Background: Human papillomavirus (HPV) is a major risk factor for cervical cancer. Methods: We evaluated the clinical significance of the HPV DNA chip genotyping assay (MyHPV chip, Mygene Co.) compared with the Hybrid Capture 2 (HC2) chemiluminescent nucleic acid hybridization kit (Digene Corp.) in 867 patients. Results: The concordance rate between the MyHPV chip and HC2 was 79.4% (kappa coefficient, $\kappa = 0.55$). The sensitivity and specificity of both HPV tests were very similar (approximately 85% and 50%, respectively). The addition of HPV result (either MyHPV chip or HC2) to cytology improved the sensitivity (95%, each) but reduced the specificity (approximately 30%, each) compared with the HPV test or cytology alone. Based on the MyHPV chip results, the odds ratio (OR) for ≥high-grade squamous intraepithelial lesions (HSILs) was 9.9 in the HPV-16/18 (+) group and 3.7 in the non-16/18 high-risk (HR)-HPV (+) group. Based on the HC2 results, the OR for ≥HSILs was 5.9 in the HR-HPV (+) group. When considering only patients with cytological diagnoses of “negative for intraepithelial lesion or malignancy” and “atypical squamous cell or atypical glandular cell,” based on the MyHPV chip results, the ORs for ≥HSILs were 6.8 and 11.7, respectively, in the HPV-16/18 (+) group. Conclusions: The sensitivity and specificity of the MyHPV chip test are similar to the HC2. Detecting HPV-16/18 with an HPV DNA chip test, which is commonly used in many Asian countries, is useful in assessing the risk of high-grade cervical lesions.

Key Words: Human papillomavirus; DNA chip; Hybrid capture 2; Cervical intraepithelial neoplasia; Cervical carcinoma
grade squamous intraepithelial lesions (HSILs).

MATERIALS AND METHODS

Study subjects

This study was approved by the Institutional Review Board of The Catholic University of Korea, Seoul St. Mary’s Hospital, and complied with the tenets of the Declaration of Helsinki. We retrospectively reviewed the pathology archive database records of 867 consecutive gynecological patients treated at Seoul St. Mary’s Hospital, from January 2006 to December 2009, for whom cervical cytology and HPV test results from both the HC2 and MyHPV chip were available and confirmed by histological examination. The majority of patients were referred to our institution due to abnormal results in routine cervical examinations, and thus the patients underwent cervical cytology, HPV test (HC2 to confirm HPV infection and MyHPV chip to determine infected HPV genotype), and colposcopic examinations followed by tissue biopsy if necessary. The cervical cytology, HC2 test, and MyHPV chip tests were simultaneously performed on the same sample in most cases. Otherwise, we selected cytology that was performed within 2 weeks prior to HPV testing. We classified cervical cytology according to the 2001 Bethesda System for Reporting Cervical Cytology. The diagnoses of all included patients were pathologically confirmed by biopsy, conization and/or hysterectomy within 3 months of cervical cytology and HPV testing. The patients were divided based on age as follows: ≤ 29 years, 178 patients (20.5%); 30–39 years, 281 patients (32.4%); 40–49 years, 243 patients (28.0%); 50–59 years, 109 patients (12.6%); and ≥ 60 years, 56 patients (6.5%); the mean age was 40 years.

HPV genotyping using the MyHPV chip test

The MyHPV chip test contains probes for 15 HR (HPV-16, -18, -31, -33, -35, -39, -45, -51, -52, -53, -56, -58, -59, -66, and -68) and 9 low-risk HPV types (HPV 6, 11, 34, 40, 42, 43, 44, 54, and 70). The MyHPV chip test was performed according to the manufacturer’s instructions under the supervision of Dr. A. Lee (pathologist with a specialty in gynecopathology and molecular pathology). The cervical DNA was isolated from specimens and amplified using polymerase chain reaction (PCR) with consensus GP5+/GP6+ primers. Beta-globin was amplified as an internal control. The PCR product (5 μL) was subjected to 2.5% agarose gel electrophoresis. Twenty-four type-specific 30-mer oligonucleotide probes containing an amine group at the 5’ terminus were immobilized onto a slide glass chip. The PCR products were labelled with Cy5-dUTP, denatured, mixed with hybridization solution, and incubated on the DNA chip. The hybridized HPV DNA was visualized using a DNA chip scanner (ScanArray LITE, GSI Lumonics Inc., Bedford, MA, USA). Clearly visualized double-positive spots for a specific HPV type were considered “specific HPV-positive.” Samples negative on the chip scanner but positive for the 150-bp HPV-specific band using gel electrophoresis were interpreted as “negative for 15 HR-HPV and nine low-risk HPV types but positive for other HPV types.” A lack of visualized spots and samples negative for the 150-bp HPV-specific band using gel electrophoresis were considered “HPV-negative.”

HC2 DNA hybridization assay

The HC2 test was performed according to the manufacturer’s instructions as previously described. In brief, the specimens for the HC2 test were denatured and hybridized with RNA probes to detect 13 HR-HPV types (HPV-16, -18, -31, -33, -35, -39, -45, -51, -52, -56, -58, -59, and -68) in a microplate format. These hybrids react with multiple antibody conjugates and are quantified based on an amplified chemiluminescent signal. Relative light units/positive control values ≥ 1.00 were considered “positive,” whereas values < 1.00 were considered “negative.”

Statistical analysis

The concordance rates of the MyHPV chip and HC2 were evaluated using the kappa coefficient (κ) with 95% confidence intervals (CIs). The sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) of the MyHPV chip and HC2 for ≥ HSILs were determined using standard statistical tests. The age-adjusted odds ratios (ORs) for ≥ HSILs with 95% CI were evaluated for different categories of MyHPV chip and HC2 results with a binary logistic regression using the SPSS ver. 22.0 software (IBM Co., Armonk, NY, USA). To analyze the MyHPV chip results, patients with single or multiple samples positive for 15 HR genotypes were categorized as HR-HPV (+). Patients with HPV-16 (+) and/or HPV-18 (+) were categorized as HPV-16/18 (+), irrespective of the presence of any other HPV genotypes. Patients with HPV-16 (–) and HPV-18 (–), 13 other HR-HPV (+) with or without low-risk HPV (+) or “HPV-other types” (+) were categorized as non-16/18 HR-HPV (+). Patients with low-risk HPV (+), “HPV-other types” (+) or HPV (–) were categorized as HR-HPV (–). In cases of multiple infections, patients were classified based on the HPV genotypes associated with a higher risk of invasive cancer. For example, a patient with HPV-16 (+) and HPV-31 (+)
was allocated to the HPV-16/18 (+) group.

**RESULTS**

HPV, cytology, and histology test results

Among 867 patients, 575 (66.3%) were HR-HPV (+) according to the MyHPV chip test, 540 (62.3%) were HR-HPV (+) according to the HC2 test, and 545 (62.9%) were classified as atypical squamous cells of undetermined significance (ASCUS) or worse (≥ ASCUS) cytology. The following cytological diagnoses were made for 867 patients: 322 patients were negative for intraepithelial lesion or malignancy (NILM), 138 patients exhibited ASCUS, six patients exhibited atypical glandular cells (AGC), 30 patients exhibited atypical squamous cells for which HSILs (ASC-H) cannot be excluded, 183 patients exhibited low-grade squamous intraepithelial lesions (LSILs), 123 patients exhibited HSILs, including carcinoma in situ, and 65 patients exhibited invasive cancer, including squamous cell carcinoma and adenocarcinoma (Table 1). The overall prevalence rates of histology confirmed HSIL or worse (≥ HSIL) according to the cytological diagnosis of NILM, ASCUS, LSIL, ASC-H, HSIL, and invasive cancer were 12.4%, 25.4%, 24.0%, 60.0%, 83.7%, and 98.4%, respectively. The overall prevalence rates of ≥ HSIL according to the MyHPV chip test for HPV-16/18 (+), non-16/18 HR-HPV (+), and HR-HPV (-) were 58.1%, 36.0%, and 13.0%, respectively. The overall prevalence rates of ≥ HSIL according to the HC2 test for HR-HPV (+) and HR-HPV (-) were 48.3% and 13.5%, respectively (Tables 1, 2).

Clinical performance of the cytology, the MyHPV chip and the HC2

The concordance rate between the MyHPV chip test and the HC2 test was 79.4% (688/867), with a κ-value of 0.551 (Table 3).

chip test, 229 cases (84.2%) were also HR-HPV (+) based on HC2 test. The sensitivity, specificity, PPV, and NPV of the cytology, HC2 and MyHPV chip for ≥HSIL histology were evaluated and found similar among the tests (Table 4). The clinical performance of cytology and HC2 as well as cytology and the MyHPV chip were then evaluated (Table 4). The addition of either HPV test (HC2 or HPV DNA) to cytology for detecting ≥HSIL histology improved the sensitivity and NPV, but reduced the specificity and PPV compared with the HPV test or cytology alone.

Table 4. Clinical performance of cytology, HPV DNA chip test, and HC2 test

| Cytology | HPV DNA chip | HC2 | Cytology + HC2 | Cytology + HPV DNA chip |
|----------|--------------|-----|----------------|-------------------------|
| Sensitivity | 0.869 | 0.875 | 0.856 | 0.954 | 0.951 |
| Specificity | 0.502 | 0.452 | 0.504 | 0.379 | 0.304 |
| PPV | 0.486 | 0.464 | 0.483 | 0.455 | 0.426 |
| NPV | 0.876 | 0.87 | 0.865 | 0.938 | 0.919 |

HPV, human papillomavirus; HC2, Hybrid Capture 2; PPV, positive predictive value; NPV, negative predictive value.

Table 5. Age-adjusted odds ratio for ≥HSILs according to the MyHPV chip and HC2 results

| Cytology | HPV test | Total | ≥HSIL | Odds ratio | 95% CI | p-value |
|----------|----------|-------|-------|------------|--------|---------|
| NILM | HPV DNA chip | HR-HPV (-) | 186 | 15 (8.1) | 2.119 | 0.667–6.995 | 0.217 |
| | | Non-16/18 HR-HPV (+) | 69 | 7 (10.1) | 1.000 | 0.999–1.000 | 1.000 |
| | | HPV-16/18 (+) | 67 | 18 (26.9) | 6.756 | 2.114–21.588 | 0.000 |
| HPV HC2 | | HR-HPV (-) | 227 | 14 (6.2) | 1.000 | 0.996–1.004 | 0.999 |
| | | HR-HPV (+) | 95 | 26 (27.4) | 5.894 | 2.852–12.180 | 0.000 |
| ASC or AGC | HPV DNA chip | HR-HPV (-) | 52 | 6 (11.5) | 1.000 | 0.996–1.003 | 0.999 |
| | | Non-16/18 HR-HPV (+) | 59 | 13 (22.0) | 2.454 | 0.819–7.353 | 0.190 |
| | | HPV-16/18 (+) | 63 | 35 (55.6) | 11.715 | 4.101–33.463 | 0.000 |
| HPV HC2 | | HR-HPV (-) | 50 | 8 (16.0) | 1.000 | 0.996–1.003 | 0.999 |
| | | HR-HPV (+) | 124 | 46 (37.1) | 2.988 | 1.269–7.039 | 0.012 |

≥HSIL, high-grade squamous intraepithelial lesion or worse; HPV, human papillomavirus; NILM, negative for intraepithelial lesion or malignancy; ASC, atypical squamous cells; AGC, atypical glandular cells; CI, confidence interval; HR, high-risk; HC2, Hybrid Capture 2.

We calculated the ORs for ≥HSILs based on the MyHPV chip and HC2 results. The MyHPV chip results were categorized as HPV-16/18 (+), non-16/18 HR-HPV (+), and HR-HPV (–) groups. The age-adjusted ORs for ≥HSIL were 9.9 (95% CI, 6.4 to 15.2) in the HPV-16/18 (+) group and 3.7 (95% CI, 2.4 to 5.7) in the non-16/18 HR-HPV (+) group. Based on HC2 results, the age-adjusted OR for ≥HSIL was 5.9 (95% CI, 4.1 to 8.5) in the HR-HPV (+) group (Table 2). A further subgroup analysis was performed among patients with cytological diagnoses of “NILM” and “atypical squamous cells (ASC) or AGC” (Table 5). Regarding the cytology of “NILM” patients, based on MyHPV chip results, the age-adjusted OR for ≥HSIL in the HPV-16/18 (+) group was 6.8 (95% CI, 2.1 to 21.6), but the OR for ≥HSIL in the non-16/18 HR-HPV (+) group did not significantly differ from the OR in the HR-HPV (–) group. Based on the HC2 results, the age-adjusted OR for ≥HSIL was 5.9 (95% CI, 2.9 to 12.2) in the HR-HPV (+) group (Table 5). Regarding the cytology of “ASC or AGC” patients, based on the MyHPV chip results, the age-adjusted OR for ≥HSIL was 11.7 (95% CI, 4.1 to 33.5) in the HPV-16/18 (+) group, but the OR for ≥HSIL in the
non-16/18 HR-HPV (+) group did not significantly differ from the OR in the HR-HPV (−) group. Based on the HC2 results, the age-adjusted OR for ≥HSIL was 3.0 (95% CI, 1.3 to 7.0) in the HR-HPV (+) group (Table 5).

**DISCUSSION**

HPV-16 and HPV-18 are the main carcinogenic HPV genotypes associated with cervical cancer and are responsible for 55%–60% and 10%–15% of invasive cancers, respectively. Non-16/18 HR-HPV genotypes are associated with 25%–35% of invasive cancers. Because the importance of HPV-16 and HPV-18 in cervical pathology has been sufficiently demonstrated, the updated U.S screening guidelines for the early detection of cervical cancer and its precursors recommend co-testing (cytology in combination with HR-HPV testing) over cytology alone and integrated HPV-16/18 genotyping for the management of patients whose HPV test was positive and cytology negative. Recently, interim guidelines stating that primary HR-HPV testing for cervical cancer screening can be considered an alternative to current U.S cervical screening methods have been published.

In many Asian countries, including Korea, the HPV DNA chip test and PCR-based HPV detection kits as well as the HC2 test are commonly used in clinical settings because the sensitivity and specificity of the HPV DNA chip test and PCR-based HPV detection kits are comparable to the HC2 test for the detection of HSIL or worse disease. The concordance rate between the HPV DNA chip and the HC2 test was previously reported to be 88% (κ = 0.61). In our study, the concordance rate was 79.4% (688/867), with a κ-value of 0.55. The HPV DNA chip exhibits concordance rates ranging from 61.5% and 91.1% compared with DNA sequencing. The wide range of concordance rates for the HPV DNA chip compared with other assays may result from different viral detection thresholds and cross-reactivity. The sensitivity of the HC2 method is subject to a minimum signal detection level, which is the scanner signal:background noise ratio limit at low viral loads, approximately 100 to 1,000 copies.

Additionally, a simple primer set targeting the HPV MY09 region and sequence similarities between the 24 probes of the HPV DNA chip may lead to cross-reactivity that contributes to discordance. In this study, the clinical performance of the MyHPV chip was comparable to HC2 for detecting HSILs or worse. The sensitivity and specificity of both HPV tests and cytology were very similar (approximately 85% and 50%, respectively). Adding the HPV test (MyHPV chip or HC2) to cytology exhibited excellent sensitivity (95%, each) but low specificity (approximately 30%, each). Furthermore, we demonstrated that patients who were HPV-16/18 (+) according to the MyHPV chip were at a higher risk of lesions graded HSIL or worse than patients who were non-16/18 HR-HPV (+) (OR 9.9 vs. 3.7). Among cytology “NILM” and “ASC or AGC” subgroups, the ORs were 5.9 and 3.0, respectively, for patients HR-HPV (+) based on HC2 test, compared with HR-HPV (−) patients. Conversely, patients who tested HR-16/18 positive using the MyHPV chip showed much higher ORs (6.8 and 11.7, respectively). According to these results, clinicians need to refer patients who are HPV-16/18 (+) according to HPV genotyping for immediate colposcopy instead of follow up, even when the cytology test is negative or ambiguous.

We found that patients who were non-16/18 HR-HPV (+) according to the MyHPV chip showed higher risk for ≥HSILs than patients with HR-HPV (−) (OR, 3.7). However, in the subgroup study of cytology “NILM” and “ASC or AGC,” the OR for ≥HSILs in the non-16/18 HR-HPV (+) group did not significantly differ from the HR-HPV (−) group, probably due to the small subgroup population.

The limitations of our study include its retrospective design and that it was conducted at a single institution. Additionally, our patients were primarily referred from local clinics and previously diagnosed as “abnormal” based on local cervical cytology. The overall prevalence rates of ≥HSIL in NILM (12.4%) and ASCUS (25.4%) patients were higher than those reported in a previous study. We hypothesize the cytology may have been under sampled because clinicians tend to forego subsequent extensive sampling if previously diagnosed.

In conclusion, the sensitivity and specificity of the HPV DNA chip test are similar to the HC2 test, and detecting HPV 16/18 with a HPV DNA chip is useful for predicting high-grade cervical lesions. Therefore, the HPV DNA chip genotyping method, which is commonly used in many Asian countries as an HPV DNA test, may be useful in assessing the risk of high-grade cervical lesions.
