POTENTIALS FOR ELLIPTIC BOUNDARY VALUE PROBLEMS IN CONES

VLADIMIR VASILYEV

Abstract. We consider an elliptic pseudo differential equation in a multi-dimensional cone and starting wave factorization concept we add some boundary conditions. For the simplest cases explicit formulas for solution are given like layer potentials for classical case.

Key words and phrases: pseudo differential equation, wave factorization, boundary value problem, cone, layer potential

MSC2010: 35S15, 47G40

1. Introduction

How potentials are constructed for boundary value problems? One takes a fundamental solution of corresponding differential operator in whole space \( \mathbb{R}^m \), and with its help constructs the potentials according to boundary conditions. Further, one studies their boundary properties, and with the help of potentials reduces the boundary value problem to an equivalent integral equation on the boundary. The formulas for integral representation of solution of the boundary value problem one has for separate cases only (ball, half-space, such places, where one has explicit form for Green function). Thus, an ideal result for boundary value problem even with smooth boundary is its reduction to equivalent Fredholm equation and obtaining the existence and uniqueness theorem (without knowing how the solution looks) [1, 2, 3, 4, 5]. I would like to show, that potentials can arise from another point of view, without using fundamental solution, but using factorization idea and they obviously must take into account the boundary geometry. Smooth boundary is locally a hyper-plane (there is Poisson formula for the Dirichlet problem, see also [6]), first type of non-smooth boundary is conical surface [7].

1 This work was completed when the author was a DAAD stipendiat and hosted in Institute of Analysis and Algebra, Technical University of Braunschweig.
2. Preliminaries

Let’s go to studying solvability of pseudo differential equations \([7, 9, 10]\)
\[
(1) 
(Au_+)(x) = f(x), \ x \in C^a_+, 
\]
in the space \(H^s(C^a_+)\), where \(C^a_+\) is \(m\)-dimensional cone \(C^a_+ = \{ x \in \mathbb{R}^m : x = (x_1, ..., x_{m-1}, x_m), x_m > a|x'|, a > 0 \}, \ x' = (x_1, ..., x_{m-1})\), \(A\) is pseudo differential operator \((\tilde{u} denotes the Fourier transform of \(u))\)
\[
u(x) \mapsto \int_{\mathbb{R}^m} e^{ix \cdot \xi} A(\xi) \tilde{u}(\xi) d\xi, \ x \in \mathbb{R}^m,
\]
with the symbol \(A(\xi)\) satisfying the condition
\[
c_1 \leq |A(\xi)(1 + |\xi|)^{-\alpha}| \leq c_2.
\]
(Such symbols are elliptic \([6]\) and have the order \(\alpha \in \mathbb{R}\) at infinity.)

By definition, the space \(H^s(C^a_+)\) consists of distributions from \(H^s(\mathbb{R}^m)\), which support belongs to \(C^a_+.\) The norm in the space \(H^s(C^a_+)\) is induced by the norm from \(H^s(\mathbb{R}^m).\) The right-hand side \(f\) is chosen from the space \(H_0^{-\alpha}(C^a_+)\), which is space of distributions \(S'(C^a_+)\), admitting the continuation on \(H^{s-\alpha}(\mathbb{R}^m).\) The norm in the space \(H_0^{-\alpha}(C^a_+)\) is defined
\[
||f||^+_s = \inf ||lf||_{s-\alpha},
\]
where infimum is chosen from all continuations \(l\).

Further, let’s define a special multi-dimensional singular integral by the formula
\[
(G_m u)(x) = \lim_{\tau \to 0^+} \int_{\mathbb{R}^m} \frac{u(y', y_m) dy' dy_m}{(|x' - y'|^2 - a^2(x_m - y_m + i\tau)^2)^{m/2}}
\]
(we omit a certain constant, see \([7]\)). Let us recall, this operator is multi-dimensional analogue of one-dimensional Cauchy type integral, or Hilbert transform.

We also need some notations before definition.

The symbol \(C^a_+^*\) denotes a conjugate cone for \(C^a_+:\)
\[
C^a_+^* = \{ x \in \mathbb{R}^m : x = (x', x_m), ax_m > |x'| \},
\]
\(C^-_+ \equiv -C^a_+, \ T(C^a_+)\) denotes radial tube domain over the cone \(C^a_+,\) i.e. domain in a complex space \(\mathbb{C}^m\) of type \(\mathbb{R}^m + iC^a_+.\)

To describe the solvability picture for the equation \((1)\) we will introduce the following
Definition. Wave factorization for the symbol $A(\xi)$ is called its representation in the form

$$A(\xi) = A_\neq(\xi)A_\equiv(\xi),$$

where the factors $A_\neq(\xi), A_\equiv(\xi)$ must satisfy the following conditions:

1) $A_\neq(\xi), A_\equiv(\xi)$ are defined for all admissible values $\xi \in \mathbb{R}^m$, without may be, the points $\{\xi \in \mathbb{R}^m : |\xi'|^2 = a^2\xi_m^2\}$;

2) $A_\neq(\xi), A_\equiv(\xi)$ admit an analytical continuation into radial tube domains $T(C^a_+), T(C^a_-)$ respectively with estimates

$$|A^{\pm 1}_\neq(\xi + i\tau)| \leq c_1(1 + |\xi| + |\tau|)^{\pm \alpha},$$

$$|A^{\pm 1}_\equiv(\xi - i\tau)| \leq c_2(1 + |\xi| + |\tau|)^{\pm (\alpha - \alpha)}, \forall \tau \in C^a_\pm.$$

The number $\alpha \in \mathbb{R}$ is called index of wave factorization.

The class of elliptic symbols admitting the wave factorization is very large. There are the special chapter in the book [7] and the paper [8] devoted to this question, there are examples also for certain operators of mathematical physics.

Everywhere below we will suppose that the mentioned wave factorization does exist, and the sign $\sim$ will denote the Fourier transform, particularly $\tilde{H}(\mathcal{D})$ denotes the Fourier image of the space $H(\mathcal{D})$.

3. Scheme in details

Now we will consider the equation (1) for the case $\alpha - s = n + \delta, n \in \mathbb{N}, |\delta| < 1/2$, only. A general solution can be constructed by the following way. We choose an arbitrary continuation $lf$ of the right-hand side on a whole space $H^{s-\alpha}(\mathbb{R}^m)$ and introduce

$$u_-(x) = (lf)(x) - (Au_+)(x).$$

After wave factorization for the symbol $A(\xi)$ with preliminary Fourier transform we write

$$A_\neq(\xi)\tilde{u}_+(\xi) + A^{\equiv -1}_\equiv(\xi)\tilde{u}_-(\xi) = A^{\equiv -1}_\equiv(\xi)\tilde{lf}(\xi).$$

One can see that $A^{\equiv -1}_\equiv(\xi)\tilde{lf}(\xi)$ belongs to the space $\tilde{H}^{s-\alpha}(\mathbb{R}^m)$, and if we choose the polynomial $Q(\xi)$, satisfying the condition

$$|Q(\xi)| \sim (1 + |\xi|)^n,$$

then $Q^{-1}(\xi)A^{\equiv -1}_\equiv(\xi)\tilde{lf}(\xi)$ will belong to the space $\tilde{H}^{-\delta}(\mathbb{R}^m)$. 
Further, according to the theory of multi-dimensional Riemann problem \cite{7}, we can decompose the last function on two summands (jump problem):

\[ Q^{-1}A_\pm^{-1}\tilde{t}f = f_+ + f_-, \]

where \( f_+ \in \tilde{H}(C_+^a) \), \( f_- \in \tilde{H}(R^m \setminus C_+^a) \).

So, we have

\[ Q^{-1}A_\pm \tilde{u}_+ + Q^{-1}A_\pm^{-1}\tilde{u}_- = f_+ + f_-, \]

or

\[ Q^{-1}A_\pm \tilde{u}_+ - f_+ = f_- - Q^{-1}A_\pm^{-1}\tilde{u}_- \]

In other words,

\[ A_\pm \tilde{u}_+ - Qf_+ = Qf_- - A_\pm^{-1}\tilde{u}_-. \]

The left-hand side of the equality belongs to the space \( \tilde{H}^{-n-\delta}(C_+^a) \), and right-hand side is from \( \tilde{H}^{-n-\delta}(R^m \setminus C_+^a) \), hence

\[ F^{-1}(A_\pm \tilde{u}_+ - Qf_+) = F^{-1}(Qf_- - A_\pm^{-1}\tilde{u}_-), \]

where the left-hand side belongs to the space \( H^{-n-\delta}(C_+^a) \), and the right-hand side belongs to the space \( H^{-n-\delta}(R^m \setminus C_+^a) \), that’s why we conclude immediately that it is distribution supported on \( \partial C_+^a \).

The main tool now is to define the form of the distribution.

Let’s denote \( T_a \) the bijection operator transferring \( \partial C_+^a \) into hyperplane \( x_m = 0 \), more precisely, it is transformation \( R^m \rightarrow R^m \) of the following type

\[
\begin{align*}
  t_1 &= x_1, \\
  \cdots \cdots \\
  t_{m-1} &= x_{m-1}, \\
  t_m &= x_m - a|x'|.
\end{align*}
\]

Then the function

\[ T_a F^{-1}(A_\pm \tilde{u}_+ - Qf_+) \]

will be supported on the hyperplane \( t_m = 0 \) and belongs to \( H^{-n-\delta}(R^m) \).

Such distribution is a linear span of Dirac mass-function and its derivatives \cite{11} and looks as the following sum

\[
\sum_{k=0}^{n-1} c_k(t')\delta^{(k)}(t_m).
\]

It is left to think, what is operator \( T_a \) in Fourier image. Explicit calculations give simple answer:

\[ F T_a u = V_a \tilde{u}, \]
where \( V_a \) is something like a pseudo differential operator with symbol 
\( e^{-ia|\xi'|\xi_m} \), and further one can construct the general solution for our pseudo differential equation (1).

We need some connections between the Fourier transform and the operator \( T_a \):

\[
(F Tu)(\xi) = \int_{\mathbb{R}^m} e^{-ix\cdot\xi} u(x_1, \ldots, x_{m-1}, x_m - a|x'|) dx = \\
= \int_{\mathbb{R}^m} e^{-iy'\cdot\xi'} e^{-i(y_m+a|y'|)\xi_m} u(y_1, \ldots, y_{m-1}, y_m) dy = \\
= \int_{\mathbb{R}^{m-1}} e^{-ia|y'|\xi_m} e^{-iy'\cdot\xi'} \hat{u}(y_1, \ldots, y_{m-1}, \xi_m) dy',
\]

where \( \hat{u} \) denotes the Fourier transform on the last variable, and Jacobian is

\[
\frac{D(x_1, x_2, \ldots, x_m)}{D(y_1, y_2, \ldots, y_m)} = \begin{vmatrix}
1 & 0 & \cdots & 0 & 0 \\
0 & 1 & \cdots & 0 & 0 \\
0 & 0 & \cdots & 1 & 0 \\
\frac{\alpha_{y_1}}{|y'|} & \frac{\alpha_{y_2}}{|y'|} & \cdots & \frac{\alpha_{y_{m-1}}}{|y'|} & 1
\end{vmatrix} = 1.
\]

If we define a pseudo differential operator by the formula

\[
(Au)(x) = \int_{\mathbb{R}^m} e^{ix\cdot\xi} A(\xi) \hat{u}(\xi) d\xi,
\]

and the direct Fourier transform

\[
\hat{u}(\xi) = \int_{\mathbb{R}^m} e^{-ix\cdot\xi} u(x) dx,
\]

then we have the following relation formally at least

\[
(F Tu)(\xi) = \int_{\mathbb{R}^{m-1}} e^{-ia|y'|\xi_m} e^{-iy'\cdot\xi'} \hat{u}(y_1, \ldots, y_{m-1}, \xi_m) dy.
\]

In other words, if we denote the \((m-1)\)-dimensional Fourier transform \((y' \to \xi' \text{ in distribution sense})\) of function \( e^{-ia|y'|\xi_m} \) by \( E_a(\xi', \xi_m) \), then the formula (2) will be the following

\[
(F Tu)(\xi) = (E_a * \hat{u})(\xi),
\]

where the sign * denotes a convolution for the first \( m-1 \) variables, and the multiplier for the last variable \( \xi_m \). Thus, \( V_a \) is a combination
of a convolution operator and the multiplier with the kernel \( E_a(\xi', \xi_m) \). It is very simple operator, and it is bounded in Sobolev-Slobodetskii spaces \( H^{s}(\mathbb{R}^m) \).

Notice that distributions supported on conical surface and their Fourier transforms were considered in [11], but the author didn’t find the multi-dimensional analogue of theorem on a distribution supported in a single point in all issues of this book.

**Remark 1.** One can wonder why we can’t use this transform in the beginning to reduce the conical situation (1) to hyper-plane one, and then to apply Eskin’s technique [6]. Unfortunately, it’s impossible, because \( T_a \) is non-smooth transformation, but even for smooth transformation we obtain the same operator \( A \) with some additional compact operator. Obtaining the invertibility conditions for such operator is a very serious problem.

4. General solution

The following result is valid (it follows from considerations of Sec.3).

**Theorem.** A general solution of the equation (1) in Fourier image is given by the formula

\[
\tilde{u}_+(\xi) = A^{-1}_\mp(\xi)Q(\xi)G_mQ^{-1}(\xi)A^{-1}_\pm(\xi)\tilde{f}(\xi) + \\
+ A^{-1}_\mp(\xi)V_{-a}F \left( \sum_{k=1}^{n} c_k(x')\delta^{(k-1)}(x_m) \right),
\]

where \( c_k(x') \in H^{sk}(\mathbb{R}^{m-1}) \) are arbitrary functions, \( s_k = s - \alpha + k - 1/2, \ k = 1, 2, \ldots, n \), \( \tilde{f} \) is an arbitrary continuation of \( f \) on \( H^{s-\alpha}(\mathbb{R}^m) \).

Starting this representation one can suggest different statements of boundary value problems for the equation (1).

5. Boundary conditions: simplest variant, the Dirichlet condition

Let’s consider a very simple case, when \( f \equiv 0, \ a = 1, \ n = 1 \). Then the formula from theorem takes the form

\[
\tilde{u}_+(\xi) = A^{-1}_\mp(\xi)V_{-1}\tilde{c}_0(\xi').
\]

We consider the following construction separately. According to the Fourier transform our solution is

\[
u_+(x) = F^{-1}\{A^{-1}_\mp(\xi)V_{-1}\tilde{c}_0(\xi')\}.
\]

Let’s suppose we choose the Dirichlet boundary condition on \( \partial C^1_+ \) for unique identification of an unknown function \( c_0 \), i.e.

\[(Pu)(y) = g(y),\]
where \( g \) is given function on \( \partial C_1^+ \), \( P \) is restriction operator on the boundary, so we know the solution on the boundary \( \partial C_1^+ \).

Thus,
\[
T_1 u(x) = T_1 F^{-1}\{A_{\neq}^{-1}(\xi)V_{-1}\tilde{c}_0(\xi')\},
\]
so we have
\[
(3) \quad FT_1 u(x) = F(T_1 F^{-1}\{A_{\neq}^{-1}(\xi)V_{-1}\tilde{c}_0(\xi')\}) = V_1\{A_{\neq}^{-1}(\xi)V_{-1}\tilde{c}_0(\xi')\},
\]
and we know \( (P'T_1 u)(x') \equiv v(x') \), where \( P' \) is the restriction operator on the hyperplane \( x_m = 0 \).

The relation between the operators \( P' \) and \( F \) is well-known [6]:
\[
(FP'u)(\xi') = \int_{-\infty}^{+\infty} \tilde{u}(\xi', \xi_m)d\xi_m.
\]

Returning to the formula (3) we obtain the following
\[
(4) \quad \tilde{v}(\xi') = \int_{-\infty}^{+\infty} \{V_1\{A_{\neq}^{-1}(\xi)V_{-1}\tilde{c}_0(\xi')\}\}(\xi', \xi_m)d\xi_m,
\]
where \( \tilde{v}(\xi') \) is given function. Hence, the equation (4) is an integral equation for determining \( c_0(x') \).

The Neumann boundary condition leads to analogous integral equation (see below).

6. Conical potentials

Let's consider the particular case: \( f \equiv 0 \), \( n = 1 \). The formula for general solution of the equation (1) takes the form
\[
\tilde{u}_+(\xi) = A_{\neq}^{-1}(\xi)V_{-1}F\{c_0(x')\delta(0)(x_m)\},
\]
and further after Fourier transform (for simplicity we write \( \tilde{c} \) instead of \( \tilde{c}_0(\xi') \))
\[
(5) \quad \tilde{u}_+(\xi) = A_{\neq}^{-1}(\xi)\tilde{c}(\xi'),
\]
or equivalently the solution is the following
\[
u_+(x) = F^{-1}\{A_{\neq}^{-1}(\xi)\tilde{c}(\xi')\}.
\]

Then we apply the operator \( T_\alpha \) to formula (5)
\[
(T_\alpha u_+)(t) = T_\alpha F^{-1}\{A_{\neq}^{-1}(\xi)\tilde{c}(\xi')\}
\]
and the Fourier transform
\[
(FT_\alpha u_+)(\xi) = FT_\alpha F^{-1}\{A_{\neq}^{-1}(\xi)\tilde{c}(\xi')\}.
\]
If the boundary values of our solution \( u_+ \) are known on \( \partial C^a_+ \), it means that the following function is given
\[
\int_{-\infty}^{+\infty} (FT_a u_+)(\xi) d\xi_m.
\]
So, if we denote
\[
\int_{-\infty}^{+\infty} (FT_a u_+)(\xi) d\xi_m \equiv \tilde{g}(\xi'),
\]
then for determining \( \tilde{c}(\xi') \) we have the following equation
\[
\int_{-\infty}^{+\infty} (FT_a F^{-1}) \{A_{\xi}^{-1}(\xi)\tilde{c}(\xi')\} d\xi_m = \tilde{g}(\xi'),
\]
This is a convolution equation, and if evaluating the inverse Fourier transform \( \xi' \to x' \), we’ll obtain the conical analogue of layer potential.

6.1. **Studying the last equation.** Now we’ll try to determine the form of the operator \( FT_a F^{-1} \) (see above Sec. 3). We write
\[
(FT_a F^{-1} \hat{u})(\xi) = (FT_a u)(\xi) = \int_{\mathbb{R}^{m-1}} e^{-ia|y'|}\xi_m e^{-iy' \cdot \xi'} \hat{u}(y', \xi_m) dy',
\]
where \( y' = (y_1, ... y_{m-1}) \), \( \hat{u} \) is the Fourier transform of \( u \) on last variable \( y_m \).

Let’s denote the convolution operator with symbol \( A_{\xi}^{-1}(\xi) \) by letter \( a \), so that by definition
\[
(a * u)(x) = \int_{\mathbb{R}^m} a(x - y) u(y) dy,
\]
or, for Fourier images,
\[
F(a * u)(\xi) = A_{\xi}^{-1}(\xi) \hat{u}(\xi).
\]
As above let’s denote \( \hat{a}(x', \xi_m) \) the Fourier transform of convolution kernel \( a(x) \) on the last variable \( x_m \). The integral in (6) takes the form (according to (7))
\[
\int_{\mathbb{R}^{m-1}} e^{-ia|y'|}\xi_m e^{-iy' \cdot \xi'} (\hat{a} * c)(y', \xi_m) dy',
\]
POTENTIALS FOR ELLIPTIC BOUNDARY VALUE PROBLEMS IN CONES

Taking into account the properties of convolution operator and the Fourier transform we have the following representation (see Sec.3)

\[ E_a * (A_{\neq}^{-1}(\xi)\tilde{c}(\xi')) , \]

or, enlarged notice,

\[ \int_{R^{m-1}} E_a(\xi' - \eta', \xi_m) A_{\neq}^{-1}(\eta', \xi_m)\tilde{c}(\eta')d\eta'. \]

Then the equation (6) will take the following form respectively

(8) \[ \int_{R^{m-1}} K_a(\eta', \xi' - \eta')\tilde{c}(\eta')d\eta' = \tilde{g}(\xi'), \]

where

\[ K_a(\eta', \xi') = \int_{-\infty}^{+\infty} \frac{E_a(\xi', \xi_m)}{A_{\neq}(\eta', \xi_m)}d\xi_m. \]

So, the integral equation (8) is an equation for determining \( \tilde{c}(\xi') \). This is a conical analogue of the double layer potential.

Let’s suppose we solved this equation and constructed the inverse operator \( L_a \), so that \( L_a\tilde{g} = \tilde{c} \). By the way we’ll note the unique solvability condition for the equation (8) (i.e. existence of bounded operator \( L_a \)) is necessary and sufficient for unique solvability for our Dirichlet boundary value problem. Using the formula (5) we obtain

\[ \tilde{u}_+(\xi) = A_{\neq}^{-1}(\xi)(L_a\tilde{g})(\xi'), \]

or renaming,

\[ \tilde{u}_+(\xi) = A_{\neq}^{-1}(\xi)\tilde{d}_a(\xi'). \]

Then,

(9) \[ u_+(x', x_m) = \int_{R^{m-1}} W(x' - y', x_m)d_a(y')dy', \]

where \( W(x', x_m) = F_{\xi\rightarrow x}(A_{\neq}^{-1}(\xi)) \).

The formula (9) is an analogue of Poisson integral for a half-space.

7. COMPARISON WITH HALF-SPACE CASE FOR THE LAPLACIAN

For the half-space \( x_m > 0 \) we have the following (see Eskin’s book [6]):

\[ \tilde{u}_+(\xi) = \frac{\tilde{c}(\xi')}{\xi_m + i|\xi'|}. \]
If we have the Dirichlet condition on the boundary, it means, that the function
\[
\tilde{g}(\xi') = \int_{-\infty}^{+\infty} \tilde{u}_+(\xi) d\xi_m
\]
is given.

From formula above we have
\[
\tilde{g}(\xi') = \tilde{c}(\xi') \int_{-\infty}^{+\infty} \frac{d\xi_m}{\xi_m + i|\xi'|},
\]
and we need to calculate the last integral only.

For this case we can use the residue technique and obtain, that the last integral is equal to \(-\pi i\).

Thus,
\[
\tilde{u}_+(\xi) = -\frac{\tilde{g}(\xi')}{{\pi i}(\xi_m + i|\xi'|)}.
\]

Consequently, our solution \(u_+(x)\) is the convolution (for first \((m-1)\) variables) of the given function \(g(x')\) and the kernel defined by inverse Fourier transform of function \((\xi_m + i|\xi'|)^{-1}\) (up to constant). The inverse Fourier transform on variable \(\xi_m\) leads to the function \(e^{-x_m|\xi'|}\), and further, the inverse Fourier transform \(\xi' \rightarrow x'\) leads to Poisson kernel
\[
P(x', x_m) = \frac{c_m x_m}{(|x'|^2 + x_m^2)^{m/2}},
\]
c\(_m\) is certain constant defined by Euler \(\Gamma\)-function.

Thus, for the solution of the Dirichlet problem in half-space \(\mathbb{R}^m_+\) for the Laplacian with given Dirichlet data \(g(x')\) on the boundary \(\mathbb{R}^{m-1}\) we have the following integral representation
\[
u_+(x', x_m) = \int_{\mathbb{R}^{m-1}} P(x' - y', x_m) g(y') dy'.
\]

8. Oblique derivative problem

Let’ go back to formula (5). We can write
\[
\xi_k \tilde{u}_+(\xi) = \xi_k A_{\neq}^{-1}(\xi) \tilde{c}(\xi),
\]
or equivalently according to Fourier transform properties
\[
\frac{\partial u_+}{\partial x_m} = F^{-1}\{\xi_k A_{\neq}^{-1}(\xi) \tilde{c}(\xi)\},
\]
for arbitrary fixed \(k = 1, 2, \ldots, m\).
Further, we apply the operator $T_a$ and work as above. Our considerations will be the same, and in all places instead of $A^{-1}_\neq(\xi)$ will stand $\xi_k A^{-1}_\neq(\xi)$.

I call this situation the oblique derivative problem, because $\frac{\partial}{\partial x_k}$ related to conical surface is not normal derivative exactly.

**Remark 2.** Some words on Neumann problem. If we try to give normal derivative of our solution on conical surface different from origin, then we have the boundary value problem with variable coefficients because the boundary condition varies from one point to another one on conical surface. We need additional localization for such points to reduce it to the case of constant coefficients and consider corresponding model problem in $\mathbb{R}^m$. Roughly speaking, I would like to say, that the solution looks locally different in dependence on the type of boundary point. In other words, local principle permits to work with symbols and boundary conditions non-depending on space variable.

**9. Conclusions**

It seems to solve explicitly the simplest boundary value problems in domains with conical point we need to use another potentials different from classical simple and double layer potentials. I will try to show this fact for the Laplacian with Dirichlet condition on conical surface in my forthcoming paper by direct calculations.

**Acknowledgements.** Many thanks to DAAD and Herr Prof. Dr. Volker Bach for their support.
