Abstract

Background: New coronavirus (COVID-19) has a major impact on the individual's physical activity level (PAL). The COVID-19 quarantine outbreak caused a decrease in the PAL. Accordingly, it might also affect the general health and quality of life (QoL). This study aimed to evaluate the relationship between PAL with QoL and general health (GH) among COVID-19 recovered individuals (CRI).

Methods: In this descriptive-analytical study, using the multi-stage (Cluster) sampling techniques, 890 CRI (male (n = 438) and female (n = 452)) were volunteered from different COVID-19 testing centers in Kermanshah province. After filling out the consent form, the PAL, GH, and QoL questionnaires were completed and anthropometric parameters were measured. The PAL was assessed using the international physical activity questionnaire (IPAQ-SF), GH was assessed using the GHQ questionnaire and the QoL was measured by the QoL questionnaire (short-form-SF-12). The independent t-test was used to compare the mean of variables between men and women and the Pearson correlation coefficient test was used to evaluate the relationship between variables using SPSS software version 24 at a significant level of (P ≤ 0.05).

Results: The findings of the present study showed that men and women with COVID-19 had inadequate PAL (876.11±40.23; 739.08±27.02), insufficient GH (50.13±3.1; 54.15±4.28), and poor QoL (22.02±2.28; 19.23±1.87), respectively. The results also showed that men had significantly higher PAL (P=0.035), GH (P=0.047), and QoL (P=0.023) compared to women. Also, the results show that increasing the PAL improves GH and QoL.

Conclusions: Considering the prevalence of COVID-19 and its negative impact on GH and QoL, maintaining adequate PAL can be considered as one of the effective strategies for improving physical and GH, and immune systems, by observing the hygiene protocol.

Introduction

After the identification of the first cases of coronavirus (COVID-19) in December 2019, the disease spread around the world quickly, leading to serious global challenges. However, none have been clinically successful, extensive efforts have been made to discover a vaccine or treatment for COVID-19. Following hygiene principles and maintaining physical distancing (social distancing) seem the best ways to prevent and control COVID-19 (1); which has caused changed behavioral patterns and impeded the daily activity habits [1]. Although these steps may be critical in reducing the prevalence of this disease, they will undoubtedly have long-term consequences on physical and general health (GH) [2, 3]. These adverse health consequences are so significant that they require immediate and comprehensive efforts to prevent and counteract the side effects of the COVID-19 on the quality of life (QoL) and GH of individuals. In Kermanshah province, according to the latest updates from Kermanshah medical university (March 1, 2016), 7,000 cases of infection, 650 dead, 6,450 COVID-19 recovered individuals (CRI). According to the results of studies, the COVID-19 severity is closely related to age and underlying diseases (hypertension,
diabetes, cardiovascular diseases, etc.), which can quickly lead to acute respiratory distress syndrome (ARDS) [4, 5]. Strengthening the immune system is among the approaches to prevent COVID-19 until definitive treatment is found [6]. Immune cells are easily affected by a variety of factors, including diet, hormone activity, and exercise [6, 7]. Regular exercise reduces the risk of non-communicable diseases, and viral and bacterial infections [8, 9]. Exercise promotes persistent improvement of the immune system by creating long-term health, as well as having a profound effect on the phenotypic arrangement and functional capacity of the immune system. The reaction of almost all immune cells in the bloodstream changes during and after exercise [10, 11]. However, impaired exercise routines, and increased stress and anxiety due to the COVID-19 outbreak, staying home restrictions, and quarantines, are not unexpected. These attenuate the immune system; reduce the QoL and GH [12, 13]. Various measures are taken to achieve physical and GH and increase public health, including sports and recreational activities. Studies have shown that participating in various physical and recreational activities has physical and psychological benefits that increase the QoL [14, 15]. According to the results of studies, a sedentary lifestyle increases the risk of developing chronic diseases such as cardiovascular disease, diabetes, and hypertension, which also increases the risk of developing COVID-19 [16, 17].

Having sufficient physical activity (PA) not only reduces the prevalence of physical illnesses, psychological disorders, and QoL, but also infectious diseases. Due to the increased prevalence of COVID-19, and the positive effect of PA on the immune system assessing the physical activity level (PAL) in CRI seems necessary. Therefore, this study aimed to investigate the relationship between PAL with QoL and GH in COVID-19 recovered individuals (CRI) in Kermanshah.

**Methods**

**Study Design**

According to the latest statistics from Kermanshah University of Medical Sciences until early February 2021, a total of 7,000 COVID-19 cases were approved by COVID-19 testing centers. For sampling, Kermanshah city was divided into 5 regions: north, south, east, west, and center. The sample size was estimated at 168 CRI from each testing center in each region. To prevent the possible loss of sample size, 30 more CRI were considered from each region, of which a total of 990 CRI (198 in each region) was randomly selected for the study. The selection method was based on the blocks of each area and the individuals were studied based on the random division of the blocks. After the final investigations, 100 subjects were excluded from the study due to incomplete answers to the questioners, and finally, 890 subjects (438 males and 452 females) were analyzed. Inclusion criteria included: 20–70 years, approved COVID-19, finishing the recovery period of COVID-19 (21 days after COVID-19 test), complete improvement (having no sign or symptoms), and GH. The subjects were informed about the study, the confidentiality of the information, and the purpose of the study.

**Tools**
The data collection tool in this study consists of five self-reported sections from the subjects.

**Demographic Information**

The first section consisted of 7 questions about demographic information including age, sex, height, weight, marital status, employment status, and educational stage.

**COVID-19 Symptoms**

The second part was a self-assessment of COVID-19 symptoms which included 3 categories about COVID-19 symptoms based on the world health organization. The first category included questions about less-common COVID-19 symptoms: bruising and pain, sore throat, diarrhea and vomiting, swelling, headache, loss of smell or taste, skin rash, or pale fingers. The second category was related to questions about common COVID-19 symptoms: fever, dry cough, and fatigue, and the third category was related to questions about serious COVID-19 symptoms; Difficulty breathing or shortness of breath, pain or pressure on the chest, and loss of ability to move or speak.

**PAL**

The PAL was assessed using the short edition of the International Physical Activity Questionnaire (IPAQ-SF). The questionnaire was sent electronically to the T2DP and they were asked to answer all the questions carefully, giving each four days to complete the questionnaire [18]. This questionnaire consisted of 10 questions that were organized into four sections of intense PA, moderate PA, walking, and sitting [19]. The intensity and duration of PA were questioned for a week, and activities lasting more than 10 minutes were recorded [18, 19]. Intense PA includes heavy weight training, prolonged aerobic exercise, intense cycling and running; Moderate PA includes lightweight training, regular steady-state cycling, and tennis; Walking includes walking at home, at work, leisure time walking, and planned walking; And sitting includes the amount of time you spend sitting at home, at work, leisure, reading, watching TV, and meeting friends [20, 21]. The validity and reliability of the questionnaire for the Iranian population have been confirmed by Klishadi et al. (2007) [22]. Based on the scoring method of the IPAQ questionnaire, the individual's PAL during the past week is calculated in terms of met/minute/week; walking intensity was 3.3 METS, moderate PA 4 METS, and intense PA were considered 8 METS. To calculate the total amount of PAL, the amount of walking (METS. min. day), the amount of moderate PA (METS. min. day), and the amount of intense PA (METS. min. day) were measured during the past week [23]. The PAL scores in the range below 3000 were considered as low, between the range of 3000 to 6000 as a moderate, and above 3000 as a high PAL.

**QoL**

The QoL was assessed using the SF-12 that was developed as a shorter alternative to the SF-36, applicable to large-scale health surveys where the application of the longer instrument would be too time-consuming or costly. The SF-12 has 12 questions which are grouped into 8 domains or scales of physical functioning (PF), role limitations due to physical health (PH), bodily pain (BP), GH perception (GHP),
social functioning (SF), role limitations due to emotional problems (RE), vitality (VT), and mental health (MH). These 8 scales could be reduced into 2 summary components of the physical component summary (PCS) and mental component summary (MCS). The SF 12 was adapted and validated to Persian conditions by Rohani et al. [24]. The final score of the SF-12 ranged from 0–100; a higher score, indicating a better QoL.

**GH Questions**

The GHQ-28 questionnaire was used to assess the GH of the subjects. This questionnaire was developed in 1972 by Goldberg for screening mental disease (18). The 28-item model of this questionnaire has four subscales including physical symptoms, anxiety and insomnia, depression, and social functioning, which is a total score of four subscales. These subscales show symptoms: however, not necessarily equivalent to psychological diagnoses (19). Numerous studies have reported good validity and reliability for this questionnaire. In Iran, the validity and reliability of this questionnaire have been confirmed (20, 21).

**Statistical analysis**

The independent t-test was used to compare the mean of variables between men and women, and the Pearson correlation coefficient test was used to evaluate the relationship between variables using SPSS software version 24 at a significant level of (P ≤ 0.05).

**Results**

The results of demographic characteristics, PAL, QoL, and GH are presented in Table 1; According to the results of the present study, the PAL, QoL, and GH in females were lower than in males (Table 1).
Table 1
The demographic characteristics, PAL, QoL, and GH among subjects

| Variable  | Male (n = 438) | Female (n = 452) |
|-----------|---------------|------------------|
| Age (years) | 43.10 ± 12.11 | 41.20 ± 9.08    |
| Height (cm)  | 177.02 ± 8.06 | 167.01 ± 6.04   |
| Weight (kg)   | 83.01 ± 12.02 | 78.04 ± 11.03   |
| BMI (kg/m²)   | 226.49 ± 3.03 | 27.96 ± 4.09    |
| PAL (MET)     | 876.11 ± 40.23 | 739.08 ± 27.02  |
| QoL (Score)   | 22.02 ± 2.28  | 19.23 ± 1.87    |
| GH (Score)    | 50.13 ± 3.11  | 54.15 ± 4.28    |
| Married       | 357 (83.78)   | 385 (85.17)     |
| Single        | 81 (16.22)    | 67 (14.83)      |
| Education rate|               |                  |
| High school   | 84 (19.17 %)  | 80 (17.70 %)    |
| Diploma       | 116 (26.48 %) | 106 (23.45 %)   |
| Associate Degree | 64 (14.62 %) | 66 (14.61 %)   |
| BSc           | 136 (31.05 %) | 157 (34.74 %)   |
| MSc           | 33 (7.54 %)   | 39 (8.62 %)     |
| PhD           | 5 (1.14 %)    | 4 (0.88)        |
| Job Status    |               |                  |
| Employee      | 173 (39.49 %) | 147 (32.53 %)   |
| Unemployed    | 123 (28.08 %) | 191 (42.25 %)   |
| Student       | 99 (22.61 %)  | 82 (18.14 %)    |
| Retired       | 21 (4.80 %)   | 6 (1.32 %)      |
| Part-time     | 22 (5.02 %)   | 26 (5.76 %)     |

Also, Table 2 presented the frequency and percentage of symptoms in CRI in 3 categories (less-common, more-common, and serious symptoms). Based on the results, almost all subjects reported having all of the symptoms in the first (less-common symptoms; 49.09% of men and 44.25% of women) and second categories (common symptoms; 36.53% of men and 41.82% of women). While difficulty breathing was the most reported symptom in the third category (30.14% men and 37.38% women).
Table 2

The frequency and percentage of symptoms of COVID-19

| Categories                                      | Male (438)     | Female (452)  |
|-------------------------------------------------|----------------|--------------|
| Less-common Symptoms                           |                |              |
| Soreness and pain                              | 47 (10.73 %)   | 55 (12.17 %) |
| Sore throat                                     | 40 (9.13 %)    | 37 (8.19 %)  |
| Diarrhea and Vomiting                          | 24 (5.47 %)    | 38 (8.41 %)  |
| Inflation                                       | 8 (1.82 %)     | 12 (2.66 %)  |
| Headache                                        | 76 (17.36 %)   | 79 (17.47 %) |
| Loss of smell or taste                         | 21 (4.80 %)    | 26 (5.75 %)  |
| Pimples or paleness of the fingers and toes    | 7 (1.60 %)     | 5 (1.10 %)   |
| All                                             | 215 (49.09 %)  | 200 (44.25 %)|
| More-Common Symptoms                           |                |              |
| Fever                                           | 106 (24.21 %)  | 122 (26.99 %)|
| Dry cough                                       | 89 (20.32 %)   | 76 (16.81 %) |
| Fatigue                                         | 83 (18.94 %)   | 65 (14.38 %) |
| All                                             | 160 (36.53 %)  | 189 (41.82 %)|
| Serious Symptoms                                |                |              |
| Difficulty breathing                            | 132 (30.14 %)  | 169 (37.38 %)|
| Chest pain or pressure                         | 117 (26.71 %)  | 103 (22.79 %)|
| Losing the Ability to Move or Speak            | 69 (15.75 %)   | 66 (14.60 %) |
| All                                             | 26 (5.94 %)    | 25 (5.53 %)  |
| None                                            | 94 (21.46 %)   | 89 (19.70 %) |

The results of the present study show a significant inverse relationship between the PAL with GH and a significant positive relationship between the PAL and QoL in both men and women who recovered from COVID-19. In other words, increasing the PAL improves the GH and QoL in men and women who recovered from COVID-19 (Table 3).
Table 3
The relationship between the PAL with QoL and GH among subjects

| PAL | Gender | GH     | QoL     |
|-----|--------|--------|---------|
|     | Male   | r=-0.589 | r = 0.792 |
|     |        | P = 0.038 * | P = 0.018 * |
|     | Female | r=-0.685 | r = 0.824 |
|     |        | P = 0.029 * | P = 0.001 * |

*: Significantly relationship with PAL with QoL and GH among subjects; the value is calculated using the Pearson's Correlation Coefficient test.

The results of the independent t-test showed that there is a significant difference in the PAL, GH, and QoL between men and women; Men had higher PAL, GH, and QoL (Fig. 1).

Discussion

This study aimed to investigate the relationship between PAL with QoL and GH among men and women with COVID-19. The results of the present study showed that CRI had inadequate PAL and insufficient levels of GH. The results also indicate a significant inverse relationship between the PAL and GH in CRI; Considering that lower GHQ scores mean better GH. Furthermore, the results of the study showed that with increasing the PAL, GH scores decreased. According to these results, increasing the PAL among CRI can improve the GH of men and women through affecting GH components (physical symptoms, anxiety, insomnia, social dysfunction, and Depression) positively. However, our knowledge of the impact of PA on improving the GH of CRI is limited due to the novelty of the subject; However, in line with the present study, the results of studies conducted on other infectious disease showed that adequate PAL could improve the GH [14, 25]. Besides, the results of the present study showed that COVID-19 recovered men had higher PAL than women; This might probably explain the better GH in men. The results also show a significant association between PAL and GH in CRI. Although the exact mechanism of exercise-induced changes in GH is not fully understood, the effect of exercise in promoting and enhancing GH is clear. The benefits of PA in improving the GH in CRI may be related to exercise-induced improvements in the immune system [26, 27]. In general, it can be concluded that maintaining PAL might have positive effects on the GH.

Which has a profound effect on the oxidative phenotype and functional capacity of the immune system, especially in CRI with underlying diseases (e.g., type 2 diabetes, and cardiovascular disease). The alteration of almost all bloodstream immune cell behavior during and after exercise is well established (14). According to studies, the positive effect of regular exercise on chronic inflammation-related diseases is due to the reduction of abdominal fat and obesity and the subsequent anti-inflammatory effects [28].
On one hand, it increases the immune vaccine response, reduces the number of worn and aged T cells [29], increased T cell proliferation, decreased circulating inflammatory cytokines levels, increased neutrophil phagocytic activity, increased cytotoxic activity, and increased the production of muscle cytokines such as IL-12 [29, 30]. On the other hand, one of the theoretical models for psychosocial changes (relief or relaxation) due to PA is probably the activation of the central nervous system and the secretion of endorphins. Pierce (1999) stated that PA increases basal metabolic rate, improves blood circulation throughout the body, uses excess calories, and improves mood by releasing endorphins [31]. Also, Vickers et al (2006) believed that patients are more prone to depression that prevents them from engaging in PA [32]. Additionally, due to the widespread prevalence of COVID-19 worldwide, group PA is not possible, so CRI are suggested to include home-based exercise in their daily routine to improve their GH as well as immune system by increasing their PAL.

The results of the present study also showed a positive and significant relationship between the PAL and QoL among patients with COVID-19 (men and women). In other words, an increase in the QoL was observed with increasing the PAL in CRI. The results also showed a significant difference between QoL among men and women. In comparison to women, the higher PAL in men is probably one of the reasons for the higher QoL in COVID-19 recovered men. However, it should be noted that both COVID-19 recovered men and women had poor QoL. Consistent with the results of the present study, studies have shown that exercise increases the QoL, especially in vulnerable people [33, 34]. One of the possible mechanisms of the effect of exercise on improving the QoL of CRI is to reduce stress, and anxiety [35]. Studies have shown that increasing the stress hormone levels, cortisol, in patients weakens the immune system and exacerbates anxiety and stress, and jeopardizes the recovery process, all of which reduces the QoL [36, 37]; While, exercise lowers cortisol.

**Conclusions**

In general, according to the studies, exercising regularly improves indicators such as stress, self-esteem, and QoL, and probably cope better with COVID-19. Low PAL may be a possible cause of COVID-19 among the subjects in the present study. Also, the low GH and QoL of CRI in the present study might be due to the increased stress and anxiety caused by COVID-19. Maintaining adequate PAL during the COVID-19 outbreak can play a preventive role. Also, the spread of the COVID-19 and the hypochondriasis have now led to higher levels of inactivity, stress, and anxiety in the community, which has reduced the MH and QoL attenuating the immune system. Therefore, exercising regularly and maintaining adequate PAL, following hygiene protocols, are among the efficient and effective approaches to increase the QoL and GH in CRI.

**Abbreviations**

PAL: physical activity level; QoL: quality of life; GH: general health; CRI: COVID-19 recovered individuals; IPAQ-SF: International Physical Activity Questionnaire; PCS: physical component summary; MCS: mental component summary.
Declarations

Acknowledgments

The authors would like to thank the subjects for their willing participation in this study.

Authors’ contributions

RH designed the study. MA experimented. RH analyzed the data and wrote the manuscript. EA involved in the interpretation of data, reviewed and edited the manuscript. All authors read and approved the final manuscript.

Funding

The author(s) received no specific funding for this work.

Availability of data and materials

The datasets used and/or analyzed during the current study are available from the corresponding author on reasonable request.

Ethics approval and consent to participate.

This study was approved by the ethics committee of Razi University of Kermanshah (IR.RAZI.REC.1399.064).
