Stoichiometry of altered hERG1 channel gating by small molecule activators

Wei Wu,1,2 Frank B. Sachse,2,3 Alison Gardner,1,2 and Michael C. Sanguinetti1,2

INTRODUCTION

Dysfunction of human ether-a-go-go-related gene (hERG) channels is implicated in several pathologies, including cardiac arrhythmia (Curran et al., 1995), cancer (Bianchi et al., 1998), epilepsy (Zamorano-León et al., 2012), and schizophrenia (Huffaker et al., 2009). In human heart, hERG1 channels conduct the rapid delayed rectifier K⁺ current (IKr) (Sanguinetti et al., 1995; Trudeau et al., 1995), a major determinant of cardiac action potential repolarization (Sanguinetti and Jurkiewicz, 1990). Reduced hERG1 function caused by mutation of KCNH2 (Curran et al., 1995) delays ventricular repolarization, prolongs duration of the QT interval, and increases the risk of life-threatening torsades de pointes arrhythmia and ventricular fibrillation (Keating and Sanguinetti, 2001). Torsades de pointes and ventricular fibrillation can also be caused by block of hERG1 channels by a wide variety of common medications (Fenichel et al., 2004). Thus, screening of new chemical entities for hERG1 channel block is now routinely performed during an early stage of the drug development process.

The large-scale screening of compounds for hERG1 channel activity fortuitously resulted in the discovery of several hERG1 activators (Kang et al., 2005; Zhou et al., 2005; Hansen et al., 2006; Perry et al., 2009; Gerlach et al., 2010). Refinement of target selectivity and safety of these agents may eventually provide a novel therapeutic approach for treatment of arrhythmias associated with inherited or acquired long QT syndrome. Two hERG1 agonists, PD-118057 (2-(4-[2-(3,4-dichloro-phenyl)-ethyl]-phenylamino)-benzoic acid; Zhou et al., 2005) and ICA-105574 (3-nitro-N-(4-phenoxyphenyl) benzamide; Kang et al., 2005), have been extensively characterized and shown to differentially affect hERG1 channel gating. Hereafter we abbreviate PD-118057 as PD and ICA-105574 as ICA. PD increases single channel open probability (P0) with a comparatively minor effect on inactivation and no effect on kinetics of activation or deactivation, single channel conductance, or gating currents (Zhou et al., 2005; Perry et al., 2009). ICA increases the magnitude of outward hERG1 currents by profound attenuation of inactivation (Gerlach et al., 2010; Garg et al., 2011). The putative binding sites for PD and ICA have been determined by a site-directed mutagenesis approach. Both compounds bind to a hydrophobic pocket located between adjacent hERG1 subunits. As voltage-gated K⁺ (Iv) channels are tetrameric complexes (MacKinnon, 1991), a homotetrameric channel would be expected to contain four identical activator binding sites.

It is unknown whether one or all four of the putative hERG1 agonist–binding sites must be occupied for full activity of compounds such as PD or ICA. Moreover, it is unknown whether ligand-bound subunits act independently...
to enhance channel currents or whether subunit cooperation is required. To answer these questions, we constructed concatenated hERG1 tetramers that contained a variable number (zero to four) of WT and mutant subunits with specified stoichiometry and geometry. Each mutant subunit contained a single amino acid substitution that disrupted a single PD- or ICA-binding site. Homotypic and heterotypic concatenated channels were heterologously expressed in Xenopus laevis oocytes, and the two-electrode voltage-clamp technique was used to characterize the effects of hERG1 agonists on channel properties. Our findings suggest that the full agonist activity of both compounds requires binding to multiple sites and involves cooperative subunit interactions.

MATERIALS AND METHODS

Construction of hERG1 concatamers
cDNAs were cloned into the pSP64 oocyte expression vector. Mutations in KCNH2 (hERG1, isoform 1a; NCBI Nucleotide accession no. NM_000238) were introduced using the QuikChange site-directed mutagenesis kit (Agilent Technologies). HindIII sites were used to link two KCNH2 monomers, and KpnI sites were used to link two KCNH2 tandem dimers. Details of how monomers and dimers were linked together to construct fully concatenated tetramers is described in Fig. S1. Each position within the KCNH2 tetramer was engineered to contain cDNA that encoded either a WT or a mutant subunit containing a single point mutation (L646E or F557L). All constructs were verified by DNA sequence analysis. Tetrameric KCNH2 plasmids were linearized with EcoR1 before in vitro transcription using the mMessage mMachine SP6 kit (Ambion).

Solutions and drugs
The extracellular solution used for voltage-clamp experiments contained (mM): 98 NaCl, 2 KCl, 1 CaCl₂, 1 MgCl₂, and 5 HEPES; pH was adjusted to 7.6 with NaOH. PD and ICA (Sigma-Aldrich) were individually dissolved in DMSO to make 20-mM stock solutions. Final drug concentrations of 1–30 µM (the limit of solubility) were obtained by dilution of the stock solution with extracellular solution immediately before use for each experiment.

Isolation and voltage clamp of Xenopus oocytes
Procedures used for the surgical removal of ovarian lobes from Xenopus and isolation of oocytes were approved by the University of Utah Institutional Animal Care and Use Committee and performed as described previously (Abbruzzese et al., 2010). Single oocytes were injected with 10 ng cRNA encoding single hERG1 subunits and studied 1–3 d later. hERG1 tandem dimers and concatenated tetramers expressed poorly, and therefore, oocytes were injected with 50 ng cRNA and studied 4–8 d later. Ionic currents were recorded using agarose-cushion microelectrodes (Schreibmayer et al., 1994) and standard two-electrode voltage-clamp techniques (Goldin, 1991; Stühmer, 1992). A GeneClamp 500 amplifier, Digidata 1322A data acquisition system, and pCLAMP 8.2 software (Molecular Devices) were used to produce command voltages and to record current and voltage signals.

Data analysis
Digitized data were analyzed offline with pCLAMP8 and ORIGIN 8.5 (OriginLab) software. To determine the conductance-voltage relationship, 4-s pulses were applied to test potentials (Vₜₐₜ) that ranged from −70 to 50 mV. Normalized conductance (G/Gₘₐₓ) defined as the amplitude of tail currents (Iₖₜₐₜ) measured at −70 mV normalized to their maximum value (Iₖₜₐₜ₇₀) was plotted as a function of Vₜₐₜ. The relationship was fitted with a Boltzmann function to determine the half-point (Vₜₐₜ₅₀ₐₜ₉₆ ) and the equivalent charge (z) for channel activation:

\[
\frac{I_{tail}}{I_{tail,max}} = \frac{G}{G_{max}} = \frac{1}{1 + e^{-(V_{tail} - V_{50, tail})/kT}},
\]

where F is the Faraday constant, R is the gas constant, and T is the absolute temperature. To estimate the voltage dependence of C-type inactivation, an initial 1-s pulse to 40 mV was followed by a 5-s pulse to a variable return potential (Vₑᵣᵱ) that ranged from 30 to −140 mV. For all channel types, Iᵣᵱ/Vₑᵣᵱ was plotted as a function of Vₑᵣᵱ, and the relationship was fitted with a Boltzmann function to estimate Vₛ; for inactivation (Vₛ,5ᵢₐₜ₉₆ ) and z.

The fold increase (FI) in hERG1 current (either Iₖₜₐₜ₉₆ or the magnitude of test currents, Iₖₜₐₜ₉₆) induced by drug was plotted as a function of [PD] or [ICA], and the resulting relationship was fitted with a modified logistic equation:

\[
FI = FI_{max} + \frac{1 - FI_{max}}{1 + ([drug]/EC₅₀)^{n_H}},
\]

where EC₅₀ is the concentration of compound that produced a half-maximal effect, and nₕ is the Hill coefficient. Data are presented as mean ± SEM (n = number of individual oocytes). Where appropriate, data were analyzed with a two-way ANOVA or paired Student’s t-test; P < 0.05 was considered significant. For some plots, the goodness of fit was evaluated by the coefficient of determination (adjusted R²).

Modeling of hERG1 channels
Markov models were developed to reconstruct measured currents of concatenated WT tetramers in the presence and absence of 30 µM PD or ICA. The models comprised five closed, one open, and one inactivated state (see Fig. 2 A). Coupling of states was described by transition rates. The transition rates α, β, and γ had constant values. Otherwise, forward rates α and backward rates β were defined as dependent on the transmembrane voltage Vₘᵢₜ:

\[
\alpha = \alpha_0 e^{V_m \beta / kT},
\]

\[
\beta = \beta_0 e^{-V_m \alpha / kT},
\]

with the rates α₀ and β₀ at 0 mV, the charges z₀ and z₀, and the temperature T (293 K). Current Iᵢₐₜ₉₆ conducted by concatenated tetramers was described as

\[
I_{iₐₜ₉₆} = G_{iₐₜ₉₆} \sqrt{\frac{K^+}{4mM}} \frac{z_0}{z_0} (V_m - E_K),
\]

with the conductance Gᵢₐₜ₉₆, the extracellular potassium concentration [K⁺], in mM, the reversal voltage E_K, and open state probability O (Iyer et al., 2004).

Parameters of the Markov models were determined using a previously developed stochastic multiscale fitting routine (Abbruzzese et al., 2010). In short, the fitting applied feature vectors were extracted from experimental data fₓ and compared with feature vectors of simulation data fₘ using a fit error function E, and E was iteratively minimized. Features were extracted from measured and simulated Iᵢₐₜ₉₆ at different voltages and

**RESULTS**

**Concatenated homotetrameric WT hERG1 channels have normal gating and pharmacology**

Ionic currents in *Xenopus* oocytes expressing single WT subunits or concatenated WT homotetramers (WT₄) measured by two-microelectrode voltage clamp had similar kinetics (Fig. 1 A). The voltage dependence of activation and C-type inactivation for these channels was nearly identical (Fig. 1 B), but as reported previously for concatenated Shaker K⁺ channels (Tytgat and Hess, 1992), the rate of deactivation of tail currents was slightly faster for WT₄ compared with WT hERG1 channels (Fig. 1 C). The effects of two hERG1 activators on the two channel types were also examined. At a concentration of 10 µM, PD

\[
E = \sqrt{\sum_{j=1}^{n} \left( \frac{f_{o,j} - f_{c,j}}{f_{o,j}} \right)^2 + \left( 1 - \text{Max} \sum C_j \right)^2} + \left( \text{Max} - \text{Max} O \right)^2 + \left( 1 - \text{Max} \left( C_4 + O + I \right) \right)^2
\]

with the number of features \(n\), the Euclidean norm \(\| \cdot \|_E\), the maximal closed state probability at the end of the prepulse \(\text{Max} \sum C_j\), the maximal open state probability \(O\) during the test pulses, a predefined maximal open state probability \(O_{\text{max}}\), the maximal probability of the fourth closed state \(C_4\) during the test pulses, and the maximal probability of the inactivated state \(I\) during the test pulses. \(O_{\text{max}}\) was set to 0.1 in parameter optimization of the control model. \(O_{\text{max}}\) for PD and ICA models was scaled by the ratio of maximal \(I_{\text{test-end}}\) after activator application and maximal \(I_{\text{test-end}}\) under control conditions. \(O_{\text{max}}\) was calculated for each parameter set during stochastic optimization aimed at minimizing the difference between \(\text{Max} \sum O\) and \(O_{\text{max}}\). Modeling and parameter fitting software was implemented in Matlab R2011b (The Mathworks Inc.) and the Matlab Parallel Computing Toolbox. Simulations were performed with variable order method for solution of ordinary differential equations based on numerical differentiation formulas (Matlab function: ode15s) using an initial time step \(\Delta t\) of 1 ms. The initial value for the state \(C_0\) was 1. Initial values for all other states were 0.

![Figure 1](https://example.com/figure1.png)

**Figure 1.** Concatenated tetrameric hERG1 (WT₄) channels have similar biophysical and pharmacological properties as channels formed by coassembly of single WT hERG1 subunits. (A) Representative WT and WT₄ hERG1 channel currents recorded at the indicated voltages. (B) The voltage dependence of WT channel gating (upright green triangles, activation; sideways green triangles, C-type inactivation) is similar to WT₄ channels (upside-down black triangles, activation [\(n = 6\)]; sideways black triangles, C-type inactivation [\(n = 8\)]). Data were fitted to Boltzmann function (smooth curves) to determine \(V_{0.5}^{\text{act}}\) and \(z\) values (presented in Table 1). (C) Time constants (\(\tau_{\text{deact}}\)) for fast and slow components of current deactivation for WT (green triangles, \(n = 10\)) and WT₄ (black triangles, \(n = 11\)) channels at the indicated return potential (\(V_{\text{ref}}\)). (D) Effect of 10 µM PD on WT and WT₄ hERG1 channel currents elicited by 4-s step to 0 mV. \(I_{\text{test-end}}\) was measured at \(-70\) mV. (E and F) \(I_{\text{test<V}_{\text{ref}}}\) relationships in the absence (black triangles) and presence of 10 µM PD (red triangles) for oocytes injected with cRNA encoding single WT subunits (\(E, n = 10\)) or WT₄ channels (\(F, n = 5\)). Data are expressed as mean ± SEM (\(n = \) number of oocytes).

Wu et al. 501
increased \( I_{test} \) measured at the end of 4-s pulses about twofold with no change in kinetics for both WT and WT\(_4\) hERG1 channels (Fig. 1, D–F). ICA at 10 \( \mu M \) induced a much larger increase in \( I_{test} \) magnitude and slowed current deactivation in both WT and WT\(_4\) hERG1 channels (Fig. 1 G). Consistent with the known inhibitory effects of ICA on inactivation, enhancement of current was voltage dependent (e.g., 4- and 20-fold increase at \(-30 \) mV and \(20 \) mV, respectively), resulting in reduced rectification of the isochronal (4 s) \( I_{test}/V_{t} \) relationships (Fig. 1, H and I). Thus, the biophysical and pharmacological properties of hERG1 channels were similar whether formed by cellular coassembly of single subunits or preformed by concatenation of four identical protomers.

Markov models of hERG1 channel gating

Markov models were developed to quantitatively describe the changes in gating of WT\(_4\) channels induced by 30 \( \mu M \) PD or ICA. The models comprised five closed states, one open, and one inactivated state (Fig. 2 A). Rate coefficients of the models were determined by a previously developed stochastic optimization approach (Abbruzzese et al., 2010) using features extracted from averaged current traces. The WT\(_4\) model reconstructs major features of measured currents (Fig. 2, B and C), in particular, voltage-dependent activation, rapid recovery from inactivation, and slow deactivation. Fig. 2 (D and E) presents averaged measured current traces of concatenated WT\(_4\) tetramers after application of 30 \( \mu M \) PD together with simulated currents. To simulate the effects of PD, several rate coefficients were altered, including reduction of \( \alpha_{OI} \) by 76\% and \( \beta_{OI} \) by 46\% (Table S1). Fig. 2 (F and G) presents averaged measured current traces of concatenated WT\(_4\) tetramers after application of 30 \( \mu M \) ICA together with simulated currents. To simulate the effects of ICA, the main changes were a reduction of \( \alpha_{OI} \) to 0.1\% and \( \beta_{OI} \) to 6.7\% (Table S2). Tables S3 and S4 list the features for fitting and fit errors for the PD and ICA models. Alterations in multiple gating parameters predicted by these models precluded simple analysis of drug effects on the heterotypic channels.

Cooperative subunit interactions mediate the agonist activity of PD

Using a combined approach of functional analysis of mutant channels and molecular modeling, the putative binding site for PD was previously shown to be localized to a hydrophobic pocket between the S5 and S6 segments of adjacent hERG1 subunits (Perry et al., 2009). A point mutation in S6 (L646E) eliminated activity of PD, and molecular modeling predicted this was caused by steric interference with ligand binding (Perry et al., 2009). A homotetrameric hERG1 channel has four identical intersubunit PD binding sites, but it is unknown whether drug binding to one or multiple sites is required to enhance channel currents. Six concatenated tetramers containing a variable number (zero to four) of L646E subunits were constructed (Fig. S1). These channels are designated here as LE\(_n\)/WT\(_{4-n}\), where LE represents L646E mutant subunits, WT represents WT hERG1 subunits, and the subscript \( n \) indicates the number of L646E subunits in a concatenated tetramer. Included in the constructs were two tandem dimers in which WT subunits were located in an adjacent (LE\(_2\)/WT\(_2\)) or diagonal (LE\(_1\)/WT\(_1\)/LE\(_1\)/WT\(_1\)) orientation and two tetramers containing a single L646E subunit in either the first (LE\(_1\)/WT\(_3\)) or last (WT\(_3\)/LE\(_1\)) position.
compound was an increase in the magnitude of $I_{\text{tail}}$ measured upon repolarization to $-70$ mV. The voltage dependence of homotypic or heterotypic channel activation, determined by fitting the $I_{\text{tail}}$-$V_r$ relationship to a Boltzmann function, was not altered by 10 µM PD (Fig. 4 B and Table 1), but $I_{\text{tail}}$-max was increased as the number of WT subunits was increased from one to four (Fig. 4 B). C-type inactivation is modestly inhibited by PD (Perry et al., 2009). However, based on an analysis of $I_{\text{tail}}$, most of the agonist effects of PD can be attributed

Figure 3. Biophysical properties of concatenated LE$_{n}$/WT$_{4-n}$ tetrameric hERG1 channels. (A) $I_{\text{test}}$-$V_r$ relationships. (B) Voltage dependence of activation. (C) Fully activated $I_{\text{tail}}$-$V_r$ relationships. (D) Voltage dependence of inactivation. Legend refers to all panels. Data are expressed as mean ± SEM ($n = 5–12$; values for $V_{0.5}$ and $z$ for activation and inactivation are presented in Table 1; $n = number of oocytes$).

**Table 1**

Summary of effects of PD on the voltage dependence of activation and inactivation for hERG1 monomers (WT) and tetramers containing zero to four L646E (LE) subunits

| Channel type | Control $V_{0.5}$ | Control $z$ | 10 µM PD $V_{0.5}$ | 10 µM PD $z$ |
|--------------|-------------------|-------------|---------------------|-------------|
| $I_{\text{act}}$ |                   |             |                     |             |
| WT hERG1     | $-29.8 \pm 0.8$   | $3.41 \pm 0.09$ | $-29.2 \pm 14$     | $3.07 \pm 0.34$ |
| WT$_4$       | $-29.1 \pm 0.9$   | $3.45 \pm 0.33$ | $-26.7 \pm 1.0$    | $3.07 \pm 0.30$ |
| LE$_1$/WT$_3$| $-32.1 \pm 1.3$   | $4.13 \pm 0.14$ | $-30.1 \pm 1.6$    | $4.20 \pm 0.07$ |
| WT$_3$/LE$_1$| $-29.1 \pm 1.5$   | $3.36 \pm 0.21$ | $-27.1 \pm 1.29$   | $3.44 \pm 0.16$ |
| LE$_1$/WT$_3$/LE$_2$/WT$_1$| $-36.7 \pm 0.5$ | $3.23 \pm 0.08$ | $-32.7 \pm 0.8$   | $3.45 \pm 0.19$ |
| LE$_2$/WT$_2$| $-35.4 \pm 0.8$   | $3.88 \pm 0.12$ | $-31.3 \pm 1.0$    | $3.94 \pm 0.12$ |
| LE$_1$/WT$_3$/LE$_2$| $-33.5 \pm 1.6$ | $3.41 \pm 0.18$ | $-30.3 \pm 1.4$   | $3.55 \pm 0.15$ |
| LE$_4$       | $-36.5 \pm 1.0$   | $3.55 \pm 0.20$ | $-32.6 \pm 1.2$    | $3.55 \pm 0.25$ |
| $I_{\text{inact}}$ |                   |             |                     |             |
| WT hERG1     | $-55.8 \pm 3.7$   | $1.19 \pm 0.02$ | $-34.7 \pm 4.2$    | $1.19 \pm 0.09$ |
| WT$_4$       | $-55.7 \pm 0.7$   | $1.10 \pm 0.02$ | $-39.4 \pm 4.6$    | $1.26 \pm 0.17$ |
| LE$_1$/WT$_3$| $-48.5 \pm 2.7$   | $1.02 \pm 0.05$ | $-44.6 \pm 2.7$    | $1.24 \pm 0.10$ |
| WT$_3$/LE$_1$| $-37.4 \pm 3.0$   | $1.23 \pm 0.02$ | $-33.5 \pm 3.7$    | $1.44 \pm 0.19$ |
| LE$_1$/WT$_3$/LE$_2$/WT$_1$| $-42.6 \pm 3.6$ | $1.08 \pm 0.05$ | $-43.3 \pm 3.4$   | $1.22 \pm 0.07$ |
| LE$_2$/WT$_2$| $-45.7 \pm 1.9$   | $1.07 \pm 0.03$ | $-45.5 \pm 2.8$    | $1.19 \pm 0.08$ |
| LE$_1$/WT$_3$/LE$_2$| $-44.3 \pm 5.5$ | $1.27 \pm 0.08$ | $-47.7 \pm 4.0$   | $1.31 \pm 0.08$ |
| LE$_4$       | $-41.4 \pm 1.6$   | $1.49 \pm 0.04$ | $-43.6 \pm 2.2$    | $1.52 \pm 0.05$ |

Data are expressed as mean ± SEM ($n = number of oocytes$).
to its effect on $P_o$. Tail currents elicited at a variable return potential ($V_{ret}$) after a 1-s pulse to 40 mV (Fig. 4 C) were used to construct a fully activated $I_{tail}$-$V_{ret}$ relationship (Fig. 4 D). The increase in $I_{tail}$ at −140 mV (68%), where recovery from inactivation is complete, was nearly equivalent to the increase in $I_{tail}$ at −70 mV (81%), where recovery from inactivation is ~70% complete. Therefore, $I_{tail,max}$ at −70 mV can be used to approximate changes in $P_o$.

The fold increase in $I_{tail,max}$ by PD was concentration dependent for WT4 and the heterotypic tetramers (Fig. 4 E); however, there was no significant correlation between the number of WT subunits present in a concatemer and the EC$_{50}$ or $n_H$ for PD (Fig. 5). This finding suggests that ligand binding is not cooperative. Extrapolation of the concentration-response relationship for WT4 channels (Fig. 4 E) indicates that PD is predicted to increase $I_{tail,max}$ by a maximum of 1.9-fold, perhaps limited by a saturating effect on the channel open probability $P_o$. The maximum $P_o$ of WT hERG1 has not been determined because at positive potentials where channels are maximally activated they are also highly inactivated. The $P_o$ of inactivation-deficient S631A mutant channels is ~0.5 at potentials between 40 and 80 mV (Zou et al., 1998). Assuming a maximum $P_o$ of 0.5 for WT4 channels in the absence of drug, we estimated $P_o$ for each tetrameric channel from the maximum fold increase in $I_{tail,max}$ determined from extrapolation of the [PD]-response relationships as shown in Fig. 4 E. Estimates of the equilibrium constant Keq ($P_o/(1 - P_o)$) were then used to calculate the free energy change associated with channel activation: $\Delta G = -RT\ln Keq$. If subunits acted completely independently of one another, where a conformational change in any single PD-bound WT subunit was sufficient to achieve maximal agonist activity of the compound, then $\Delta G$ for all of the heterotypic channels would be predicted to be the same as WT4.

**Figure 4.** PD-induced enhancement of hERG1 current indicates cooperative subunit interactions. (A) Representative current traces recorded at 0 mV for concatenated tetramers containing zero to three WT subunits together with one to four L646E subunits, before and after 10 µM PD. (B) Effect of 10 µM PD on voltage dependence of channel activation. $I_{tail}$ measured at −70 mV after pulses to the indicated $V_t$ and normalized to $I_{tail,max}$ under control conditions for each channel type ($n = 7–15$). The symbol legend between B and E refers to data plotted in B and D–F. Control $I_{tail}$-$V_t$ relationship (black pentagons) overlaps data for LE4 channels and represents the mean of all channel types. The $V_{0.5}$ and z values obtained from fitting $I_{tail}$-$V_t$ relationships to a Boltzmann function (smooth curves) before and after 10 µM PD are presented in Table 1. (C) Pulse protocol (top) used to measure fully activated $I_{tail}$-$V_{ret}$ relationship and representative currents for WT4 channels under control conditions and after 10 µM PD as indicated. (D) Effect of 10 µM PD on $I_{tail}$-$V_{ret}$ relationships ($n = 4–9$) normalized to $I_{tail}$ at −120 mV under control conditions for LE$_n$/WT$_{4-n}$ tetramers ($n = 0–4$). (E) [PD]-response relationships for fold increase in $I_{tail,max}$ at −70 mV for different tetramers according to symbol legend shown between B and E. Data were fitted with a logistic equation to determine EC$_{50}$ values and Hill coefficient, $n_H$ (see Fig. 5). (F) Plot of $\Delta G$ versus number of WT subunits contained in a concatenated tetramer. $\Delta G$ was equal to $-RT\ln Keq$, where Keq was defined as $P_o/(1 - P_o)$ at maximal effect of PD and assuming maximum $P_o$ in the absence of drug to be 0.5. Linear regression analysis was used to fit calculated data (colored symbols; solid line: $y = -0.39x + 0.058; R^2 = 0.96$) and the relationships predicted for independent subunit transitions (▼) and cooperative subunit interactions, models 1 (▲) and 2 (●). Data are expressed as mean ± SEM ($n = number of oocytes$).
channels (Fig. 4 F, ▼). This model of independence is exemplified by N-type inactivation of Kv1 channels, where any one and only one N-terminal ball peptide is sufficient to induce inactivation (MacKinnon et al., 1993), and by the independent outward movement of S4 segments in response to membrane depolarization. As described in a previous study of the conformational changes that lead to activation gate opening in Shaker K+ channels (Zandany et al., 2008), we considered two mechanistic models of subunit cooperativity. The first model is analogous to the Monod-Wyman-Changeux (Monod et al., 1965) allosteric model of ligand binding to multisubunit proteins. This model is exemplified by the final concerted step of Kv channel activation where a simultaneous conformational change in all four subunits leads to channel opening (Sigworth, 1994; Zagotta a simultaneous conformational change in all four subunits leads to channel opening (Sigworth, 1994; Zagotta et al., 1994), as directly demonstrated using concatenated heterotetrameric Shaker K+ channels composed of WT and mutant subunits harboring a mutation that disrupts function of the S6 glycine hinge (Zandany et al., 2008). If fully concerted, all-or-none cooperation between subunits underlies the agonist activity of PD, then the $\Delta G$ for all the heteromeric channels would be predicted to be the same as LE4 channels (Fig. 4 F, ▲). The second model of cooperativity assumes an equal energetic contribution from each subunit to the tetrameric channel function. In this model, the predicted net free energy of a tetramer ($\Delta G$) would be the sum of the individual values contributed by each of the WT and mutant LE subunits as follows:

$$\Delta G_{\text{het}} = \frac{n \Delta G_{\text{WT4}}}{4} + \frac{(4-n) \Delta G_{\text{LE4}}}{4},$$

where $n$ equals the number of WT subunits in a tetramer and $\Delta G_{\text{WT4}}$ and $\Delta G_{\text{LE4}}$ are the free energy values calculated for WT4 and LE4 homotypic tetramers, respectively. This model of cooperativity (Fig. 4 F, ▼) describes the subunit interactions that underlie the steady-state voltage dependence of activation (Hurst et al., 1992; Smith-Maxwell et al., 1998) and slow C-type inactivation (Ogielska et al., 1995; Panyi et al., 1995) in Kv channels.

The experimentally determined values of $\Delta G (-RT \ln K_{eq})$ were plotted as a function of the number of WT subunits in a concatenated tetramer in Fig. 4 F. The data closely match the $\Delta G$ values predicted for cooperativity model 2. Thus, PD-bound subunits contribute equally to the enhancement of currents conducted by hERG1 tetrpaners.

It is notable that LE1/WT1/LE1/WT1 channels had a greater response to PD than did the LE2/WT2 channels. The positioning of a mutant subunit within concatenators can affect the biophysical properties of K+ channels (McCormack et al., 1992), and perhaps the pharmacological responses to drugs. To examine this possibility in more detail, we determined whether the biophysical properties or response to PD of WT1/LE1 channels differed from LE1/WT1 channels. These channels did not appreciably differ with respect to kinetics (Fig. 6 A), voltage dependence

**Figure 5.** The concentration response relationship for PD-induced increase in $I_{\text{act}}$ is not dependent on the number of WT subunits in a concatenated tetramer. (A) Plot of $E_{50}$ for a function of the number of WT subunits in a tetramer. Line represents linear fit to data: $y = 0.64x + 1.22$ (adjusted $R^2 = 0.999$). (B) Plot of $n_{H}$ as a function of number of WT subunits in a tetramer. Line represents linear fit to data: $y = -0.015x + 1.24$ (adjusted $R^2 = -0.473$). In both panels, the open circle represents LE1/WT3/LE1/WT3 channels; the open square represents WT2/LE1 channels.

**Figure 6.** Positioning of a single LE mutant subunit in a concatenated hERG1 tetramer does not affect biophysical properties or response to PD. (A) Representative current traces for LE1/WT1 and WT1/LE1 hERG1 channels. Pulses were applied to $V_t$ of −70 to 30 mV in 20-mV increments. $V_{p0}$ was −80 mV and $V_{r}$ was −70 mV. (B) Normalized $I_{\text{act}}$-Vt relationships before and after 10 µM PD. Symbol legend is the same as for C. For LE1/WT3 hERG1 channels: $V_{p0}$, −32.1 ± 1.3 mV; $z$, 4.13 ± 0.14 mV (control); $V_{p0}$, −30.1 ± 1.6 mV; $z$, 4.20 ± 0.07 mV (PD; $n$ = 11). For WT1/LE1 hERG1 channels: $V_{p0}$, −29.1 ± 1.5 mV; $z$, 3.36 ± 0.21 mV (control); $V_{p0}$, −27.1 ± 1.3 mV; $z$, 3.44 ± 0.16 mV (PD; $n$ = 4). (C) Normalized fully activated $I_{\text{act}}$-Vt relationships determined before and after 10 µM PD. (D) [PD]-response relationships for LE1/WT3 hERG1 channels ($E_{50}$ = 4.6 µM, $n_{H}$ = 1.1; $n$ = 6–9) and WT1/LE1 hERG1 channels ($E_{50}$ = 4.8 µM, $n_{H}$ = 1.4; $n$ = 4). Data are expressed as mean ± SEM ($n$ = number of oocytes).
of activation (Fig. 6 B), shape of the fully activated I-V relationship (Fig. 6 C), or response to PD (Fig. 6 D). Thus, unlike channels with two WT and two mutant subunits, placing a single L646E subunit in the first or fourth position of an hERG1 tetramer did not affect the biophysical properties or response to PD. A full test of the importance of mutant subunit positioning and confirmation of sequential cooperativity (Zandany et al., 2008) would require examination of all possible heteromeric tetrasmers.

Cooperative subunit interactions mediate attenuation of C-type inactivation by ICA

The same concatenation strategy used to characterize PD was used to study ICA, a compound which enhances hERG1 current by strongly inhibiting channel inactivation (Gerlach et al., 2010). WT subunits were linked to a variable number of subunits containing the point mutation F557L, which prevents ICA binding (Garg et al., 2011). Representative current traces recorded during 4-s test pulses and their corresponding $I_{\text{test}}-V_t$ relationships for the different concatemers are shown in Fig. 7 (A and B). Compared with WT4 channels, the presence of F557L mutant subunits in a concatenated tetramer induced a faster rate of current deactivation (Fig. 7 A) and produced a 5- to 14-mV shift in the voltage dependence of activation (Fig. 7 C and Table 2). In addition, for tetrasmers with F557L subunits, inward rectification of the fully activated $I_{\text{tail}}-V_t$ relationship was accentuated (Fig. 7 D), and the voltage dependence of inactivation was shifted to more negative potentials (Fig. 7 E and Table 2), similar to channels formed by natural coassembly of F557L monomers (Perry et al., 2007). Thus, unlike the L646E mutation used to disrupt binding of PD, the F557L mutation altered the biophysical properties of hERG1 tetrasmers.

We next determined the effects of ICA on FLn/WT4–n tetrameric channels. The increase in current at a $V_t$ of 20 mV was ~13-fold greater for WT4 channels compared with FL4/WT/FL2 channels; however, the EC$_{50}$ and $n_H$ values were similar (Fig. 8 A). Representative current traces recorded during 4-s pulses to 0 mV in the absence and presence of 10 µM ICA are illustrated for several tetrasmers in Fig. 9 A. The $I_{\text{test}}-V_t$ relationships illustrates that the effect of 30 µM ICA was enhanced at positive test potentials and by increasing the number of WT subunits (i.e., the number of functional ICA binding sites) in a tetramer (Fig. 9 B). Increasing the number of available binding sites per channel from zero (FL4) to one (FL4/WT/FL2) to two (FL4/WT/FL4/WT1) caused a simple additive increase in the response to 30 µM ICA, whereas addition of a third (FL4/WT3) and a fourth (WT4) binding site resulted in a greater than additive effect for test potentials ranging from 0 to 40 mV (Fig. 8 B). hERG1 channels are fully activated at 20 mV. Therefore, $I_{\text{test}}$ measured at 20 mV was used to compare the efficacy (maximal effect) of ICA for the various tetrasmers. The increase in $I_{\text{est}}$ at 20 mV varied as a logarithmic function of the number of WT subunits contained in a tetramer (Fig. 9 C). Opposite to PD, channels with adjacent positioning of WT subunits (FL2/WT2) were increased by ICA more than channels with diagonally oriented WT subunits (FL1/WT1/FL1/WT1; Fig. 9, B and C).

The effect of ICA on the voltage dependence of inactivation as a function of the number of WT subunits in a tetramer was determined. The effect of 30 µM ICA on fully activated $I_{\text{tail}}-V_{\text{ret}}$ relationships for FL4/WT3 and FL4/WT1/FL2 channels are compared in Fig. 9 D. ICA had only minor effects on the $I_{\text{tail}}-V_{\text{ret}}$ relationship for FL4/WT1/FL2 channels but markedly reduced inward
rectification of FL₁/WT₃ channel currents. The effects of 30 µM ICA on the voltage dependence of inactivation of these two channel types are compared in Fig. 9 E. ICA caused a large positive shift in \( V_{0.5 \text{ inact}} \) (70 ± 3 mV; \( n = 4 \)) of this relationship for FL₁/WT₃ channels but only a small shift in \( V_{0.5 \text{ inact}} \) (6.6 ± 1.6 mV; \( n = 4 \)) for FL₂/WT₁/FL₂ channels. The effect of ICA on \( V_{0.5 \text{ inact}} \) and \( z \) for all the concatenated tetramers are presented in Table 2. We suspected that the increase in \( I_{\text{tail}} \) at potentials negative to the reversal potential observed for FL₁/WT₃ channels (Fig. 9 D) and WT₃ channels (not depicted) resulted from an increased electrochemical gradient caused by extracellular K⁺ accumulation associated with large outward currents that occur during the prepulse to 80 mV. To test for this possibility, we determined the effect of 30 µM ICA on the \( I_{\text{tail}}V_{\text{act}} \) relationship for WT₄ channels using a bath solution containing 20 mM KCl to greatly reduce the effect of extracellular K⁺ accumulation caused by pulsing to 80 mV. Under these conditions, ICA did not cause an increase in \( I_{\text{tail}} \) at potentials more negative than −100 mV (Fig. 9 F), indicating that the increase in currents results from reduced inactivation and not an increase in maximum \( P_{\text{o}} \) of channels.

The \( V_{0.5 \text{ inact}} \) and \( z \) values determined from inactivation curves were used to estimate the free energy change associated with channel inactivation (\( \Delta G \)):

\[
\Delta G = z \cdot F \cdot V_{0.5 \text{ inact}}.
\]

ICA-induced perturbations in \( \Delta G \) (\( \Delta \Delta G \)) were calculated for each concatenated tetramer as

\[
\Delta \Delta G = |\Delta G_{\text{ICA}} - \Delta G_{\text{con}}|.
\]

where \( \Delta G_{\text{con}} \) equals \( zFV_{0.5 \text{ inact}} \) before drug, and \( \Delta G_{\text{ICA}} \) equals \( zFV_{0.5 \text{ inact}} \) determined in the presence of 30 µM ICA.

If each ICA-bound subunit contributes equally to disruption of inactivation (model 2), then the predicted change in free energy (\( \Delta \Delta G \)) of a heteromeric tetramer would be the sum of the individual \( \Delta \Delta G \) values contributed by each of the WT and F557L subunits in a tetramer as follows:

\[
\Delta \Delta G = \frac{n\Delta \Delta G_{WT4}}{4} + \frac{(4-n)\Delta \Delta G_{FL4}}{4}.
\]

For this model, \( \Delta \Delta G \) would be predicted to be a linear function of the number of WT subunits in a concatenated tetramer. Fully concerted cooperativity (model 1) predicts that a single ICA-bound WT subunit would disrupt inactivation to the same extent as channels containing two, three, or four WT subunits per tetramer. In Fig. 9 G, the experimentally determined \( \Delta \Delta G \) values are plotted as a function of the number of WT subunits contained in a tetramer. The change in \( \Delta \Delta G \) between FL₁/WT₃ and FL₁/WT₁/FL₂ and FL₂/WT₂ was small compared with the change between tetramers with three or four WT subunits. Overall, the relationship between calculated \( \Delta \Delta G \) and the number of WT subunits (i.e., available ICA-binding sites) was intermediate between the linear function predicted for model 2 cooperative subunit interactions and the step function predicted for a fully concerted process requiring the simultaneous cooperation of all four subunits (model 1).

**Table 2**

| Channel type         | Control | 30 µM ICA | \( n \) |
|----------------------|---------|-----------|--------|
|                      | \( V_{0.5} \) | \( z \) | \( V_{0.5} \) | \( z \) |
| \( V_{0.5 \text{ inact}} \) | mV | mV |
| WT₄                  | −30.2 ± 1.0 | 3.76 ± 0.22 | ND* | ND* | 12 |
| FL₁/WT₃              | −25.0 ± 0.6 | 3.76 ± 0.17 | −34.5 ± 1.5 | 4.06 ± 0.39 | 5 |
| WT₃/FL₁              | −26.9 ± 0.9 | 3.32 ± 0.05 | −36.7 ± 1.1 | 3.57 ± 0.39 | 4 |
| FL₁/WT₁/FL₁/WT₁      | −22.7 ± 1.1 | 2.60 ± 0.05 | −29.6 ± 1.6 | 3.00 ± 0.25 | 4 |
| FL₂/WT₂              | −26.0 ± 1.7 | 3.04 ± 0.15 | −37.1 ± 0.4 | 3.88 ± 0.48 | 4 |
| FL₁/WT₁/FL₂          | −22.0 ± 2.7 | 3.36 ± 0.18 | −19.5 ± 2.9 | 2.80 ± 0.22 | 4 |
| FL₄                  | −16.4 ± 3.3 | 3.11 ± 0.15 | −18.7 ± 1.0 | 3.60 ± 0.15 | 3 |
| \( V_{0.5 \text{ inact}} \) | mV | mV |
| WT₄                  | −54.4 ± 2.6 | 1.06 ± 0.03 | 57.8 ± 4.1 | 1.17 ± 0.05 | 5 |
| FL₁/WT₃              | −45.8 ± 3.0 | 1.00 ± 0.04 | 28.5 ± 6.0 | 0.95 ± 0.13 | 4 |
| WT₃/FL₁              | −57.8 ± 4.4 | 0.90 ± 0.03 | 49.9 ± 4.0 | 1.21 ± 0.03 | 4 |
| FL₁/WT₁/FL₁/WT₁      | −51.1 ± 14.3 | 0.80 ± 0.05 | −33.7 ± 16.0 | 0.56 ± 0.03 | 4 |

| FL₄                  | −103.7 ± 2.4 | 0.65 ± 0.05 | −98.8 ± 7.8 | 0.69 ± 0.04 | 3 |

Data are expressed as mean ± SEM (\( n \) = number of oocytes).

*Not able to measure accurately because tail currents were affected by extracellular K⁺ accumulation associated with very large outward currents.
DISCUSSION

Construction of plasmids for expression of concatenated proteins enables the characterization of heterooligomeric protein complexes with precisely defined subunit stoichiometry and geometry. Tandem hERG1 dimers were previously used to characterize binding of hERG1 inhibitors (Imai et al., 2009), but our study is the first to construct and characterize concatenated tetramers for this channel. We took advantage of our previous finding that L646E and F557L mutations nearly abolish the ability of PD and ICA, respectively, to enhance hERG1 currents. Molecular modeling suggests that these mutations interfere with ligand binding, although competitive radiolabeled ligand displacement studies are needed to confirm this prediction and rule out the possibility that the mutations instead disrupt the ability of bound ligand to allosterically alter channel gating.

Concatenated subunits have previously been used to study several voltage-gated K+ and ligand-gated channels (Isacoff et al., 1990; Yang et al., 1997; Morrill and MacKinnon, 1999; Minier and Sigel, 2004; Sack et al., 2008). Although unusual stoichiometry was observed in some cases (McCormack et al., 1992; Hurst et al., 1995; Sack et al., 2008), concatenated channels can be properly assembled by linking nearly identical subunits (e.g., WT subunits plus subunits containing a single point mutation; Hurst et al., 1992; Sack et al., 2008). However, formation of multimerized concatamers, where two or more tetramers combine to form a functional channel sometimes by exclusion of a mutant subunit, has been described for Kv1.1 (Hurst et al., 1995). In this study, the authors introduced a Pro residue into the S4 segment and a point mutation to alter sensitivity to TEA in one or more subunits of a concatenated tetramer. Analysis of the voltage dependence of activation and block by TEA revealed that Pro-containing subunits were apparently excluded from functional channels, implying that two or more tetramers combined to form a functional channel. Pro substitutions greatly suppressed functional channel expression as currents were only measurable if 100–1,000× more cRNA was injected than was required for expression of WT4 Kv1.1 channels. In contrast, several features of the tetramer channels we studied suggest that multimerized concatamers were not formed. First, we found that the expression level of concatenated hERG1 tetramers were the same regardless of the number of mutant subunits per tetramer. Second, there was a graded response to drug for tetramers containing variable numbers of F557L or L646E subunits, despite similar biophysical properties measured in the absence of the drug. Third, F557L mutations cause a negative shift in V0.5inact when F557L monomers are expressed in oocytes, and in tetramers containing two or more F557L subunits, there was a progressive negative shift in the V0.5inact. Fourth, for both mutations studied (L646E and F557L), there were no significant differences in the biophysical properties of channels where the single mutant subunit was placed in the first or fourth position of the heterotypic tetramer. Moreover, the response to PD or ICA was not altered when the mutant subunit was placed in either the first or last position. We also examined how positioning two WT plus two mutant subunits with like subunits in a diagonal versus an adjacent orientation affected channel properties for all three mutations. The biophysical properties of these channels were similar, whereas the response to drug varied. Although this finding indicates differential effects of drug binding on channel gating, it does not imply that multimerized concatamers were formed.

Positive cooperativity of oligomeric protein function can result when ligand occupancy of one site enhances the ligand affinity of other unbound sites (e.g., O2 binding to tetrameric hemoglobin [Hill, 1910; Perutz, 1970]) or by cooperative interactions between protomers that can result from ligand binding to multiple sites with the same or similar affinity. The EC50 and nH for PD effects were independent of the number of WT subunits present in a concatenated tetramer, indicating occupancy of one binding site does not lead to enhancement of PD affinity of other sites. Hill coefficients (nH) >1 derived from fitting the concentration-response relationships for ICA on WT channels indicate positive cooperativity, an effect which could arise from differential affinity of the four available binding sites. For a receptor with four ligand-binding sites, the binding affinity for each successive ligand-bound state would have to increase by an order of magnitude for nH to reach a value of 4 (Weiss, 1997). Although the efficacy (maximal effect) of ICA varied for concatenated tetramers containing a variable number of available ligand-binding sites, there was little difference between the EC50 or nH values for WT4 and FL1/WT1/FL2 channels. Thus, we conclude that the agonist effects of PD and ICA on hERG1

Figure 8. Concentration- and voltage-dependent effects of ICA on Iinact. (A) Concentration-dependent increase in Iinact measured at 20 mV by ICA for WT1 and FL1/WT1/FL2 hERG1 concatenated channels. Data were fitted with a logistic equation (smooth curves). For WT1 channels: EC50 = 9.1 µM, nH = 1.7 (n = 6–9); for FL1/WT1/FL2 channels: EC50 = 11.8 µM, nH = 2.0 (n = 6–10). (B) Fold increase in Iinact by 30 µM ICA as a function of Vt (n = 3–8). Data are expressed as mean ± SEM (n = number of oocytes).
Wu et al. used to interrogate channel function. We examined the effects of two hERG1 agonists with different mechanisms of action but with overlapping binding sites. Both PD and ICA bind to a hydrophobic pocket located between two adjacent hERG1 subunits, and thus, a homotetrameric channel has four identical binding sites. The ability of PD to increase current magnitude, quantified by $\Delta G = -RT\ln K_{eq}$, was enhanced in direct proportion to the WT/L646E subunit ratio, indicating full cooperativity among subunits. A similar mode of interaction between WT and mutant subunits in concatenated tetramers was previously reported for the activation and block by TEA of Kv1.1 channels (Hurst et al., 1992). The $V_{0.5}$ for activation of Kv1.1 was shifted to more positive potentials as a linear function of the number of subunits containing a L305I mutation, and the free energy of binding of TEA was linearly related to the number of subunits containing Tyr379 (a residue in the outer pore which mediates high-affinity TEA binding). These results derive from cooperative subunit interactions and not from positive cooperativity of drug binding to multiple sites on a single channel.

Similar to many oligomeric enzymes (Monod et al., 1965), multimeric ion channels have the capacity to mediate homotropic cooperative interactions. For example, potentiation of pentameric $\alpha 7$ nicotinic receptors by the type II–positive allosteric modulator PNU-120596, caused by slowing of channel desensitization, is mediated by highly cooperative subunit interactions. At least four and perhaps five of the available PNU-120596–binding sites must be occupied to achieve maximal channel activation (daCosta and Sine, 2013). In contrast, activation of the same receptors by the native ligand acetylcholine involves independent subunit interactions. Occupancy of only one of the five available binding sites by acetylcholine is sufficient to fully activate $\alpha 7$ nicotinic receptors (Andersen et al., 2013). Thus, subunit interaction can vary widely depending on the ligand used to interrogate channel function. We examined the effects of two hERG1 agonists with different mechanisms of action but with overlapping binding sites. Both PD and ICA bind to a hydrophobic pocket located between two adjacent hERG1 subunits, and thus, a homotetrameric channel has four identical binding sites. The ability of PD to increase current magnitude, quantified by $\Delta G = -RT\ln K_{eq}$, was enhanced in direct proportion to the WT/L646E subunit ratio, indicating full cooperativity among subunits. A similar mode of interaction between WT and mutant subunits in concatenated tetramers was previously reported for the activation and block by TEA of Kv1.1 channels (Hurst et al., 1992). The $V_{0.5}$ for activation of Kv1.1 was shifted to more positive potentials as a linear function of the number of subunits containing a L305I mutation, and the free energy of binding of TEA was linearly related to the number of subunits containing Tyr379 (a residue in the outer pore which mediates high-affinity TEA binding). These results derive from cooperative subunit interactions and not from positive cooperativity of drug binding to multiple sites on a single channel.

Figure 9. Attenuation of hERG1 inactivation by ICA exhibits positive cooperativity. (A) Representative current traces under control conditions and after 10 µM ICA for tetramers containing the indicated number and orientation of WT and F557L subunits. (B) Normalized $I_{test}$-$V_{t}$ relationships for concatenated tetramers measured in the presence of 30 µM ICA ($n = 4-10$). Currents were normalized to the peak $I_{test}$ under control conditions for each channel type. Symbol legends refer to data plotted in B, C, and G. (C) Correlation between log fold increase in $I_{test}$ at 20 mV induced by 30 µM ICA and the number of WT subunits (i.e., number of functional ICA binding sites) in a concatenated tetramer. Data were fitted with a linear function: $y = 0.36x + 0.1$ ($R^2 = 0.94$). (D) Fully activated $L_{test}$-$V_{rel}$ relationship for FL1/WT3 and FL1/WT3/FL2 tetramers before and after 30 µM ICA ($n = 4$). Currents were normalized to control $I_{test}$ at −120 mV. (E) Voltage dependence of inactivation for FL1/WT3 and FL1/WT3/FL2 tetramers before and after 30 µM ICA ($n = 4$). $V_{0.5_{inact}}$ and $z$ values are presented in Table 2. (F) Effect of 30 µM ICA on the fully activated $L_{test}$-$V_{rel}$ relationships for WT1 channel currents recorded from oocytes bathed in a solution containing 20 mM KCl ($n = 4$). Data were normalized to control $I_{test}$ at −120 mV under control conditions. (G) Plot of calculated energy values, $\Delta G = k_{FV_{0.5_{inact}}}^{test}$ (30µM ICA) − $k_{FV_{0.5_{inact}}}$ (control), versus number of WT subunits contained in a concatenated tetramer compared with the relationships predicted for independent subunit transitions (--) and cooperative subunit interactions, models 1 (A) and 2 (B). Data are expressed as mean ± SEM ($n =$ number of oocytes). Standard errors in $k_{FV_{0.5_{inact}}}$ were calculated as described previously (Yifrach and MacKinnon, 2002).
indicate that each of the four subunits in a WT channel contributes equally to the formation of the TEA-binding site and to the voltage dependence of channel activation (Hurst et al., 1992). Analysis of the rate and voltage dependence of activation of Shaw/Shaker heterodimer channels also indicates cooperative subunit interactions, and the total energy associated with channel opening is approximated by assuming that ∆G for each subunit type was additive (Smith-Maxwell et al., 1998). A full complement of concatenated tetramers incorporating WT subunits or mutant subunits (containing G466P to disrupt the S6 gating hinge) was also used to characterize subunit cooperativity in the activation of Shaker channels (Zandany et al., 2008). It was found that a single G466P subunit in any position of the tetramer caused the same negative shift in the voltage dependence of activation (∆∆G ≈ 6 kcal/mol), as was achieved with all other heterotypic tetramers or the tetramer containing all mutant subunits. Thus, in contrast to other S4 segment mutations used to probe for subunit cooperativity (Hurst et al., 1992; Smith-Maxwell et al., 1998), a mutation that directly disrupts the gating hinge (G466P) provides a direct demonstration that activation of Kv channels requires all-or-none (i.e., fully concerted) participation of subunits to open the activation gate.

Subunit cooperativity has also been described for C-type inactivation of Kv channels (Ogielska et al., 1995; Panyi et al., 1995), a gating process which prevents K+ flux, either by constriction (Yellen et al., 1994) or dilation (Hoshi and Armstrong, 2013) of the narrowest region of the channel pore formed by the selectivity filter. Although C-type inactivation is very slow and voltage independent in Shaker (Kv1) channels (Hoshi et al., 1991), it is extremely fast and voltage dependent in hERG1 (Kv11.1) channels (Smith et al., 1996; Spector et al., 1996). C-type inactivation of hERG1 can also be disrupted by mutation of specific residues in or near the selectivity filter (e.g., G628C/S631C; Smith et al., 1996) or pore helix (e.g., S620T; Ficker et al., 1998). ICA-mediated shifts in the voltage dependence of C-type inactivation of hERG1 also involve subunit cooperativity. ∆∆G calculated from the differences between steady-state inactivation curves before and after ICA was a nonlinear function of the number of WT subunits (i.e., available ICA binding sites), indicating a more complex mode of cooperativity than reported for C-type inactivation of Kv1.3 channels probed with a point mutation (A413V) that accelerates inactivation (Panyi et al., 1995). Each A413V-containing subunit was shown to contribute equally (approximately 0.6 kcal/mol) to the activation free energy for transitions between O and I states.

In summary, construction and characterization of concatenated heterotetrameric channels have revealed the stoichiometry of allosteric alteration of channel gating by hERG1 agonists. Increased P0, by PD and inhibition of C-type inactivation by ICA involve subunit cooperativity, and occupancy of all four available binding sites is required for maximal effect of both compounds. A detailed understanding of how these and other compounds allosterically modify selectivity filter gating should aid rational design of drugs that can be used to prevent arrhythmias associated with inherited and acquired long QT syndrome.
