A COMBINATORIAL GENERALIZATION OF THE
BOSON-FERMION CORRESPONDENCE

THOMAS LAM

Abstract. We attempt to explain the ubiquity of tableaux and of Pieri and Cauchy formulae for combinatorially defined families of symmetric functions. We show that such formulae are to be expected from symmetric functions arising from representations of Heisenberg algebras. The resulting framework that we describe is a generalization of the classical Boson-Fermion correspondence, from which Schur functions arise. Our work can be used to understand Hall-Littlewood polynomials, Macdonald polynomials and Lascoux, Leclerc and Thibon’s ribbon functions, together with other new families of symmetric functions.

1. Introduction

The classical Boson-Fermion correspondence is an isomorphism between two representations of the Heisenberg algebra $H$: the Bosonic Fock space $K[H_-]$ and the Fermionic Fock space $F^{(0)}$. It identifies the Schur functions $s_\lambda(x_1, x_2, \ldots)$ as the images of the basis of semi-infinite wedges $v_i \wedge v_j \wedge \cdots$ under this isomorphism. The Boson-Fermion correspondence is an important basic result in mathematical physics; see for example [9].

The aim of this article is to replace the classical Fermionic Fock space in the Boson-Fermion correspondence by another representation of the Heisenberg algebra, and to obtain other interesting families of symmetric functions instead of the Schur functions. The symmetric functions that we obtain have a tableaux-like definition, and satisfy both Pieri-like identities and a Cauchy-like identity, which we now explain.

Let $\{F_\lambda(x_1, x_2, \ldots) \in \Lambda_K : \lambda \in S\}$ be a family of symmetric functions with coefficients in a field $K$ (usually $\mathbb{Q}$, $\mathbb{Q}(q)$ or $\mathbb{Q}(q,t)$), where $S$ is some indexing set. Many important families of symmetric functions have the following trio of properties.

1. They can be expressed as the generating functions for a set of “tableaux”, which gives the monomial expansion of $F_\lambda$:

$$F_\lambda(x_1, x_2, \ldots) = \sum_T s(T)x^{\wt(T)},$$

where the sum is over tableaux $T$ with “shape” $\lambda$. The composition $\wt(T)$ is the weight of $T$ and $s(T) \in K$ is some additional parameter associated to $T$. 

Date: July 16, 2005.

The author was supported in part by a Clay Institute Liftoff Fellowship.
(2) Together with a closely related dual family \( \{G_\lambda(x_1, x_2, \ldots) : \lambda \in S\} \) of symmetric functions, they satisfy a Cauchy identity:

\[
\sum_{\lambda \in S} F_\lambda(x_1, x_2, \ldots) G_\lambda(y_1, y_2, \ldots) = \prod_{i,j=1}^{\infty} \left( b_0 + b_1 x_i y_j + b_2 (x_i y_j)^2 + \cdots \right),
\]

where the coefficients \( b_i \in \mathbb{K} \).

(3) They satisfy a Pieri formula:

\[
\tilde{h}_k(x_1, x_2, \ldots) F_\lambda(x_1, x_2, \ldots) = \sum_{\mu \vdash \lambda} b_{\lambda,\mu} F_\mu(x_1, x_2, \ldots),
\]

where \( k \in \mathbb{Z} \) is a positive integer, \( \{\tilde{h}_1, \tilde{h}_2, \ldots\} \in \Lambda_{\mathbb{K}} \) is a sequence of symmetric functions and \( b_{\lambda,\mu} \in \mathbb{K} \) are coefficients for each pair \( \lambda, \mu \) satisfying some condition \( \mu \twoheadrightarrow_k \lambda \).

In all such cases that the author is aware of, the definition of a tableaux involves the condition \( \mu \twoheadrightarrow_k \lambda \) in the Pieri formula. The simplest case is when \( \mathbb{K} = \mathbb{Q} \) and \( F_\lambda = s_\lambda \), the family of Schur functions. The indexing set \( S = \mathcal{P} \) is the set of partitions. The tableaux are usual semi-standard Young tableaux \( T \); the statistic \( s(T) \) is equal to 1 and \( \text{wt}(T) \) is the usual weight associated to \( T \). The dual family \( \{G_\lambda = s_\lambda\} \) is equal to the Schur functions again and in the Cauchy formula, all the coefficients \( b_i = 1 \). In the Pieri formula, \( \tilde{h}_k = h_k \) are the homogeneous symmetric functions. The condition \( \mu \twoheadrightarrow_k \lambda \) is that \( \mu/\lambda \) is a horizontal strip of size \( k \) and all the coefficients \( b_{\lambda,\mu} = 1 \). Recall in particular that a semi-standard Young tableaux is just a chain of partitions forming a sequence of horizontal strips.

Understanding the ubiquity of these three properties in families of symmetric functions was one of the main aims of our work. Our main result is as follows. Given a representation \( V \) of a Heisenberg algebra \( H \) with a distinguished basis \( \{v_s | s \in S\} \), together with a highest vector \( v_0 \) in \( V \), we define a family \( F^V_s(x_1, x_2, \ldots) \) (and a dual family \( G^V_s \)) of symmetric functions which satisfy a generalized Boson-Fermion correspondence. The definition of \( F^V_s \) is tableaux-like: for example it gives the monomial expansion of \( F^V_s \). We show in addition that \( F^V_s \) satisfy a Pieri rule and a Cauchy identity. Examples of symmetric functions that can be obtained in this way include the Schur functions, Schur \( Q \)-functions, Hall-Littlewood functions and Macdonald polynomials; see [16].

The motivating example for us was actually a family \( G_\lambda(x_1, x_2, \ldots; q) \) of \( q \)-symmetric functions defined by Lascoux, Leclerc and Thibon [14] combinatorially via ribbon tableaux and algebraically using the action of the Heisenberg algebra on the Fock space of the quantized affine algebra \( U_q(\widehat{sl}_n) \). In [12] we studied the \( G_\lambda \) in analogy with Schur functions and discovered ribbon Cauchy and Pieri identities. The current work is an attempt to understand this in a more systematic and general framework. As an application, we now give natural generalizations of the functions \( G_\lambda \) to Fock spaces of other types and also to higher level Fock spaces. By our main result, these new symmetric functions satisfy Cauchy and Pieri rules as well, and will be the subject of later work.

Our Pieri and Cauchy formulæ depend heavily on a sequence \( a_i \) of parameters defining the relations of the Heisenberg algebra \( H = H[a_i] \) (see Section 3). On the other hand, as an abstract algebra, the Heisenberg algebra does not depend on the \( a_i \) (as long as they are non-zero). Thus it is not clear immediately which sequences \( a_i \) would lead to an interesting theory of symmetric functions.
Our work is also closely related to more combinatorial work of Fomin [4, 5, 6] and of Bergeron and Sottile [1]. Fomin is mostly concerned with Schensted correspondences and the Cauchy identities while Bergeron and Sottile’s work has led to relations with non-commutative symmetric functions and to Hopf algebras. It seems that an interesting non-commutative version of our theory also exists, though we have not attempted to make this precise in the present article.

It would be most interesting to investigate other families of symmetric functions which arise using our correspondence from other representations of Heisenberg algebras which occur naturally.

We now briefly describe the organization of the rest of the paper. In Section 2, we review the theory of Schur functions and symmetric functions. In Section 3, we describe the classical Boson-Fermion correspondence. In Section 4, we explain how to obtain symmetric functions from representations of Heisenberg algebras. In Section 5, we prove our generalized Boson-Fermion correspondence. In Section 6, we prove Pieri and Cauchy formulae for our families of symmetric functions. In Section 7, we prove a partial converse to the theorems of Sections 5 and 6. In Section 8, we give a series of examples beginning with Schur functions, Macdonald polynomials and the behavior when taking direct sums or tensor products of representations. We then explain the example of Lascoux, Leclerc and Thibon’s ribbon functions studied in [14, 12]. Finally, we explain how to generalise ribbon functions to other types and higher levels, following work of Kashiwara, Miwa, Petersen and Yung [10] and Takemura and Uglov [18].

Acknowledgements. I thank Sergey Fomin for discussions related to this work. This work is part of my Ph.D Thesis at M.I.T., written under the guidance of Richard Stanley.

2. Schur functions

We will follow mostly the notation of [16]. Let $K$ be a field with characteristic 0. Let $\Lambda_K$ denote the ring of symmetric functions over $K$. The ring $\Lambda_K$ should be thought of as the ring of formal power series in countably many variables $x_1, x_2, \ldots$, of bounded degree. If the variable set is important then we write $\Lambda_K(\mathbf{X})$ or $\Lambda_K(\mathbf{Y})$.

We will let $h_1, h_2, \ldots$ denote the homogeneous symmetric functions and $p_1, p_2, \ldots$ denote the power sum symmetric functions. Each of these sets forms a set of algebraically independent generators for $\Lambda_K$.

Let $\mathcal{P}$ denote the set of partitions. Let $\lambda = (\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_l > 0) \in \mathcal{P}$ be a partition. The size $|\lambda|$ of $\lambda$ is equal to $\lambda_1 + \cdots + \lambda_l$ and we write $\lambda \vdash |\lambda|$. We also write $l(\lambda) = l$. We generally do not distinguish between a partition $\lambda$ and its Young diagram $D(\lambda)$. If $D(\mu) \subset D(\lambda)$ then $\lambda/\mu$ is a skew shape with size $|\lambda/\mu| = |\lambda| - |\mu|$.

We let $h_\lambda := h_{\lambda_1} h_{\lambda_2} \cdots h_{\lambda_l}$ and $p_\lambda := p_{\lambda_1} p_{\lambda_2} \cdots p_{\lambda_l}$. The sets $\{h_\lambda : \lambda \in \mathcal{P}\}$ and $\{p_\lambda : \lambda \in \mathcal{P}\}$ are bases of $\Lambda_K$. The homogeneous symmetric functions and the power sum symmetric functions are related by the formula

$$h_n = \sum_{\lambda \vdash n} z_\lambda^{-1} p_\lambda$$

where $z_\lambda = \frac{1^{m_1(\lambda)} m_1(\lambda)! \cdot \cdots \cdot m_i(\lambda)! \cdot \cdots \cdot m_i(\lambda)!}{m_i(\lambda)! m_1(\lambda)! \cdots m_i(\lambda)!}$ and $m_i(\lambda) = |\{j : \lambda_j = i\}|$.

The monomial symmetric functions are denoted $m_\lambda$ and the Schur functions are denoted $s_\lambda$. The Schur functions (and more generally skew Schur functions) are...
the generating functions of Young tableaux:
\begin{equation}
    s_\lambda(x_1, x_2, \ldots) = \sum_T x^{\text{wt}(T)},
\end{equation}
where the sum is over all semistandard Young tableaux \( T \) of shape \( \lambda \). Alternatively, \( s_\lambda = \sum K_{\lambda\mu} m_\mu \) where the Kostka number \( K_{\lambda\mu} \) is equal to the number of semistandard Young tableaux of shape \( \lambda \) and weight \( \mu \). For the purposes of this paper, a Young tableaux \( T \) of shape \( \lambda \) should be thought of as a chain of partitions \( T = (\emptyset = \lambda^0 \subset \lambda^1 \subset \cdots \subset \lambda^l = \lambda) \) such that each skew shape \( \lambda^i/\lambda^{i-1} \) is a horizontal strip. A horizontal strip is a skew shape containing at most one box in each column. The weight of \( T \) is then the composition \( \text{wt}(T) = (|\lambda^1/\lambda^0|, |\lambda^2/\lambda^1|, \ldots, |\lambda^l/\lambda^{l-1}|) \). Similarly a Young tableaux of skew shape \( \lambda/\mu \) is a chain of partitions \( (\mu = \lambda^0 \subset \lambda^1 \subset \cdots \subset \lambda^l = \lambda) \).

The Schur functions satisfy the following Pieri formula, which describes how to write the product of a Schur function and a homogeneous symmetric function in terms of Schur functions:
\begin{equation}
    h_k s_\lambda = \sum_{\mu \rightarrow_k \lambda} s_\mu,
\end{equation}
where here \( \mu \rightarrow_k \lambda \) means that the skew shape \( \mu/\lambda \) is a horizontal strip of size \( k \).

The Schur functions also satisfy the following Cauchy formula, which holds within the ring \( \Lambda_K(X) \otimes_K \Lambda_K(Y) \), which is the completion of the tensor product of two copies of the symmetric functions.
\begin{equation}
\prod_{i,j} \frac{1}{1 - x_i y_j} = \sum_\lambda s_\lambda(x_1, x_2, \ldots) s_\lambda(y_1, y_2, \ldots).
\end{equation}

The ring of symmetric functions \( \Lambda_K \) possesses a bilinear symmetric form \( \langle \cdot, \cdot \rangle : \Lambda_K \times \Lambda_K \rightarrow K \) given by \( \langle s_\lambda, s_\mu \rangle = \delta_{\lambda\mu} \), or alternatively by \( \langle p_\lambda, p_\mu \rangle = \delta_{\lambda\mu} z_\lambda \). This inner product is known as the Hall inner product. If \( f \in \Lambda_K \) then \( f^\perp \in \text{End}(\Lambda_K) \) denotes the linear operator adjoint to multiplication by \( f \). As a particular case \( p_k^\perp = k \frac{\partial}{\partial p_k} \) where the differential operator acts on symmetric functions written as polynomials in the power sum symmetric functions.

3. The classical Boson-Fermion correspondence

Let \( K \) be a field with characteristic 0. The Heisenberg algebra \( H = H[a_i] \) denotes the associative algebra over \( K \) with 1 generated by \( \{ B_k : k \in \mathbb{Z} \setminus \{0\} \} \) satisfying
\[ [B_k, B_l] = l \cdot a_l \cdot \delta_{k,-l}, \]
for some non-zero parameters \( a_l \in K \) satisfying \( a_l = -a_{-l} \). As an abstract algebra, \( H \) does not depend on the choice of the elements \( a_l \), since the generators \( B_k \) can be re-scaled to force \( a_l = 1 \). However, we shall be concerned with representations of \( H \), and some choices of the generators \( B_k \) will be more natural.

Let \( K[H_-] = K[B_{-1}, B_{-2}, \ldots] \) denote the Bosonic Fock space representation of \( H \). The action of the Heisenberg algebra on \( K[B_{-1}, B_{-2}, \ldots] \) is determined by letting \( B_k \) act by multiplication for \( k < 0 \) and setting \( B_k \cdot 1 = 0 \) for \( k > 0 \).

One can identify \( K[B_{-1}, B_{-2}, \ldots] \) with the algebra \( \Lambda_K \) of symmetric functions over \( K \) by identifying \( B_{-k} \) with \( a_k p_k \) for \( k > 0 \). The action of \( H \) on \( \Lambda_K \) is then
Proposition 2.

Lemma 1. Let $k \geq 1$ be an integer and $\lambda$ be a partition. Then

$$B_{-k} B_{\lambda} = k \mu m_k(\lambda) B_{\mu} + B_{\lambda} B_{-k},$$

where $\mu$ is $\lambda$ with one less part equal to $k$. If $m_k(\lambda) = 0$ then the first term is just 0.

If $V$ is a representation of $H$, then a vector $v \in V$ is called a highest weight vector if $B_k \cdot v = 0$ for $k > 0$. The following result is well known. See for example [9, Proposition 2.1].

Proposition 2. Let $V$ be an irreducible representation of $H$ with non-zero highest weight vector $v \in V$. Then there exists a unique isomorphism of $H$-modules $\phi : V \to K[B_{-1}, B_{-2}, \ldots]$ such that $\phi(v) = 1$.

For the remainder of this section we assume that $H = H[1]$ is given by the parameters $a_l = 1$ for $l \geq 1$ and $a_l = -1$ for $l \leq -1$. Let $W = \bigoplus_{j \in \mathbb{Z}} K v_j$ be an infinite-dimensional vector space with basis $\{v_j : j \in \mathbb{Z}\}$. Let $F^{(0)}$ denote the vector space with basis given by semi-infinite monomials of the form $v_{i_0} \wedge v_{i_1} \wedge \cdots$ where the indices satisfy:

(i) $i_0 > i_{-1} > i_{-2} > \cdots$  
(ii) $i_k = k$ for $k$ sufficiently small.

We will call $F^{(0)}$ the Fermionic Fock space.

Remark 1. Usually $F^{(0)}$ is considered a subspace of a larger space $F = \bigoplus_{m \in \mathbb{Z}} F^{(m)}$. The spaces $F^{(m)}$ are defined as for $F^{(0)}$ with the condition (ii) replaced by the condition (ii$^{(m)}$): $i_k = k - m$ for $k$ sufficiently small.

Define an action of $H$ on $F^{(0)}$ by

$$B_k \cdot (v_{i_0} \wedge v_{i_1} \wedge \cdots) = \sum_{j \leq 0} v_{i_0} \wedge v_{i_1} \wedge \cdots \wedge v_{i_j} \wedge \cdots \wedge v_{i_k} \wedge v_{i_{k+1}} \wedge \cdots.$$  

The monomials are to be reordered according to the usual exterior algebra commutation rules so that $v_{i_0} \wedge \cdots \wedge v_{i_j} \wedge v_{i_{j+1}} \wedge \cdots = -v_{i_0} \wedge \cdots \wedge v_{i_{j+1}} \wedge v_{i_j} \wedge \cdots$. Thus the sum on the right hand side of (5) is actually finite so the action is well defined. One can check that we indeed do obtain an action of $H$. It is also not hard to see that the representation of $H$ on $F^{(0)}$ is irreducible.

The vector $\bar{v} = v_0 \wedge v_{-1} \wedge \cdots \in F^{(0)}$ is a highest weight vector for this action of $H$. By Proposition 2 there exists an isomorphism $\sigma : F^{(0)} \to \Lambda_K$ sending $\bar{v} \mapsto 1$.

An algebraic version of the Boson-Fermion correspondence identifies the image of $v_{i_0} \wedge v_{i_1} \wedge \cdots$ under the isomorphism $\sigma$.

Theorem 3 ([9, Lecture 6]). Let $\lambda_k = i_{-k} + k$. Then $\sigma(v_{i_0} \wedge v_{i_1} \wedge \cdots) = s_{\lambda}$.  

In [9], this is called the “second” part of the boson-fermion correspondence. It is important in the study of a family of non-linear differential equations known as the Kadomtzev-Petviashvili (KP) Hierarchy. The “first” part consists of identifying
the image of certain vertex operators under $\sigma$. The relationship between vertex operators and symmetric function theory have been studied previously in \cite{7,8,16}.

Our aim will be to generalise Theorem \ref{thm:main} to representations of Heisenberg algebras with arbitrary parameters $a_i \in K$. We will see that the symmetric functions that one obtains in this manner will always have a tableaux-like definition and satisfy Pieri and Cauchy identities. In our approach, we have ignored the vertex operators, but it would be interesting to see how they are related to our results.

4. Symmetric functions from representations of Heisenberg algebras

Let $H = H[a_i]$ be the Heisenberg algebra with parameters $a_i \in K$. Define $B_\lambda := B_{\lambda_1}B_{\lambda_2}\cdots B_{\lambda_{(\lambda)}}$. Let $D_k := \sum \lambda^{-k} z^\lambda B_{\lambda}$ and $U_k := \sum \lambda^{-k} z^\lambda B_{-\lambda}$ where $z_\lambda$ is as defined in Section \ref{sec:2}. Thus $B_\lambda$ and $D_k$ are related in the same way as $p_\lambda$ and $h_k$ (see \ref{eq}).

Similarly define $B_{-\lambda} := B_{-\lambda_1}B_{-\lambda_2}\cdots B_{-\lambda_{(\lambda)}}$ and $U_k := \sum \lambda^{-k} z^\lambda B_{-\lambda}$. Also let $S_\lambda \in H$ be given by $S_\lambda := \sum \mu z^{-1}_\mu \chi^\lambda_\mu B_{\mu}$ where the coefficients $\chi^\lambda_\mu$ are the characters of the symmetric group given by $s_\lambda = \sum \mu z^{-1}_\mu \chi^\lambda_\mu p_\mu$.

Let $V$ be a representation of $H$ with distinguished basis $\{v_s : s \in S\}$ for some indexing set $S$. For simplicity we will assume that both $V$ and $S$ are $\mathbb{Z}$-graded so that $v_s \in V$ are homogeneous elements and $\deg(v_s) = \deg(s)$, and that each graded component of $V$ is finite-dimensional. We will also assume that the action of $H$ is graded in the sense that $\deg(B_k) = -mk$ for some $m \in \mathbb{Z}\setminus\{0\}$. Define an inner product $\langle \cdot, \cdot \rangle : V \times V \rightarrow K$ on $V$ by requiring that $\{v_s | s \in S\}$ forms an orthonormal basis, so that $\langle v_s, v_{s'} \rangle = \delta_{ss'}$.

Let $s, t \in S$. Define the generating functions

\begin{equation}
F_{s/t}^V(x_1, x_2, \ldots) = F_{s/t}(x_1, x_2, \ldots) := \sum_\alpha x^\alpha \langle U_{\alpha_1}U_{\alpha_{i-1}} \cdots U_{\alpha_1} \cdot t, s \rangle,
\end{equation}

where the sum is over all compositions $\alpha = (\alpha_1, \alpha_2, \ldots, \alpha_l)$. Similarly define

\begin{equation}
G_{s/t}^V(x_1, x_2, \ldots) = G_{s/t}(x_1, x_2, \ldots) := \sum_\alpha x^\alpha \langle D_{\alpha_1}D_{\alpha_{i-1}} \cdots D_{\alpha_1} \cdot s, t \rangle.
\end{equation}

Note that $F_{s/t}$ and $G_{s/t}$ are homogeneous with degree $\frac{\deg(s) - \deg(t)}{m}$. So in particular if $\deg(s) - \deg(t)$ is negative or non-integral then the generating functions are 0. For convenience we let $U_\alpha := U_{\alpha_1}U_{\alpha_{i-1}} \cdots U_{\alpha_1}$ and $D_\alpha := D_{\alpha_1}D_{\alpha_{i-1}} \cdots D_{\alpha_1}$.

The above definitions should be thought of as a tableaux-like definition, as the following example explains.

Example 4 (Schur functions). Let $H[a_i] = H[1]$ and $V = \mathcal{F}(0)$. Set $S = P$ and $v_\lambda := v_{i_0} \wedge v_{i_{-1}} \wedge \cdots$, where $\lambda_k = i_{-k} + k$. Then we have

\[ U_k \cdot v_\lambda = \sum_{\mu \prec \lambda} v_\mu, \]

where the sum is over all horizontal strips $\mu/\lambda$ of size $k$. So the definition \ref{eq} of $F_{s/t}$ reduces to \ref{eq} – the combinatorial definition of skew Schur functions in terms of Young tableaux.

The following Proposition is immediate from the definition, since $U_k$ commutes with $U_l$ and $D_k$ commutes with $D_l$ for all $k, l \in \mathbb{N}$.

Proposition 5. The generating functions $F_{s/t}$ and $G_{s/t}$ are symmetric functions.
As before, let $K[H_-] \subset H$ denote the subalgebra of $H$ generated by $\{B_k \mid k < 0\}$ and similarly define $K[H_+] \subset H$. The definitions of $F_{s/t}$ and $G_{s/t}$ can be rephrased in terms of the Heisenberg-Cauchy elements $\Omega(H_-,X)$ and $\Omega(H_+,X)$ which lie in the completed tensor products $K[H_-] \hat{\otimes} \Lambda_K(X)$ and $K[H_+] \hat{\otimes} \Lambda_K(X)$ respectively:

$$\Omega(H_-,X) := \sum_\lambda U_\lambda \otimes m_\lambda = \sum_\lambda z_\lambda^{-1} B_{-\lambda} \otimes p_\lambda = \sum_\lambda S_\lambda \otimes s_\lambda.$$ 

The last two equalities follow from the classical Cauchy identity. Also define $v$ given by

$$H \rightarrow v \mapsto \sum_{\lambda \vdash m} \frac{H^\lambda}{S_\lambda} v_s \cdot \frac{1}{m!} \frac{H^\lambda}{S_\lambda} v_t,$$

for $v = \sum_{\lambda \vdash m} \frac{H^\lambda}{S_\lambda} v_s \cdot \frac{1}{m!} \frac{H^\lambda}{S_\lambda} v_t$. The symmetry functions $F_s$ are the coefficients of $\Omega(H_-,X) \cdot v_b$ when it is written in the basis $\{v_s \mid s \in S\}$:

$$\Omega(H_-,X) \cdot v_b = \sum_s v_s \otimes F_s(x_1, x_2, \ldots).$$

5. Generalization of Boson-Fermion correspondence

Let us suppose that $b \in S$ has been picked so that $v_b \in V$ is a highest weight vector for $H$. We will write $F_s := F_s/b$ and $G_s := G_s/b$. The element $\Omega(H_-,X) \cdot v_b \in V \hat{\otimes} \Lambda_K(X)$ depends only on the choice of $v_b$. The symmetric functions $F_s$ are the coefficients of $\Omega(H_-,X) \cdot v_b$ when it is written in the basis $\{v_s \mid s \in S\}$:

$$\Omega(H_-,X) \cdot v_b = \sum_s v_s \otimes F_s(x_1, x_2, \ldots).$$

Theorem 6 (Generalized Boson-Fermion correspondence). The map $\Phi : V \rightarrow \Lambda_K$ given by $v_s \mapsto G_s(x_1, x_2, \ldots)$ is a map of $H$-modules.

Recall that $B_{-k}$ acts on $\Lambda_K$ by multiplication by $a_k p_k$ and $B_k$ acts as $k \frac{\partial}{\partial p_k}$, for $k \geq 1$.

Proof. Let us calculate $B_l \cdot G_s$ and compare with $\Phi(B_l \cdot v_s)$. Suppose first that $l < 0$ and let $k = -l$. Let $\mu$ be a partition and let $\mu$ be $\lambda$ with one less part equal to $k$. If $\lambda$ has no part equal to $k$, then $\mu$ can be any partition in the following formulae. First write $\langle B_{\lambda} B_l \cdot v_s, v_{\lambda} \rangle = k a_k m_k(\lambda) \langle B_{\lambda} v_s, v_{\lambda} \rangle$, using a slight variation of Lemma 4 for our $H$. Alternatively, one can also compute

$$B_{\lambda} B_l \cdot v_s = B_{\lambda} \sum_c \langle B_{l} \cdot v_s, v_c \rangle v_c = \sum_c \langle B_l \cdot v_s, v_c \rangle \langle B_{\lambda} \cdot v_c, v_{\lambda} \rangle v_d$$

so that taking the coefficient of $v_b$ we obtain

$$ka_k m_k(\lambda) \langle B_{\mu} \cdot v_s, v_{\lambda} \rangle = \sum_c \langle B_l \cdot v_s, v_c \rangle \langle B_{\lambda} \cdot v_c, v_{\lambda} \rangle.$$
Now, 
\[ B_l \cdot G_s = a_k p_k G_s \]
\[ = a_k \sum_{\mu} z_{\mu}^{-1} p_k p_{\mu} \langle B_{\mu} \cdot v_s, v_b \rangle \]
\[ = \sum_{\lambda} z_{\lambda}^{-1} p_{\lambda} \left( \sum_c \langle B_l \cdot v_s, v_c \rangle \langle B_{\lambda} \cdot v_c, v_b \rangle \right) \]
\[ = \sum_c \langle B_l \cdot v_s, v_c \rangle \left( \sum_{\lambda} z_{\lambda}^{-1} \langle B_{\lambda} \cdot v_c, v_b \rangle \right) \]
\[ = \sum_c \langle B_l \cdot v_s, v_c \rangle G_c. \]

This shows that \( \Phi(B_l \cdot v_s) = B_l \cdot \Phi(v_s) \) for \( l < 0 \).

Now suppose \( k > 0 \), and let \( \lambda \) and \( \mu \) be related as before. Then 
\[ B_k \cdot G_s = k \sum_{\lambda} z_{\lambda}^{-1} \frac{\partial}{\partial p_k} p_{\lambda} \langle B_{\lambda} \cdot v_s, v_b \rangle \]
\[ = k \sum_{\lambda} z_{\lambda}^{-1} m_k(\lambda)p_{\mu} \langle B_{\mu} B_k \cdot v_s, v_b \rangle \]
\[ = \sum_{\mu} z_{\mu}^{-1} p_{\mu} \langle B_{\mu} \cdot \sum_c \langle B_k \cdot v_s, v_c \rangle v_c, v_b \rangle \]
\[ = \sum_c \langle B_k \cdot v_s, v_c \rangle \left( \sum_{\mu} z_{\mu}^{-1} p_{\mu} \langle B_{\mu} \cdot v_c, v_b \rangle \right) \]
\[ = \sum_c \langle B_k \cdot v_s, v_c \rangle G_c. \]

This completes the proof. \( \square \)

When \( V \) is irreducible, the map \( \Phi \) does not depend on the choice of basis, but does depend on \( v_b \). Since the degree \( \deg(v_b) \) part of \( V \) is one dimensional, the image of \( v \in V \) is given by the coefficient of the degree \( \deg(v_b) \) part of \( \Omega(H, X) \cdot v \).

If \( V \) is not irreducible then the map depends on the inner product \( \langle \cdot, \cdot \rangle \) of \( V \) (or equivalently, the choice of orthonormal basis).

Note that a different action of \( H \) on \( \Lambda_\sigma \) will allow us to replace the family \( G_s \) in Theorem 6 by \( F_s \). More precisely, one can define the adjoint action \( \theta : H \rightarrow \text{End}(V) \) of \( H \) on \( V \) by letting the generators \( B_k \) act according to the formula 
\[ \langle \theta(B_k) \cdot v_s, v_b \rangle = \langle v_s, B_{-k} \cdot v_b \rangle. \]

With this new representation of \( H \) on \( V \), the roles of \( G_s \) and \( F_s \) are reversed.

6. Pieri and Cauchy identities

Let \( h_k[a_i] \) denote the image \( \theta(h_k) \) of \( h_k \) under the algebra homomorphism \( \theta : \Lambda \rightarrow \Lambda_\sigma \) given by \( \theta(p_k) = a_k p_k \). Also let \( h_k[a_i] \) denote the image \( \kappa(h_k) \) of \( h_k \) under the map \( \kappa : \Lambda_\sigma \rightarrow K \) given by \( \kappa(p_k) = a_k \). Note that if all \( \{ a_i | i \geq 1 \} \) are positive (rational) numbers then by 14, so are the numbers \( h_k[a_i] \). Let \( h_k^\perp \) be the linear operator on \( \Lambda_\sigma \) which is adjoint to multiplication by \( h_k \) with respect to the Hall inner product.
The dual identities are:

\[ K \Lambda \]

The following identity holds as elements of Lemma 8.

Theorem 6 and the comments immediately after it. □

Proof. Follows immediately from the definitions of \( U_k, D_k \) and \( h_k[a_i] \) together with Theorem 4 and the comments immediately after it.

Lemma 8. The following identity holds as elements of \( H[a_i] \):

\[ D_b U_a = \sum_{j=0}^{m} h_j \langle a_i \rangle U_{a-j} D_{b-j} , \]

where \( m = \min(a, b) \).

Proof. By definition we need to show that

\[
\left( \sum_{\lambda' \vdash a-j} z^{-1}_\lambda \right) \left( \sum_{\lambda' \vdash b-j} z^{-1}_\lambda \right) = \sum_{j=0}^{m} h_j \langle a_i \rangle \left( \sum_{\lambda' \vdash a-j} z^{-1}_\lambda \right) \left( \sum_{\lambda' \vdash b-j} z^{-1}_\lambda \right) .
\]

Let \( \mu \) and \( \nu \) be partitions such that \( |\mu| = a-j \) and \( |\nu| = b-j \). By (11), the coefficient of \( B_{-\mu} B_{-\nu} \) on the right hand side is equal to \( z^{-1}_\mu z^{-1}_\nu \sum_{\lambda' \vdash \lambda} z^{-1}_\lambda \theta(p_\lambda) \). Let \( \rho = \lambda \cup \mu \) and \( \pi = \lambda \cup \nu \). We claim that the summand \( z^{-1}_\rho z^{-1}_\mu z^{-1}_\nu \theta(p_\lambda) \) is the coefficient of \( B_{-\mu} B_{-\nu} \) when applying \( [B_k, B_l] = k \alpha_k \delta_{k,-l} \) repeatedly to \( z^{-1}_\rho z^{-1}_\mu B_{-\mu} B_{-\nu} \). This is a straightforward computation, counting the number of ways of picking parts from \( \rho \) and \( \pi \) to make the partition \( \lambda \).

□

In fact the relation (12), together with the relations \([U_k, U_l] = [D_k, D_l] = 0\) is equivalent to the defining relations of the Heisenberg algebra \( H[a_i] \). This is because the sets \( \{B_k \mid k \neq 0\} \) and \( \{U_k \mid k \geq 1\} \cup \{D_k \mid k \geq 1\} \) are both generators of \( H[a_i] \).

Theorem 9 (Generalized Cauchy Identity). We have the following identity in the completion of \( \Lambda_K(X) \otimes \Lambda_K(Y) \):

\[
\sum_s F_s(x_1, x_2, \ldots) G_s(y_1, y_2, \ldots) = \prod_{j,k} (1 + h_1 \langle a_i \rangle x_j y_k + h_2 \langle a_i \rangle (x_j y_k)^2 + \cdots). 
\]

More generally, let \( r, t \in S \). Then we have

\[
\sum_s F_{s/t}(x_1, x_2, \ldots) G_{s/r}(y_1, y_2, \ldots) = 
\prod_{j,k} (1 + h_1 \langle a_i \rangle x_j y_k + h_2 \langle a_i \rangle (x_j y_k)^2 + \cdots) \sum_s F_{r/s}(x_1, x_2, \ldots) G_{t/s}(y_1, y_2, \ldots).
\]
Proof. Let \( U(x) := 1 + \sum_{i>0} U_ix^i \) and similarly \( D(x) := 1 + \sum_{i>0} D_ix^i \). The identity of Lemma 1 is equivalent to
\[
D(y)U(x) = U(x)D(y) \left( 1 + h_1(a_i)xy + h_2(a_i)(xy)^2 + \cdots \right).
\]
Now notice that by definition we have \( F_{s/t} = \langle \cdots U(x_3)U(x_2)U(x_1) \cdot v_t, v_s \rangle \) and \( G_{s/t} = \langle \cdots D(x_3)D(x_2)D(x_1) \cdot v_s, v_t \rangle \). The infinite products make sense since in most factors we are picking the term equal to 1. Thus
\[
\sum_s F_{s/t}(x_1, x_2, \ldots)G_{s/t}(y_1, y_2, \ldots) = \langle \cdots D(y_3)D(y_2)D(y_1) \cdots U(x_3)U(x_2)U(x_1) \cdot v_t, v_r \rangle
\]
\[
= \prod_{i,j \geq 1} \left( 1 + h_1(a_i)x_iy_j + h_2(a_i)(x_iy_j)^2 + \cdots \right) \langle \cdots U(x_3)U(x_2)U(x_1) \cdots D(y_3)D(y_2)D(y_1) \cdot v_t, v_r \rangle
\]
\[
= \prod_{i,j \geq 1} \left( 1 + h_1(a_i)x_iy_j + h_2(a_i)(x_iy_j)^2 + \cdots \right) \sum_s G_{t/s}(y_1, y_2, \ldots)F_{t/s}(x_1, x_2, \ldots).
\]
These manipulations of infinite generating functions make sense since they are well defined when restricted to a finite subset of the variables \( \{x_1, x_2, \ldots, y_1, y_2, \ldots\} \).

Remark 2. It is not clear at this moment which sequences \( a_i \) and which representations of \( H[a_i] \) would lead to interesting families of symmetric functions. However, the following may be possible indications:

- Some kind of positivity for the coefficients \( h_i(a_i) \); for example if \( K = \mathbb{Q}(q) \) then we may want \( h_i(a_i) \) to have positive coefficients when expanded as a power series in \( q \).
- A Pieri formula with very few non-zero or with positive coefficients. For example, we may want the coefficients \( \langle U_{k \cdot s}, t \rangle \) and \( \langle D_{k \cdot t}, s \rangle \) to be positive in some sense. This would imply that the definitions of \( F_{t/s} \) and \( G_{t/s} \) would also have a positive monomial expansion.

The results of this Section are related to results of Fomin [1, 3, 5, 6] and of Bergeron and Sottile [11]. Fomin studies combinatorial operators on posets and recovers Cauchy style identities similar to ours. His approach is more combinatorial and he focuses on generalizing Schensted style algorithms to these more general situations. Bergeron and Sottile have also made definitions similar to our \( F_{s/t} \). Their interests have been towards aspects related to Hopf algebras and non-commutative symmetric functions; see also [2, 3].

Remark 3. An interesting non-commutative version of our theory may exist, where the Heisenberg algebra is replaced with an algebra \( A = \langle B_k \mid k \in \mathbb{Z} - \{0\} \rangle \) with relations
\[
[B_k, B_l] = 0 \quad \text{if } k \text{ and } l \text{ have opposite sign and } k \neq -l,
\]
\[
[B_{-k}, B_k] = k a_k.
\]
In this case, the generating functions \( F_{s/t} \) and \( G_{s/t} \) will not be symmetric functions but instead be quasi-symmetric functions.
7. A Partial Converse

A partial converse to Theorems 7 and 9 exists. In other words, if a family of symmetric functions satisfies enough properties, then one can conclude that they arise from a generalized Boson-Fermion correspondence as in Theorem 6.

Let $V$ be a $K$-vector space with a distinguished basis $\{v_s : s \in S\}$. In this section, suppose that $\{B'_k \in \text{End}(V) : k \in \mathbb{Z}\setminus\{0\}\}$ are linear operators acting on $V$. Suppose further that $B_k$ and $B_l$ commute if $k$ and $l$ have the same sign. Let $D'_k := \sum_{\lambda \vdash k} z^{-1}_\lambda B'_\lambda$ and $U'_k := \sum_{\lambda \vdash k} z^{-1}_\lambda B'_\lambda$. Now we can define $F'_{s/t}(x_1, x_2, \ldots) := \sum_{\alpha} x^{\alpha}(U'_1 U'_{a_1-1} \cdot \cdots U'_1 \cdot t, s)$ and similarly for $G'_{s/t}$.

**Theorem 10.** Let $\{a_k \in K \mid k \neq 0\}$ be a sequence of non-zero parameters satisfying $a_k = a_{-k}$ and suppose that $\{G'_s \mid s \in S\}$ are linearly independent. Then the following are equivalent:

1. The operators $\{B'_k\}$ generate an action of the Heisenberg algebra $H[a_i]$ with parameters $a_k$.
2. The family $\{G'_s\}$ satisfies the conclusions of Theorem 7.
3. The families $\{G'_s\}$ and $\{F'_{s/t}\}$ satisfy the conclusions of Theorem 9.

**Proof.** That (1) implies (2) and (3) is Theorems 7 and 9.

Now suppose (2) holds. Since the family $\{G'_s\}$ is linearly independent, the action of $\{U'_k, D'_k\}$ on $V$ is isomorphic to the action of $\{h_k[a_i], h_k^2\}$ on span$_K \{G'_s\}$ under the isomorphism $v_s \mapsto G'_s$. Thus the action of the operators $B'_k$ on $V$ is isomorphic to the action of $\{\theta(p_k), p_k^2\}$ on span$_K \{G'_s\}$ and so generate an action of $H[a_i]$. Thus (2) $\Rightarrow$ (1).

Now suppose (3) holds. Then by the argument in the proof of Theorem 9, we must have

$$(\langle D'(y)U'(x) - U'(x)D'(y) (1 + h_1(a_i)xy + h_2(a_i)(xy)^2 + \cdots) \rangle \cdot v_t, v_r) = 0$$

for every $t, r \in S$. This implies that

$$D'(y)U'(x) = U'(x)D'(y) (1 + h_1(a_i)xy + h_2(a_i)(xy)^2 + \cdots)$$

so that we have

$$D'_k U'_a = \sum_{j=0}^m h_j(a_i) U'_{a-j} D'_{k-j}.$$

Now reversing the argument in the proof of Lemma 8, we deduce that $[B'_k, B'_l] = ka_k \delta_{k,-l}$. So (3) $\Rightarrow$ (1).

8. Examples

8.1. Schur functions. If $K = \mathbb{Q}$ and $V = F^{(0)}$ and $H = H_{\text{Schur}} = H[1]$ acts as in Section 5, then Theorem 6 is just Theorem 3 where the indexing set $S$ can be identified with the set of partitions $\mathcal{P}$. In this case, the operators $B_k$ and $B_{-k}$ are adjoin with respect to $\langle \cdot, \cdot \rangle$ and so $F_{\lambda} = G_{\lambda} = s_\lambda$ for every $\lambda$. The definition of $s_{\lambda/\mu} = F_{\lambda/\mu}$ in terms of the operators $U_k$ is exactly the usual combinatorial definition of skew Schur functions in terms of semistandard Young tableaux. The symmetric function $h_k[a_i] = h_k$ is the usual homogeneous symmetric function and the coefficients $\langle U_k \cdot \lambda, \mu \rangle$ are equal to 1 if $\mu/\lambda$ is a horizontal strip of size $k$ and equal...
to 0 otherwise. The coefficients $h_i(a_i)$ are all equal to 1 and Theorem 9 reduces to the usual Cauchy identity.

8.2. Direct sums. Let $V_1$ and $V_2$ be two representations of $H$ with distinguished bases $\{v_{s_1} : s_1 \in S_1\}$ and $\{v_{s_2} : s_2 \in S_2\}$ respectively. Then $V = V_1 \oplus V_2$ is a representation of $H[a_i]$ with distinguished basis $\{v_s : s \in S_1 \cup S_2\}$. If $s, t \in S_i$ for some $i$ then $F^V_{s/t} = F^{V_i}_{s/t}$ otherwise if for example $s \in S_1$ and $t \in S_2$ we have $F^V_{s/t} = 0$. Thus the family of symmetric functions that we obtain from $H[a_i]$ acting on $V$ is the union of the families of symmetric functions we obtain from $V_1$ and $V_2$.

8.3. Tensor products. Let $V_1$ and $V_2$ be two representations of $H[a_i]$ with distinguished bases $\{v_{s_1} : s_1 \in S_1\}$ and $\{v_{s_2} : s_2 \in S_2\}$ respectively, as before. Then $V_1 \otimes V_2$ has a distinguished basis $\{v_{s_1} \otimes v_{s_2} : s_1 \in S_1$ and $s_2 \in S_2\}$. Let the Heisenberg algebra $\hat{H} := H[b_i]$ with generators $\hat{B}_k$, where $b_i = 2a_i$, act on $V_1 \otimes V_2$ by defining the action of $\hat{B}_k$ by

$$\hat{B}_k \cdot v_1 \otimes v_2 = (B_k \cdot v_1) \otimes v_2 + v_1 \cdot (B_k \cdot v_2).$$

This action is natural when one views $\Lambda_K$ as a Hopf algebra. The action of $\hat{U}_k = \sum_{\lambda \vdash k} z^\lambda \hat{B}_\lambda$ is given by

$$\hat{U}_k \cdot v_1 \otimes v_2 = \sum_{i=0}^k (U_i \cdot v_1) \otimes (U_{k-i} \cdot v_2)$$

and similarly for $\hat{D}_k$. By definition, one sees that $F^{V_1 \otimes V_2}_{s_1 \otimes s_2/t_1 \otimes t_2} = F^{V_1}_{s_1/t_1} \cdot F^{V_2}_{s_2/t_2}$ and similarly for the $G$-functions. Thus the family of symmetric functions we obtain from $V = V_1 \otimes V_2$ are pairwise products of the symmetric functions we obtain from $V_1$ and $V_2$.

More generally, the tensor products $V_1 \otimes \cdots \otimes V_n$ lead to generating functions which are products $F^{V_1}_{s_1/t_1} \cdots F^{V_n}_{s_n/t_n}$ of $n$ original generating functions. We will denote the Heisenberg algebra acting on this tensor product by $H^{(n)} := H[a_i^{(n)}]$. The parameters are given by $a_i^{(n)} = na_i$.

8.4. Macdonald polynomials. Let $K = \mathbb{Q}(q,t)$ and let $P_\lambda(x_1, x_2, \ldots; q,t)$ and $Q_\lambda(x_1, x_2, \ldots; q,t)$ be the Macdonald polynomials introduced in [14]. Let $\lambda = (\lambda_1, \lambda_2, \ldots)$ be a partition and $s = (i, j) \in \lambda$ a square. Then the arm-length of $s$ is given by $a_\lambda(s) = \lambda_i - j$ and the leg-length of $s$ is given by $l_\lambda(s) = \lambda_j - i$. Now let $s$ be any square. Define (14 Chapter VI, (6.20)))

$$b_\lambda(s) = b_\lambda(s; q,t) = \begin{cases} 1 - q^{a_\lambda(s)} & \text{if } s \in \lambda, \\ 1 - q^{a_\lambda(s) + 1} & \text{otherwise.} \end{cases}$$

Now let $\lambda/\mu$ be a horizontal strip. Let $C_{\lambda/\mu}$ (respectively $R_{\lambda/\mu}$) denote the union of columns (respectively rows) that intersect $\lambda - \mu$. Define (14 Chapter VI, (6.24)))

$$\phi_{\lambda/\mu} = \prod_{s \in C_{\lambda/\mu}} \frac{b_\lambda(s)}{b_\mu(s)}$$

and

$$\psi_{\lambda/\mu} = \prod_{s \in R_{\lambda/\mu} \cap C_{\lambda/\mu}} \frac{b_\mu(s)}{b_\lambda(s)}.$$
Let $V_{\text{Mac}}$ denote the vector space over $K$ with distinguished basis labeled by partitions. Define operators $\{U_k, D_k : k \in \mathbb{Z}_{>0}\}$ by:

$$U_k \cdot \lambda = \sum_{\mu} \phi_{\mu/\lambda \mu}, \quad D_k \cdot \lambda = \sum_{\mu} \psi_{\lambda/\mu \mu},$$

where the sums are over horizontal strips of size $|k|$. Then $Q_{\lambda/\mu} = F_{\lambda/\mu}$ and $P_{\lambda/\mu} = G_{\lambda/\mu}$, so in particular the operators $\{U_k \mid k \in \mathbb{Z}_{>0}\}$ commute and so do the operators $\{D_k \mid k \in \mathbb{Z}_{>0}\}$. Now we have (10 Ex.7.6)

$$\sum_{\rho} Q_{\rho/\lambda}(X; q, t) P_{\rho/\mu}(Y; q, t) = \left( \sum_{\sigma} Q_{\mu/\sigma}(X; q, t) P_{\lambda/\sigma}(Y; q, t) \right) \prod_{i,j} \frac{1 - (t^i y_j q^r)}{1 - x_i y_j q^r}.$$

The product $\prod_{i=0}^{\infty} \frac{1 - q^{n+r}}{1 - q^r}$ can be written as $\sum_{n \geq 0} g_n(1, 0, 0, \ldots; q, t) y^n$ where $g_n$ is given by (10 Chapter VI, (2.9))

$$g_n(x_1, x_2, \ldots; q, t) = \sum_{\lambda \vdash n} z_\lambda(q, t)^{-1} p_\lambda(x_1, x_2, \ldots),$$

where $z_\lambda(q, t) = z_\lambda \prod_{i=1}^{(|\lambda|)} \frac{1 - q^{x_i}}{1 - q^{x_i}}$. Using Theorem 10 we see that the operators $\{U_k, D_k \mid k \in \mathbb{Z}_{>0}\}$ generate a copy of a Heisenberg algebra $H_{\text{Mac}}$. A short calculation shows that the parameters $a_k \in \mathbb{Q}(q, t)$ of this Heisenberg algebra are given by $a_k = \frac{1-t^k}{1-q^k}$. The parameters $h_k\langle a_i \rangle$ are given by $h_k\langle a_i \rangle = g_n(1, 0, 0, \ldots; q, t) = \sum_{\lambda \vdash n} z_\lambda(q, t)^{-1}$.

In fact Theorem 10 shows that the Pieri (and dual Pieri) rule for MacDonald polynomials is equivalent to the (generalized) Cauchy identity for Macdonald polynomials.

**Remark 4.** To obtain the Hall-Littlewood functions, one can just specialize $q = 0$ in the set up of this section. However, to obtain the Schur $P$ and $Q$-functions the further specialization $t = -1$ actually causes some of the $a_i$ to be zero. In this case, one should actually consider the subalgebra of the Heisenberg algebra generated by the generators $B_k$ where $k$ is odd.

### 8.5. Ribbon functions

Let $n \geq 1$ be a positive integer and $K = \mathbb{Q}(q)$. In (13), a family of symmetric functions $\{G^{(n)}_\lambda(x_1, x_2, \ldots; q)\}$ defined in terms of ribbon tableaux, called ribbon functions or LLT-polynomials, were introduced. These symmetric functions arise as the polynomials $\{F^F_\lambda(x_1, x_2, \ldots)\}$ for the action of a Heisenberg algebra $H[a_i]$ on the level one Fock space $F$ of $U_q(\mathfrak{sl}_n)$. This Fock space $F$ has a basis $|\lambda\rangle$ naturally labeled by partitions. The parameters are given by $a_i = \frac{1-q^{2n+i}}{1-q^{2n}}$ and the action of $H[a_i]$, commuting with the action of $U_q(\mathfrak{sl}_n)$, was discovered in (11). The actions of the generators $B_{-k}$ and $B_k$ of this Heisenberg algebra are adjoint with respect to the inner product $\langle \lambda, |\mu\rangle = \delta_{\lambda\mu}$, and so the symmetric functions $F_\lambda$ and $G_\lambda$ for this representation of $H[a_i]$ coincide. In (12), a ribbon Cauchy and Pieri formula for the functions $G^{(n)}_\lambda(X; q)$ was deduced from the action of $H[a_i]$ and this is a special (in fact, motivating) case for Theorems 7 and 9.

At $q = 1$, the Fock space $F$ for $U_q(\mathfrak{sl}_n)$ should be thought of as a sum of tensor products:

$$F \cong \bigoplus_{n\text{-cores}} (F^{(0)})^n$$

(10)
where $\mathcal{F}^{(0)}$ is the classical Fermionic Fock space described in Section 3. Combinatorially, the decomposition is given by writing a partition in terms of its $n$-core and its $n$-quotient; see [14]. As shown in subsection 8.3, the $F$-functions we obtain in this way are products of $n$ of the $F$-functions for $\mathcal{F}^{(0)}$, that is, (skew) Schur functions. This is simply the formula $G_\lambda(x_1, x_2, \ldots ; q) = \delta_\lambda(0) \delta_\lambda(1) \cdots \delta_\lambda(n-1)$ observed in [14]. In fact, the $q = 1$ specialization corresponds to action of the Heisenberg algebra commuting with the action of $\hat{\mathfrak{sl}}_n$ on $F$.

It would be interesting to see whether ribbon functions and Macdonald polynomials can be combined by finding a deformation of the action of $(H_{\text{Mac}})^{(n)}$ on $V^{\otimes n}_{\text{Mac}}$.

### 8.6. Ribbon functions for other types and other levels

Theorem 6 allows us to define analogues of LLT’s ribbon functions $G^{(n)}(x_1, x_2, \ldots ; q)$ for other (quantized) Fock spaces.

Kashiwara, Miwa, Petersen and Yung [10] have defined (level one) $q$-deformed Fock spaces for the affine algebras $A^{(1)}_1, A^{(2)}_2, B^{(2)}_n, A^{(2)}_{2n-1}, D^{(1)}_n$ and $D^{(2)}_{n+1}$, using a sophisticated construction involving perfect crystals. Let $\Phi$ denote one of these root systems and let $U_q(\mathfrak{g})$ be the corresponding quantum affine algebra. Let $\mathcal{F}^\Phi$ be the corresponding $q$-deformed Fock space of [10], which is defined over $K = \mathbb{Q}(q)$. The space $\mathcal{F}^\Phi$ is equipped with an action of an Heisenberg algebra $H[a^\Phi]$ commuting with the action of $U_q(\mathfrak{g})$, where the parameters $a^\Phi$ are calculated in [10]. The Fock space $\mathcal{F}^\Phi$ also has a standard basis indexed by certain semi-infinite products of elements from a perfect crystal for $U_q(\mathfrak{g})$. We will call this indexing set $S^\Phi$. There is a distinguished highest weight vector $v_b \in \mathcal{F}^\Phi$ for some “bottom element” $b \in S^\Phi$.

**Definition 11.** Let $s \in S^\Phi$. The ribbon function of type $\Phi$ is given by $G^\Phi_s = F_{s/b}^{\mathcal{F}^\Phi} \in \Lambda_K$.

When $\Phi = A^{(1)}_{n-1}$, we recover LLT’s ribbon functions $G^\Phi = G^{(n)}(x_1, x_2, \ldots ; q)$. The functions $G^{(n)}(x_1, x_2, \ldots ; q)$ have been found to be not only interesting combinatorially (see [12, 14]) but also to be related to the global basis of the Fock space and to Kazhdan-Lusztig polynomials (see [15]). One should expect the symmetric functions $G^\Phi_s$ to be interesting as well. Some work in this direction can be found in [13] and will appear separately. Note that it is not known (but in some cases a conjecture) that the action of the generators $B_k$ and $B_{-k}$ of the Heisenberg algebra on $\mathcal{F}^\Phi$ are adjoint. This would imply that $F_{s/b}^{\mathcal{F}^\Phi} = G_{s/b}^{\mathcal{F}^\Phi}$.

In another direction, Takemura and Uglov [18] have studied Fock spaces $\mathbf{F}^{n,m}$ for the quantum affine algebra $U_q(\mathfrak{sl}_n)$ of level $m$. These Fock spaces also possess a standard basis indexed by partitions and an action of a Heisenberg algebra $H^{n,m}$ commuting with the action of $U_q(\mathfrak{sl}_n)$.

**Definition 12.** Let $\lambda \in \mathcal{P}$. The ribbon function of rank $n$ and level $m$ is given by $G^{(n,m)}_\lambda = F_{\lambda/\emptyset}^{\mathbf{F}^{n,m}} \in \Lambda_K$.

We have placed the parameters $n$ and $m$ together in the notation since as explained in [18] there is a level-rank duality in this Fock space. The case $m = 1$ reduces to LLT’s ribbon functions: $G^{(n,1)}_\lambda = G^{(n)}_\lambda$. One should expect the functions $G^{(n,m)}_\lambda$ to be interesting as well. The parameters $a_i$ for $H^{n,m}$ appear to have not yet been calculated, though there are precise conjectures for their values.
A COMBINATORIAL GENERALIZATION OF THE BOSON-FERMION CORRESPONDENCE
