lambda_S} > 0 \) in most of the parameter space. Now let us define

\[ \theta_{SS_1} = \text{Arg}(m_{SS_1}^2), \quad \theta_{SS_2} = \text{Arg}(m_{SS_2}^2), \quad \theta_{S_1 S_2} = \text{Arg}(m_{S_1 S_2}^2). \]

From Eqs. (4.3) and (4.4), it follows that

\[ \theta_{SS_1} = \sin^{-1} \left[ \frac{m_{S_1 S_2}^2}{m_{SS_1}^2} \frac{v_{S_2}}{v} \sin(\theta_{S_1 S_2} + \varphi_{12}) \right] - \varphi_1, \quad \text{(4.6)} \]

\[ \theta_{SS_2} = \sin^{-1} \left[ - \frac{m_{S_1 S_2}^2}{m_{SS_2}^2} \frac{v_{S_1}}{v} \sin(\theta_{S_1 S_2} + \varphi_{12}) \right] - \varphi_2. \quad \text{(4.7)} \]

It should be noted that the arguments in the arcsines should be smaller than one, imposing additional constraints on our input parameters.

The CP-violating phases show up in the mixing terms between CP-even and CP-odd parts in the squared mass matrix (3.27). Let us parameterize \( \mathcal{M}_{SP}^2 \) in terms of 3 \( \times \) 3 block entries:

\[ \frac{1}{2} \left( h_O^T \ h_S^T \right) \mathcal{M}_{SP}^2 \left( \begin{array}{c} a_O \\ a_S \end{array} \right), \quad \mathcal{M}_{SP}^2 = \left( \begin{array}{c} \mathcal{M}_{SP}^{(O)} \\ \mathcal{M}_{SP}^{(OS)} \end{array} \right) \left( \begin{array}{c} \mathcal{M}_{SP}^{(OS)}^T \\ \mathcal{M}_{SP}^{(S)} \end{array} \right). \quad \text{(4.8)} \]

After the conditions (4.3) and (4.4) are applied, the entries are

\[ \mathcal{M}_{SP}^{(O)} = 0_{3 \times 3}, \quad \mathcal{M}_{SP}^{(OS)} = \text{Im}(m_{S_1 S_2}^2 e^{i\varphi_{12}}) \left( \begin{array}{ccc} 0 & 0 & 0 \\ 0 & 0 & 0 \\ \frac{v_{S_2}}{v} - \frac{v_{S_1}}{v} & 0 \end{array} \right), \quad \text{(4.9)} \]

\[ \mathcal{M}_{SP}^{(S)} = \text{Im}(m_{S_1 S_2}^2 e^{i\varphi_{12}}) \left( \begin{array}{ccc} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{array} \right). \quad \text{(4.10)} \]
Figure 5: The effects of the CP-violating phase on $m_H$ and $g_{HVV}^2$. We take $m_{H^\pm} = 600$ GeV, \(\tan \beta = 1\), \(|m_{S_1}^2| = (306 \text{ GeV})^2\), \(|m_{S_2}^2| = (56 \text{ GeV})^2\), \(|m_{S_1 S_2}^2| = (100 \text{ GeV})^2\), $v_S = 500$ GeV, $v_{S_1} = v_{S_3} = 100$ GeV, and $v_{S_2} = 3000$ GeV.

If $M_{SP}^2$ has a large portion in $M_N^2$, the CP-violating effects on the Higgs boson masses can be enhanced. To achieve this, we assume large values for Im($m_{S_1 S_2}^2 e^{i\varphi_{12}}$)$v_{S_2}/v_S$ and Im($m_{S_1 S_2}^2 e^{i\varphi_{12}}$)$v_{S_1}/v_S$ under the conditions (4.6) and (4.7), rendering

$$|m_{S_1}^2| \simeq |m_{S_1 S_2}^2| \frac{v_{S_2}}{v_S},$$

(4.11)

$$|m_{S_2}^2| \simeq |m_{S_1 S_2}^2| \frac{v_{S_1}}{v_S},$$

(4.12)

for $\sin(\theta_{S_1 S_2} + \varphi_{12}) \simeq 1$. For the moment, we only consider ECPV, and hence $\varphi_1 = \varphi_2 = 0$. We present two examples: one being Case II as given in Eq. (3.20) and the other being Case III specified by

Case III: $m_{S_1}^2 = (72 \text{ GeV})^2$, $m_{S_2}^2 = (280 \text{ GeV})^2$, $m_{S_1 S_2}^2 = (100 \text{ GeV})^2$, $v_S = 300$ GeV, $v_{S_1} = v_{S_3} = 1500$ GeV, $v_{S_2} = 100$ GeV.

(4.13)

We take $\tan \beta = 1$ and $m_{H^\pm} = 600$ GeV for Case II and $\tan \beta = 1$ and $m_{H^\pm} = 300$ GeV for Case III. In Fig. 5, we plot $m_{H_i}$ and $g_{H_iVV}^2$ ($i = 1 - 3$) as functions of $\theta_{S_1 S_2}$ in Case II. In the CP-conserving case, $\theta_{S_1 S_2} = 0$, the second lightest Higgs boson is CP-odd because $g_{H_2VV}$ is zero. Around $\theta_{S_1 S_2} \simeq 40^\circ$, $H_1$ and $H_2$ switch with each other and their CP characters are exchanged, as can be seen from the right figure in Fig. 5. As in the CP-violating MSSM, due to the large off-diagonal terms $M_{SP}^2$, $H_1$ can become lighter than 114.4 GeV for $\theta_{S_1 S_2} \gtrsim 60^\circ$ with $g_{H_1VV}^2$ being highly suppressed. This possibility cannot be excluded by the LEP experimental results. This does not seem to be typical in the CP-violating NMSSM \[3\]. Although all the Higgs boson masses are positive in the range $93^\circ \lesssim \theta_{S_1 S_2} \lesssim 102^\circ$, the vacuum is metastable and is thus excluded. In Fig. 6, we plot $m_{H_i}$ and $g_{H_iVV}^2$ ($i = 1 - 3$) as functions of $\theta_{S_1 S_2}$ for Case III. When $\theta_{S_1 S_2} = 0$, $H_1$ is the
The effects of the CP-violating phase on $m_H$ and $g_{HVV}^2$. We take $m_{H\pm} = 300$ GeV, $\tan \beta = 1$, $|m_{S_{1S}1}| = (72$ GeV$)^2$, $|m_{S_{2S}2}| = (280$ GeV$)^2$, $|m_{S_{1S}2}| = (100$ GeV$)^2$, $v_S = 300$ GeV, $v_{S_1} = v_{S_3} = 1500$ GeV, and $v_{S_2} = 100$ GeV.

$CP$-odd Higgs boson since $g_{H_1VV} = 0$. In this parameter set, $H_3$ is the SM-like Higgs boson, corresponding to the decoupling limit in the MSSM. Both $H_1$ and $H_2$ are composed of almost singlet components. The mass $m_{H_1}$ is always smaller than the LEP bound when we vary $\theta_{S_1S_2}$, and can become as low as 20 GeV around $\theta_{S_1S_2} = 102^\circ$. Since $g_{H_1VV}^2$ is less than $10^{-3}$, the associated production cross section of $H_1$ with gauge bosons is highly suppressed. The masses and couplings of the other Higgs bosons are not much affected by $CP$ violation.

### 4.2 Spontaneous $CP$ violation

In this subsection, we discuss the SCPV scenario. If the model contains two Higgs doublets, one of the Higgs VEVs can be complex in principle. In the MSSM, there is no room for the relative phase between the two Higgs doublets in the potential in the SUSY limit due to $U(1)_{PQ}$. The only place where the relative phase can show up is the quadratic mixing term between the two Higgs doublets to break the SUSY softly. After imposing the tadpole conditions, such a phase disappears. It is found that the one-loop corrections to the Higgs potential can induce radiative SCPV [40]. However, it leads to the appearance of a light pseudoscalar ($m_A \lesssim 6$ GeV), which is already excluded by the LEP experiments. Many studies have already been done for SCPV in the NMSSM with a $Z_3$ symmetry [41, 42, 43, 44]. According to Romão’s No-Go theorem [42], with certain radiative corrections in the Higgs sector the condition for SCPV leads to a negative squared-mass mode in the Higgs spectrum. However, it is pointed out by Babu and Barr [43] that the large radiative corrections from the top/stop loops have not been taken into account in the proof of the No-Go theorem. The original saddle point in the Higgs potential can become a minimum in this case and, therefore, the tachyonic mode no longer appears. In Ref. [44], the upper bound on the lightest Higgs boson mass is found to be about 140 GeV in the case of SCPV.
where the full one-loop corrections of top/stop have been included in their calculations. In the NMSSM without a $Z_3$ symmetry, the No-Go theorem cannot be applied any more. Hence, the SCPV scenario is viable even at the tree level [15].

In the sMSSM, SCPV is induced by the nonzero $\theta$’s that appear in the quadratic terms of the Higgs potential. This is also free from the No-Go theorem. To simplify our study, we assume that $m_{SS1}^2$, $m_{SS2}^2$, $\lambda A_{S}$ and $\lambda A_{S}A_{S}$ are all real. From the tadpole conditions (4.1)-(4.4), we find

\begin{align}
& a \sin \varphi_1 + b \sin \varphi_2 = 0, \\
& a \cos \varphi_1 + b \cos \varphi_2 = -\frac{ab}{c}, \\
& \varphi_3 = \varphi_4 = 0,
\end{align}

(4.14) (4.15) (4.16)

where $a = m_{SS1}^2 v_S v_S$, $b = m_{SS2}^2 v_S v_S$, and $c = m_{S1S2}^2 v_S v_S$. When Eqs. (4.14) and (4.15) have solutions, they form a triangle as depicted in Fig. [7]. The analytic solutions can be easily obtained:

\begin{align}
& \cos \varphi_1 = \frac{1}{2} \left( \frac{bc}{a^2} - \frac{c}{b} - \frac{b}{c} \right), \\
& \cos \varphi_2 = \frac{1}{2} \left( \frac{ac}{b^2} - \frac{a}{c} - \frac{c}{a} \right), \\
& \cos(\varphi_1 - \varphi_2) = \frac{1}{2} \left( \frac{ab}{c^2} - \frac{b}{a} - \frac{a}{b} \right),
\end{align}

(4.17) (4.18) (4.19)

which give the $CP$-violating extremum. The Higgs potential has the $CP$-violating minimum when $ac/b < 0$.

We can set $\theta_1 = \theta_{S_2} = 0$ without loss of generality in Eq. (2.3). Since $\varphi_3 = \varphi_4 = 0$, it follows that

\begin{align}
& \theta_2 = -\frac{1}{2}(\varphi_1 + \varphi_2), \\
& \theta_S = \frac{1}{2}(\varphi_1 + \varphi_2), \\
& \theta_{S_1} = \frac{1}{2}(\varphi_1 - \varphi_2), \\
& \theta_{S_2} = -\frac{1}{2}(\varphi_1 - \varphi_2).
\end{align}

(4.20) (4.21)

We examine the possible maximal value of $m_H$ in the case of SCPV. Since the numerical minimum search is rather time-consuming, we do not conduct a complete parameter scan. Instead, we restrict ourselves to scan only the three soft SUSY breaking masses in the
The left plot shows the upper bounds on the four light neutral Higgs boson masses, $m_{H_1}^{\text{max}}$ (cross in red), $m_{H_2}^{\text{max}}$ (triangle in green), $m_{H_1}^{\text{max}}$ (circle in blue) and $m_{H_1}^{\text{max}}$ (square in yellow), as functions of $m_{H^\pm}$. The right plot shows $|\sin \varphi_1|$ and $|\sin \varphi_2|$. The crosses in red are for $|\sin \varphi_1|$, and the triangles in green for $|\sin \varphi_2|$.

Following ranges:

\[ m_{SS_1}^2 = m_{SS_2}^2 = (10 \text{ GeV})^2 - (1000 \text{ GeV})^2, \]
\[ -m_{S_1S_2}^2 = (1000 \text{ GeV})^2 - (10 \text{ GeV})^2, \]  

(4.22)

for fixed values of $m_{H^\pm}$. The remaining parameters are chosen as $\lambda = -0.8$, $\lambda_S = 0.1$, $\tan \beta = 1$, $v_S = 300 \text{ GeV}$, and $v_{S_1} = v_{S_2} = v_{S_3} = 3000 \text{ GeV}$. In Fig. 8, the maximal values of $m_{H_i}$ ($i = 1 - 4$) (left figure) and $|\sin \varphi_1|$ and $|\sin \varphi_2|$ (right figure) are plotted as functions of $m_{H^\pm}$. For each fixed $m_{H^\pm}$, all $m_{H_i}^{\text{max}}$ are obtained for different sets of $(m_{SS_1}, m_{SS_2}, m_{S_1S_2})$. One can see that the upper bounds on $m_{H_i}$ strongly depend on $m_{H^\pm}$ except for $m_{H_2}$. It is found that the upper bound on the lightest neutral Higgs boson mass $m_{H_1}^{\text{max}}$ is below 125 GeV and can reach up to around 123 GeV for $m_{H^\pm} = 334 \text{ GeV}$. Since the lightest state $H_1$ is mainly composed of the singlet states, $m_{H_1}$ do not increase even if we change the values of $(m_{\tilde{q}}, m_{\tilde{t}_R}, m_{\tilde{b}_R})=(1000, 500, 500) \text{ GeV}$ into, say $(3000, 1500, 1500) \text{ GeV}$. In this case, the second lightest Higgs boson $H_2$ receives corrections from the top/stop loops. From the right figure of Fig. 8, one can see that the CP symmetry is maximally violated when $m_{H_1}^{\text{max}} > 100 \text{ GeV}$.

It is noticed that the CP-violating solutions $\varphi_1$ and $\varphi_2$ are obtained by solving the necessary conditions for SCPV, Eqs. (4.14) and (4.15). In order to check whether they give CP violation at the vacuum, we perform the minimization in the ten-dimensional parameter space $(v_d, v_u, v_S, v_{S_1}, v_{S_2}, v_{S_3}, \theta_2, \theta_S, \theta_{S_1}, \theta_{S_2})$, and find that the solutions obtained above indeed give the CP-violating vacuum.

4.3 EDM constraints

The CP-violating phases can also be constrained by the upper bounds on electric dipole
moments (EDMs) of electron, neutron and mercury atom \[16, 17\]. Similar to the MSSM, the SUSY particles-mediated one-loop diagrams contribute to the EDMs. However, we assume that the only sources of $CP$ violation come from $\theta_{S_1S_2}$ for ECPV and $\varphi_i$ ($i = 1, 2$) for SCPV in the sMSSM. Therefore, their contributions to the EDMs generally vanish. At the two-loop level, however, the Higgs bosons with indefinite $CP$ properties can contribute to the so-called Barr-Zee type diagrams \[17\] and become sizable when $\tan \beta$ is large. Since we take $\tan \beta = 1$ in the $CP$-violating cases, we expect that they do not put severe constraints on $\theta_{S_1S_2}$ or $\varphi_i$ ($i = 1, 2$).

5. Conclusions

We have studied the Higgs sector of the sMSSM with particular focus on $CP$ violation. The masses and couplings of the Higgs bosons are calculated using the one-loop effective potential, including corrections due to the third-generation quarks and squarks. Imposing both the theoretical and experimental constraints, the allowed region is obtained for Case I and Case II defined in the text. In short, all Higgs VEVs of the secluded Higgs singlets in Case I are taken to be of $O(\text{TeV})$, and in Case II two of them are of $O(100 \text{ GeV})$ and the other of $O(\text{TeV})$. Due to the corrections from the Higgs singlets, the $\tan \beta = 1$ case cannot be ruled out by the LEP experimental results. However, the conditions for the desired electroweak vacuum generally render a very restrictive parameter space.

In this model, ECPV can be induced by the nonzero phase of $m_{S_1S_2}^2$ at the tree level. It is found that a large value of $\theta_{S_1S_2}$ can make the lightest Higgs boson lighter than the LEP bound of 114.4 GeV, provided that the Higgs coupling to the $Z$ boson is sufficiently suppressed, similar to the CPX scenario in the MSSM. Nevertheless, large $\mu$ and $A$ terms are not required in the sMSSM for the realization of large $CP$ violation. Therefore, the spectrum of SUSY particles is generally different from the MSSM CPX scenario.

We have also investigated the SCPV scenario. Unlike the MSSM, SCPV can occur at the tree level in the presence of the nonzero $\theta$‘s residing in the quadratic terms of the Higgs potential. Our analysis shows that in this case the lightest Higgs boson mass has a certain upper bound, depending on the charged Higgs boson mass. In a specific case, the maximal value of $m_{H_1}$ is around 125 GeV for $m_{H^\pm} = 334 \text{ GeV}$ with the $CP$-violating phases being nearly maximal.

In this paper, it is assumed that the only sources of $CP$ violation come from the Higgs sector. Such $CP$-violating phases show up in the Higgs boson-mediated two-loop diagrams that contribute to the EDMs of electron, neutron and mercury atom. However, these diagrams are not important as long as $\tan \beta = 1$.

As pointed out in Ref. \[20\], a strong first order electroweak phase transition is possible in the sMSSM due to the presence of the trilinear term $\lambda A_\lambda S\Phi_d\Phi_u$. In this case, the light stop is not necessarily lighter than the top quark as required in the MSSM. A devoted study of the electroweak phase transition with/without $CP$ violation will be presented elsewhere \[48\].
A. The mass matrix of the neutral Higgs bosons at the tree level

Here we present explicitly the tree-level squared mass matrix elements for the neutral Higgs bosons. The \textit{CP}-even part is given by

\begin{equation}
\frac{1}{2} \left( h_O^T h_S^T \right) M_S^2 \left( h_O \right) , \quad M_S^2 = \left( \begin{array}{c}
M_S^{(O)} \\
M_S^{(OS)}
\end{array} \right) \left( \begin{array}{c}
M_S^{(O)} \\
M_S^{(OS)}
\end{array} \right)^T ,
\end{equation}

where

\begin{align}
(M_S^{(O)})_{11} &= \left[ \frac{g_2^2 + g_1^2}{4} + g_1^2 Q_{H_4}^2 \right] v_d^2 + R_\lambda \frac{v_u v_S}{v_d} , \\
(M_S^{(O)})_{22} &= \left[ \frac{g_2^2 + g_1^2}{4} + g_1^2 Q_{H_u}^2 \right] v_u^2 + R_\lambda \frac{v_d v_u}{v_u} , \\
(M_S^{(O)})_{33} &= \text{Re}(m_{S_1}^2 e^{i\phi_1}) \frac{v_{S_1}}{v_S} + \text{Re}(m_{S_2}^2 e^{i\phi_2}) \frac{v_{S_2}}{v_S} + R_\lambda \frac{v_d v_u}{v_S} + g_1^2 Q_S^2 v_S , \\
(M_S^{(O)})_{12} &= (M_S^{(O)})_{21} \left[ -\frac{g_2^2 + g_1^2}{4} + |\lambda|^2 + g_1^2 Q_{H_d} Q_{H_u} \right] v_d v_u - R_\lambda v_S , \\
(M_S^{(O)})_{13} &= (M_S^{(O)})_{31} = -R_\lambda v_u + (|\lambda|^2 + g_1^2 Q_{H_d} Q_{H_u}) v_d v_S , \\
(M_S^{(O)})_{23} &= (M_S^{(O)})_{32} = -R_\lambda v_d + (|\lambda|^2 + g_1^2 Q_{H_u} Q_{H_d}) v_u v_S , \\
(M_S^{(S)})_{11} &= \text{Re}(m_{S_1}^2 e^{i\phi_1}) \frac{v_{S_1}}{v_S} + \text{Re}(m_{S_2}^2 e^{i\phi_1}) \frac{v_{S_2}}{v_S} + R_\lambda \frac{v_d v_u}{v_{S_1}} + g_1^2 Q_S^2 v_{S_1} , \\
(M_S^{(S)})_{12} &= (M_S^{(S)})_{21} = \text{Re}(m_{S_2}^2 e^{i\phi_2}) - R_\lambda v_{S_2} + (|\lambda|^2 + g_1^2 Q_{S_1} Q_{S_2}) v_{S_1} v_{S_2} , \\
(M_S^{(S)})_{13} &= (M_S^{(S)})_{31} = -R_\lambda v_{S_2} + (|\lambda|^2 + g_1^2 Q_{S_1} Q_{S_2}) v_{S_1} v_{S_3} , \\
(M_S^{(S)})_{23} &= (M_S^{(S)})_{32} = -R_\lambda v_{S_1} + (|\lambda|^2 + g_1^2 Q_{S_2} Q_{S_3}) v_{S_2} v_{S_3} , \\
(M_S^{(OS)})_{11} &= g_1^2 Q_{H_d} Q_{S_1} v_d v_{S_1} , \\
(M_S^{(OS)})_{22} &= g_1^2 Q_{H_u} Q_{S_2} v_u v_{S_2} , \\
(M_S^{(OS)})_{33} &= g_1^2 Q_{S_1} Q_{S_2} v_{S_1} v_{S_2} , \\
(M_S^{(OS)})_{12} &= g_1^2 Q_{H_d} Q_{S_2} v_d v_{S_2} , \\
(M_S^{(OS)})_{13} &= g_1^2 Q_{H_u} Q_{S_1} v_d v_{S_1} , \\
(M_S^{(OS)})_{21} &= g_1^2 Q_{H_u} Q_{S_2} v_u v_{S_1} , \\
(M_S^{(OS)})_{23} &= g_1^2 Q_{H_d} Q_{S_3} v_u v_{S_3} , \\
(M_S^{(OS)})_{31} &= \text{Re}(m_{S_2}^2 e^{i\phi_2}) + g_1^2 Q S_{Q S_1} v_S v_{S_1} , \\
(M_S^{(OS)})_{32} &= \text{Re}(m_{S_2}^2 e^{i\phi_2}) + g_1^2 Q S_{Q S_2} v_S v_{S_2} .
\end{align}
The $CP$-odd part is given by

$$
\frac{1}{2} (a^T_O a^T_S) \mathcal{M}^P \left( \begin{array}{c} a_O \\ a_S \end{array} \right), \quad \mathcal{M}^P = \left( \begin{array}{cc} \mathcal{M}^{(O)}_P & \mathcal{M}^{(OS)}_P \\ (\mathcal{M}^{(OS)}_P)^T & \mathcal{M}^{(S)}_P \end{array} \right),
$$

where

$$
\mathcal{M}^{(O)}_P = \frac{R_\lambda}{v_d v_u} \left( \begin{array}{ccc} v_u^2 & v_d v_u & \frac{v_d^2}{v_u} \\ v_d^2 v_u & v_d^2 v_u & \frac{v_d^2}{v_u} \\ \frac{v_u v_d^2}{v_S} & \frac{v_u v_d^2}{v_S} & (\mathcal{M}^{(O)}_P)_{33} \end{array} \right), \quad \mathcal{M}^{(OS)}_P = \left( \begin{array}{ccc} 0 & 0 & 0 \\ 0 & 0 & 0 \\ \text{Re}(m^2_{S_{31} e^{i\phi_1}}) \text{Re}(m^2_{S_{32} e^{i\phi_2}}) & 0 \end{array} \right),
$$

$$
\mathcal{M}^{(S)}_P = \left( \begin{array}{ccc} (\mathcal{M}^{(S)}_P)_{11} & -\text{Re}(m^2_{S_{31} e^{i\phi_1}}) + R_\lambda v_{S_3} & R_\lambda v_{S_2} \\ -\text{Re}(m^2_{S_{31} e^{i\phi_1}}) & (\mathcal{M}^{(S)}_P)_{22} & R_\lambda v_{S_3} \\ R_\lambda v_{S_3} & R_\lambda v_{S_3} & R_\lambda v_{S_3} \end{array} \right),
$$

(\text{A.24})

with

$$
(\mathcal{M}^{(O)}_P)_{33} = \text{Re}(m^2_{S_{31} e^{i\phi_1}}) \frac{v_{S_3}}{v_S} + \text{Re}(m^2_{S_{32} e^{i\phi_2}}) \frac{v_{S_3}}{v_S} + R_\lambda \frac{v_d v_u}{v_S},
$$

$$
(\mathcal{M}^{(S)}_P)_{11} = \text{Re}(m^2_{S_{31} e^{i\phi_1}}) \frac{v_{S_3}}{v_S} + \text{Re}(m^2_{S_{31} e^{i\phi_1}}) \frac{v_{S_3}}{v_S} + R_\lambda \frac{v_{S_3}}{v_S},
$$

$$
(\mathcal{M}^{(S)}_P)_{22} = \text{Re}(m^2_{S_{32} e^{i\phi_2}}) \frac{v_{S_3}}{v_S} + \text{Re}(m^2_{S_{32} e^{i\phi_2}}) \frac{v_{S_3}}{v_S} + R_\lambda \frac{v_{S_3}}{v_S}.
$$

\text{(A.25)}

\text{(A.26)}

\text{(A.27)}

The mixing between $CP$-even and $CP$-odd parts is already given in the main text.
