A CLASS OF FINITE SIMPLE BOL LOOPS OF EXPONENT 2

GÁBOR P. NAGY

Abstract. In this paper we give an infinite class of finite simple right Bol loops of exponent 2. The right multiplication group of these loops is an extension of an elementary Abelian 2-group by $S_5$. The construction uses the description of the structure of such loops given by M. Aschbacher. These results answer some questions of M. Aschbacher.

1. Introduction

The set $Q$ endowed with a binary operation $x \cdot y = xy$ is a loop if it has a unit element 1 and the equation $xy = z$ has a unique solution whenever two of the three unknowns are given. The loop $Q$ is a (right) Bol loop if the identity

$$(xy)z = x(y(zy))$$

holds for all $x, y, z \in Q$. Bol loops of exponent 2 play an important role in the theory of loops and are related to interesting group theoretical problems. Using the so called Baer correspondence, this class of loops can be described by a triple $(G, H, K)$ with group $G$, core-free subgroup $H \leq G$ and system of coset representatives $K \subseteq G$ such that $1 \in K$, $G = \langle K \rangle$ and $K \setminus \{1\}$ is a union of conjugacy classes of involutions.

Bol loops of exponent 2 which are not elementary Abelian groups have long been known to exist, the first construction is due to R. P. Burn. Later, many infinite classes of such loops were given, see [11, 12, 13, 16]. All of these examples were solvable loops; equivalently the group $G$ was a 2-group. The existence of nonsolvable finite Bol loops of exponent 2 was considered as one of the main open problem in the theory of loops and quasigroups. As the smallest such loop must be simple, this question was related to the existence of finite simple proper right Bol loops. Here by proper we mean right Bol loops which are not Moufang, that is, which do not satisfy the identity $x(yx) = (xy)x$. Finite simple proper Bol loops were constructed by the author [17] recently.

By [15], the solvability of a Bol loop of 2-power exponent is equivalent to having 2-power order. Later, S. Heiss [9] showed that the solvability of the loop corresponding to the triple $(G, H, K)$ is equivalent with the solvability of the group $G$. The next major step was the paper [3] by M. Aschbacher. His main result gives a detailed description on the structure of the right multiplication group of minimal nonsolvable Bol loops of exponent 2. This result was achieved by using the classification of finite simple groups.

2000 Mathematics Subject Classification. Primary 20N05; Secondary 20C20, 20F29.

This paper was written during the author’s Marie Curie Fellowship MEIF-CT-2006-041105.
In this paper we apply Aschbacher’s recipe to construct a class of finite simple Bol loops of exponent 2. In this way, we give a negative answer to questions 2 and 3 of [3] and [4]. The smallest member of our class has order 96. We emphasize that this example is small and the structural description of the smallest example in [3] and [4] is so precise that it was only a matter of time that somebody finds it by some short computer calculation. This explains the fact that this loop was independently discovered by the author and by B. Baumeister and A. Stein [5] with a time delay of 10 days.

Acknowledgement I would like to thank Michael Aschbacher (California Institute of Technology) for his detailed comments on the previous version of this paper. He helped to fill some gaps, to simplify the proofs and to replace computer based calculations by theoretical arguments. I also would like to thank Peter Müller (Würzburg) for many stimulating conversations and helpful comments.

2. Basic concepts

In order to make this paper self-contained, we define the basic loop theoretical concepts. Subloops, homomorphisms and normal subloops can be defined for the class of loops similarly to groups, see [6]. The loop $Q$ is said to be simple if it has no proper normal subloops.

For a loop $Q$, the maps $L_a, R_a : Q \to Q$, $L_a(x) = ax, R_a(x) = xa$ are the left and right multiplication maps of $Q$. They are bijections of $Q$ and generate the left and right multiplication groups of $Q$, respectively. The section $S(Q)$ of the loop $Q$ is the set of the right multiplication maps of $Q$.

The right Bol identity can equivalently be expressed by $R_xR_yR_x \in S(Q)$ for all $x, y \in Q$. Bol loops are power-associative, that is, $x^n$ is well defined for all $x \in Q$ and $n \in \mathbb{Z}$. The order of the element $x$ is the smallest positive integer $n$ such that $x^n = 1$. The exponent of $Q$ is the smallest positive integer $n$ such that $x^n = 1$ for each $x \in Q$.

We will formulate our results by using the Baer correspondence between the class of loops and the class of triples $(G, H, K)$ where $G$ is a group, $H \leq G$ and $K$ is a set of coset representatives of all conjugates $H^g$ in $G$, and $1 \in K$. For a given loop $Q$, $G$ can be chosen to be the right multiplication group, $H$ the stabilizer of the unit element and $K$ the set of right multiplication maps. Conversely, for a given triple $(G, H, K)$, a loop can be constructed in the following way. We define the operation $x \circ y$ on $K$ by $H(x \circ y) = Hxy$; then $Q = (K, \circ)$ is a loop. The triple satisfying the above condition will be said to be a loop folder.

The loop folder $(G, H, K)$ determines a Bol loop of exponent 2 if and only if $K = \{1\} \cup \bigcup_{i \in I} C_i$, where the $C_i$’s are conjugacy classes of involutions in $G$.

3. The first construction

As usual, $S_5$ and $PGL(2, 5)$ are the permutation groups acting on 5 and 6 points, respectively. It is well known that $S_5 \cong PGL(2, 5) \cong \text{Aut}(L_2(4)) \cong O^-_4(2)$, where $\text{Aut}(L_2(4))$ is the extension of $L_2(4) = PSL(2, 4) \cong A_5$ by a field automorphism of order 2, and $O^-_4(2)$ is the orthogonal group on a
Lemma 3.3. The group $u$ moves $u$. Moreover, with $d = (1, 2, 3, 4)$ acting on $F_2$ of Witt index 1. We denote by $F_2$ the affine linear group acting on $F_5$. On the one hand, $F_2$ is the Borel subgroup of $PGL(2, 5)$, that is, the stabilizer of a projective point. On the other hand, $F_2 \leq S_5$ is a sharply 2-transitive permutation group on 5 points.

In the sequel, we define a group $G$ which is a nonsplit extension of the elementary Abelian group of order 32 by $S_5$ such that the transpositions of $S_5$ lift to involutions in $G$ and the even involutions of $S_5$ lift to elements of order 4. Despite the relatively small order of $G$, we found no simple description for this group; therefore our definition will be rather ad hoc, as well. We start with two technical lemmas.

Lemma 3.1. We have the following presentations of groups with generators and relations.

\[ A_5 = \langle a, b \mid a^2 = b^3 = (ab)^5 = 1 \rangle, \]
\[ S_5 = \langle c, d \mid c^2 = d^4 = (cd)^5 = [c, d]^3 = 1 \rangle, \]
\[ 2S_5 = \langle C, D \mid C^2 = D^8 = (CD)^5 = [C, D]^3 = [C, D^4] = 1 \rangle, \]

where $2S_5$ denotes the nonsplit central extension of $S_5$ in which the transpositions lift to involutions. In other words, $2S_5$ is the semidirect product of $SL(2, 5) = 2.A_5$ with a group of order 2.

Proof. The presentation for $A_5$ is well known. Assume $G = \langle c, d \rangle$ is the group presented by the second set of relations above. We observe first that $S_5$ satisfies these relations, hence no relation can collapse. Put $a = d^2$ and $b = [d, c] = [c, d]^{-1}$. Then $a^2 = b^3 = 1$ and $ab = (dc)^2 = ((cd)^2)^c$. This latter implies $(ab)^5 = 1$, hence $G_0 = \langle a, b \rangle \cong A_5$. Moreover, since $dc = (dc)^6 = (ab)^3 \in G_0$, we have $cd = dc[c, d] = dcb^{-1} \in G_0$ and

\[ dbd^{-1} = cdc^{-1} = (cd)^2d^{-2} \in G_0. \]

This means that $d$ and $cd$ normalize $G_0$, so $G_0 \triangleleft G$. So $|G : G_0| = 2$ and $d \notin G_0$ since $A_5$ contains no element of order 4. This proves $G \cong S_5$. Finally, $D^4$ is a central involution in $H = \langle C, D \rangle$ and $H/\langle D^4 \rangle$ maps surjectively to $S_5$. The order of $D$ is 8, thus, the extension is nonsplit and the involution $C$ covers a transposition in $S_5$. \qed

Lemma 3.2. The permutations

\[
\begin{align*}
c & = (1, 4)(2, 9)(3, 10)(6, 11)(7, 12)(13, 21)(14, 22)(15, 24)(16, 23)(17, 30) \\
& \quad (18, 29)(19, 31)(20, 32)(33, 35)(38, 40), \\
d & = (1, 2, 4, 6, 8, 7, 5, 3)(9, 13, 25, 18, 10, 14, 26, 17)(11, 15, 27, 20, 12, 16, 28, 19)(21, 30, 38, 34, 23, 31, 40, 35)(22, 32, 39, 36, 24, 29, 37, 33)
\end{align*}
\]

acting on 40 points satisfy the relations

\[ c^2 = d^8 = (cd)^5 = [c, d]^3 = [d^4, c]^2 = [d^4, cdcd^{-2} c] = 1. \]

Moreover, with $u_1 = d^4$, $u_2 = u_1^{-1}$, $u_3 = u_1^{-d}$, $u_4 = u_1^{cd}$, $u_5 = u_1^{cdec}$, $u_6 = u_1^{cded}$. The identity $u_1 u_2 u_3 u_4 u_5 u_6 = 1$ holds.

Proof. We leave the straightforward calculations to the reader. \qed

Lemma 3.3. The group $G = \langle c, d \rangle$ given in Lemma 3.2 satisfies
satisfy the relations of $S$ shows by straightforward calculation that $\tilde{c}$ is unique, we have a conjugacy class in $G$ of perfect groups in the computer algebra system GAP \cite{8} and constructed consists of the elements $u_i | \text{Abelian 2-group and Lemma 3.4.}

The action of $d$ on $X$ is therefore $(u_2u_3u_4u_5)$. This not only shows that $X$ is a conjugacy class in $G$, but we also have the action of $G$ on $X$. Indeed, one shows by straightforward calculation that $\tilde{c} = (12)(34)(56)$ and $\tilde{d} = (2345)$ satisfy the relations of $S_5$ from Lemma 3.1. Since the action of $S_5$ on 6 points is unique, we have $G/C_G(X) \cong \text{PGL}(2,5)$.

As $[u_1, u_2] = [d^4, cd^4c] = [d^4, c]^2 = 1$ and $\text{PGL}(2,5)$ acts 2-transitively, $[u_i, u_j] = 1$ holds for all $i, j$. This means that $J = \langle X \rangle$ is an elementary Abelian 2-group and $|J| = 32$ by $u_1 \cdots u_6 = 1$. Using the presentation of $2.S_5$ from Lemma 3.1 $G/J_0 \cong 2.S_5$. This implies

$$[G,G]/[G,J] \cong [G/J_0, G/J_0] \cong 2.A_5 \cong \text{SL}(2,5).$$

Finally, $G$ splits over $[G,G]J$ as $c \not\in [G,G]J$. \hfill $\square$

In the sequel, $G$ will denote a group satisfying (*). We would like to make clear that it can be shown using the computer algebra system GAP \cite{8} that the group given in Lemma 3.2 is the unique group with this property. However, we hope that this more general approach will help in future generalization of the constructions of this paper.

Among other properties, we show in the next lemma that for our group $G, G' = [G,G]$ is a perfect group. Actually, we found $G'$ by using the library of perfect groups in the computer algebra system GAP \cite{8} and constructed $G$ as a split extension of $G'$ by an outer automorphism of order 2.

**Lemma 3.4.** Let $G$ be a group satisfying (*) and define $J_0 = [G,J]$.

(i) We have $G'' = G' = [G,G] = [G,G]J$ and $|G : G'| = 2$. In particular, all involutions of $G' = [G,G] = [G,G]J$ lie in $J$.

(ii) Let $P$ be a Sylow 5-subgroup. Then $N_{J_0}(P) = \{1\}$ and $N_G(P) \cong C_5 \times C_5$. Moreover, if the subgroup $U \leq G$ maps onto $F_20$ modulo $J$ then $U = N_G(P)$ or $U = N_G(J_0)$.

Proof. (i) Let $V$ be the permutation $F_2$-module of $\text{PGL}(2,5)$ with basis $\{u_1, \ldots, u_6\}$. Due to the 2-transitivity, the orbit of the element $u_i + u_j, i \neq j$ which are different modulo the center $\langle u_1 + \ldots + u_6 \rangle$ of $V$. Hence both $\text{PGL}(2,5)$ and $\text{PSL}(2,5)$ act transitively on
the nonidentity elements of $J_0 = [G, J]$, which implies that $J_0$ is a minimal normal subgroup in $G$ and $[G, G]J$. It follows that $J_0 = [G', J_0]$ and $G'/J_0 = (G'/J_0)' = G'/J_0$ by $SL(2, 5) = SL(2, 5)$. This means $G'' = G'$. Finally, $J \leq G'$ follows from $J/J_0 = Z(G/J_0) \leq (G/J_0)' = G'/J_0$.

(ii) Since $G$ splits over $G' = G'J$ we can take an involution $c$ from $G \backslash G'$; the image of $c$ in $G/J \cong S_5$ is a transposition. As $J$ is the permutation module modulo its center, $\dim_{F} C_{J_0}(c) = 2$ and $\dim_{F}(C_{J}(c)) = 3$. It is easy to check that $2S_5 \cong G/J_0$ contains 20 non-central involutions and they are all conjugate.

Let $c'$ be another involution in $G\backslash J$; we want show that $c, c'$ are conjugate. For some $g \in G$, $(cJ_0)^{gJ_0} = c'J_0$, that is, $c^{g} \in c'J_0$. Hence we can assume $c \in c'J_0$, $c = cj$ with $j \in J_0$. The element $cj$ has order 2 if and only if $j \in C_{J_0}(c)$. On the one hand, $c^{gJ_0} \leq cC_{J_0}(c)$. On the other hand, $c^{gJ_0} = cC_{J_0}(c)$ and $c' \in c^{gJ_0}$. No involution of $G'$ can be conjugate to $c$, hence all involutions of $G'$ must lie in $J$. Finally, we show $|c^{gJ_0}| = 80$. As $c^{g} \in cJ_0$ if and only if $c^{g} = cj$ for some $j \in J_0$, we have $N_{G}(cJ_0) = C_{G}(cJ_0)$. Moreover, $C_{G/J_0}(cJ_0) = N_{G}(cJ_0)/J_0$. Thus,

$$|G : C_{G}(c)| = |G : N_{G}(cJ_0)||C_{G}(c)| = |G/J_0 : C_{G/J_0}(cJ_0)||J_0 : C_{J_0}(c)| = |cJ_0|G/J_0 |cJ_0| = |cJ_0|G/J_0|cJ_0| = 20\cdot 4 = 80.$$

(iii) $P$ acts fixed point free on the involutions of $J_0$, thus, $N_{J_0}(P) = 1$. Moreover, $5 \nmid |J| - 1$, hence $P$ centralizes a unique element $a \in J$. Let $U$ be a preimage of $F_{20}$ modulo $J$ and put $\bar{U} = U/\langle a \rangle$, $\bar{J} = J/\langle a \rangle$. Then $\bar{J}$ is a minimal normal subgroup of $\bar{U}$. Since $F_{20} = U/\bar{J}$ acts faithfully on $\bar{J}$, we have $C_{\bar{U}}(\bar{J}) = \bar{J}$. By [10], II.3.3 satz, $\bar{J}$ has a complement $H$ in $\bar{U}$, $H \cong F_{20}$. Let $H$ be the preimage of $H$, then $H$ has a unique (hence normal) 5-Sylow and $H \cong C_{8} \times C_{5}$. This shows $N_{G}(P) \cong C_{8} \times C_{5}$. For the last statement, record that $U \cap J_0$ is either 1 or $J_0$.

The following proposition will apply in all of our examples of Bol loop folders of exponent 2. We hope that it will also apply in future constructions not considered here. Recall that $O_{2}(G)$ is the largest normal 2-subgroup of $G$.

**Proposition 3.5.** Assume $G$ is a finite group, $J = O_{2}(G)$ and $G^{+} = G/J \cong S_{5}$. We denote by $g^{+}$ the element of $S_{5}$ corresponding to $gJ$. Set $L = G^{+}J$, $K_{1}$ the involutions in $G \backslash L$, $K_{0}$ a $G$-invariant subset of $J$ containing 1 such that $K_{0} \setminus \{1\}$ consists of involutions, and $H \leq G$. Set $K = K_{0} \cup K_{1}$, $n_{0} = |K_{0}|$, and $n_{1} = |K_{1} \cap aJ|$ for $a \in K_{1}$. Assume

(a) $(J, H \cap J, K_{0})$ is a Bol loop folder of exponent 2.
(b) $n_{0} = 2n_{1}$.
(c) $|G^{+} : H^{+}| = 6$.
(d) For each $a \in K_{1}$, $C_{H \cap J}(a) = 1$.
(e) Every involution of $L$ is contained in $J$.

Then $(G, H, K)$ is a Bol loop folder of exponent 2, and $|K| = 6n_{0} = 12n_{1}$.
Proof. First $K_1^+$ is the set of transpositions of $S_5$, so $|K_1^+| = 10$. This implies that $n_1$ is well defined. Indeed, for $a, b \in K_1$, $aJ, bJ$ are conjugate, hence $K_1 \cap aJ, K_1 \cap bJ$ are conjugate in $G$. Moreover, $|K_1| = 10n_1$ and by (b),

$$|K| = |K_0| + |K_1| = 2n_1 + 10n_1 = 12n_1 = 6n_0.$$ 

Next by (a) and (c),

$$|G : H| = |G : HJ||HJ : H| = |G^+ : H^+||J : J \cap H| = 6|K_0| = 6n_0,$$

so $|G : H| = |K|$.

We claim $xy \notin H$ for distinct $x, y \in K$. If so, as $|G : H| = |K|$, $K$ is a set of coset representatives for $H$ in $G$. Then as $K$ is $G$-invariant and $K \setminus \{1\}$ consists of involutions, $(G, H, K)$ is a Bol loop folder of exponent 2.

If $x, y \in J$ then $x, y \in K_0$, so $xy \notin H$ by (a). Next $K_1^+ \cap H^+ = \emptyset$, so if $x \in J$ and $y \in K_1$ then $(xy)^+ = y^+ \notin H^+$, so $xy \notin H$. Thus we may take $x, y \in K_1$ and $xy \in H$. Now as $K_1^+$ is a set of transpositions in $S_5$, the order of $(xy)^+$ is 1, 2 or 3. Since $H^+ \cong F_{20}$ has no element of order 3, we get $(xy)^2 \in J$. In particular, $D = \langle x, y \rangle$ is a 2-group. Let $z$ be the unique involution in $(xy)$. By $xy \in L$ and (e), $z \in H \cap J$. Moreover, $x, y$ commute with $z$, which contradicts to (d). \qed

Remark The fact that (e) is necessary can be seen from the counterexample $G = S_5 \rtimes J$.

Theorem 3.6. Assume $G$ is a group satisfying condition (*) of Lemma 3.3. Let $J_0$ be the minimal normal subgroup of $G$ and put $K = J_0 \cup cG$. Define $H = \text{NG}(P)$ where $P$ is a 5-Sylow subgroup of $G$. Then $(G, H, K)$ is a Bol loop folder determining a simple Bol loop of exponent 2 of order 96. Conversely, if $(G, H^*, K^*)$ is an exponent 2 Bol loop folder then $H^*$ is a conjugate of $H$ and $K^* = K$.

Proof. With the notation of Proposition 3.3 $K_0 = J_0$ and $K_1 = cG$. Then $n_0 = 16$, $n_1 = |cG \cap cJ| = 80/10 = 8$ and $|G^+ : H^+| = 6$, so (b) and (c) hold. (e) follows from Lemma 3.3(ii). Since $J$ is elementary Abelian, $H \cap J$ consists of 1 and the unique involution of $H$. This involution cannot be centralized by $c$, otherwise it would be central in $G = \langle c, P, J \rangle$; hence (d). Finally, $H \cap J$ is not contained in $J_0$, therefore $J_0$ is a complement to $H \cap J$ in $J$; showing (a). By Proposition 3.3 $(G, H, K)$ is a Bol loop folder of exponent 2.

For the converse, we observe that $(G, H^*, K^*)$ determines a Bol loop of exponent 2 with all proper subloops solvable. Thus, by the Main Theorem of 3, $H^*$ maps surjectively to $F_{20}$. By Lemma 3.4(iii), $H^* = H$ or $H^* = HJ_0$ up to conjugation. In the latter case, the loop has order 6 which is impossible. Again by Aschbacher’s result, $cG \subset K^*$. Finally, if $J_0 \subsetneq K^*$, then $K^*$ will contain a conjugate of the involution of $H$, which is not possible. This proves the theorem. \qed

As the group given in Lemma 3.2 satisfies (*), we have:

Corollary 3.7. There exists a simple Bol loop of exponent 2 and order 96. \qed
Remark The Bol loop folder \((G, H, K)\) of Theorem 3.6 was discovered independently by B. Baumeister and A. Stein [5] (Free University of Berlin), as well.

4. \(S_5\)-modules over \(\mathbb{F}_2\)

In this section we collect some useful facts about \(kS_5\)-modules, where \(k\) is a field of characteristic 2.

**Lemma 4.1.** The group \(S_5\) has three absolutely irreducible representations over \(\mathbb{F}_2\): the trivial representation and two representations \(M, N\) of dimension 4. The two 4-dimensional modules can be distinguished by the fact that \(C_M(x) = 0\) and \(\dim_{\mathbb{F}_2}(C_N(x)) = 2\) for an element \(x \in S_5\) of order 3. Moreover, the following hold.

(i) \(M\) is the 4-dimensional irreducible component in the 6-dimensional permutation module for \(S_5 \cong \text{PGL}(2, 5)\). Also, let \(V\) be the natural 2-dimensional module of \(A_5 \cong \text{SL}(2, 4)\) over the field \(\mathbb{F}_4\) and \(\sigma\) be semilinear map of \(V\) induced by the Frobenius automorphism of \(\mathbb{F}_4\). Then \(S_5 \cong \text{SL}(2, 4) \rtimes \langle \sigma \rangle\) and \(V\) is a 4-dimensional \(S_5\)-module over \(\mathbb{F}_2\). The \(S_5\)-modules \(M\) and \(V\) are isomorphic.

(ii) \(N\) is the 4-dimensional irreducible component in the 5-dimensional permutation module of \(S_5\). Also if \(N\) is a 4-dimensional orthogonal space of Witt index 1 over \(\mathbb{F}_2\), then \(O(N) = O_4^{-}(2) \cong S_5\). Note that \(N\) has 5 singular and 10 nonsingular vectors and these are the \(S_5\)-orbits on \(N\).

(iii) \(N\) is absolutely irreducible as \(A_5\)-module. \(M\) is irreducible but not absolutely irreducible as \(A_5\)-module, the splitting field being \(\mathbb{F}_4\). In particular, the modules are nonisomorphic as \(A_5\)-modules.

(iv) \(N\) and \(M\) are isomorphic absolutely irreducible projective \(F_{20}\)-modules.

**Proof.** Let us first define \(N, M\) as irreducible components of the permutation modules. By [14] Table 1, they are absolutely irreducible. As \(S_5\) has 3 classes of elements of odd order, by [1] Theorem 3.2 \(S_5\) has no other absolutely irreducible modules over \(\mathbb{F}_2\). The properties of \(N, M\) can be verified by straightforward calculations, the irreducibility as \(A_5\) and \(F_{20}\)-modules follows again from [14, Table 1]. We show \(N_{F_{20}} \cong M_{F_{20}}\). As \(F_{20}\) has two classes of elements of odd order, \(F_{20}\) has two absolutely irreducible modules: the trivial one and \(N_{F_{20}}\) coming from the 2-transitive permutation representation. So if \(M_{F_{20}}\) were not isomorphic to \(N_{F_{20}}\) then it could be brought to upper triangular form over \(\mathbb{F}_2\), which is clearly impossible.

It remains to show that \(N_{F_{20}}\) is projective. Since \(N_{C_4}\) is isomorphic to the group algebra \(\mathbb{F}_2C_4\), it is a projective \(C_4\)-module by [1] Theorem 4.2. Using [1, Corollary 9.3], we obtain that \(N\) is projective as \(F_{20}\)-module. \(\square\)

We observe that these \(S_5\)-modules can immediately be constructed using the Steinberg Tensor Product Theorem [18, Theorem 13.1], as well.

We will now construct an \(S_5\)-module \(U\) which will play a central role in the generalization of our first construction of a Bol loop of exponent 2.

Let \(U = U_1 \oplus U_2\) be the direct sum of two copies of \(N\) as an \(\mathbb{F}_2A_5\)-module. As \(U_i\) is an orthogonal space, we can regard \(U\) as an orthogonal space which
is the orthogonal direct sum of the two nondegenerate subspaces $U_1$ and $U_2$. The stabilizer $B$ of \{${U_1, U_2}$\} in $O(U)$ is $(G_1 \times G_2)(\tau)$ where
\[
G_i = C_{O(U)}(U_{3-i}) \cong O(U_i) \cong S_5
\]
and $\tau$ is an involution interchanging $U_1, U_2$. Thus $B$ is the wreath product of $S_5$ with $C_2$. In particular, the elements $\tau$ and $(g_1, g_2) \in G_1G_2$ map $u_1 \oplus u_2 \in U$ to
\[
(u_1 \oplus u_2)\tau = u_2 \oplus u_1, \text{ and } (u_1 \oplus u_2)(g_1, g_2) = u_1g_1 \oplus u_2g_2,
\]
respectively. Set
\[
G_0 = C_{G_1G_2}(\tau) = \{ (g, g) \mid g \in S_2 \} \cong S_5,
\]
and let $L = [G_0, G_0] \cong A_5$, $t_0$ an involution (transposition) in $G_0 \setminus L$, $t = t_0\tau$, and $D = L\langle t \rangle$. Then $t\tau = \tau t$ and the action of $t$ on $U$ is
\[
(u_1 \oplus u_2)t = u_2c \oplus u_1c,
\]
where $c \in S_5$ is the transposition corresponding to $t_0$. It is immediate that $D \cong S_5$.

Set $W = C_U(\tau)$. Then $W$ is an $F_2D$-submodule of $U$, and also
\[
W = [U, \tau] = \{ u + ur \mid u \in U_1 \} = \{ u \oplus u \mid u \in N \},
\]
with the map $u \mapsto [u, \tau] = u + ur$ an $F_2L$-isomorphism of $U_1$ with $W$. If $Q$ is the quadratic form on $U$ then as $Q(u_1 \oplus u_2) = Q(u_1) + Q(u_2)$ and $Q(u) = Q(u\tau)$, $[u, \tau]$ is singular, so $W$ is totally singular.

**Lemma 4.2.** With the notation above, we have:

(i) $U$ has 3 irreducible $L$-submodules, namely $U_1, U_2$ and $W$.
(ii) $W$ is the unique proper $D$-submodule of $U$.
(iii) Let $P$ be a Sylow 5-subgroup of $D$, $D_1 = N_D(P)$. Then $D_1 \cong F_{20}$ and $U$ has precisely 3 $D_1$-submodules $W, T_1, T_2$.
(iv) The orbits of $D_1$ on $T_1$ have length 1, 5, 10. In particular, each member of $T_1$ is fixed by some involution of $D_1$.

**Proof.** By Lemma 4.1, $N$ is projective as $F_{20}$-module. Since $U/W$ is a 4-dimensional irreducible for $D_1, U_{D_1}$ splits over $W_{D_1} \cong N_{D_1}$ and hence $U = W \oplus T_1$ with $D_1$-submodule $T_1$. Again by Lemma 4.1, $N_L$ and $N_{D_1}$ are completely irreducible, Schur’s lemma then implies $\text{End}_{F_2L}(N) = \text{End}_{F_2D_1}(N) = F_2$. We can now apply [2] (27.14) to obtain (i) and (iii). (ii) follows from (i). Finally, (iv) holds since $T_1$ and $W$ are $D_1$-isomorphic and $W$ is the permutation module modulo the center. \(\square\)

In the next lemma, we keep using the above notation.

**Lemma 4.3.** (i) $\dim C_U(t) = 4$, $C_U(t) + T_1 = U$ and $C_U(t) \cap T_1 = 0$.
(ii) Under the action of $A_5$ on the submodules $W, U_1, U_2$ of $U$, the lengths of the orbits are 1, 5, 10. Let $S_0, S_1, S_2$ be the orbits of length 5 in $W, U_1, U_2$, respectively. Then $S = \{0\} \cup S_0 \cup S_1 \cup S_2$ is a (nonlinear) $S_5$-invariant complement to $T_1$ in $U$, that is, $S + T_1 = U$. 

Proof. (i) We have $D = L(t) \cong S_5$. Let us denote the element of $S_5$ corresponding to $a \in D$ by $a^+$. w.l.o.g. we can assume $t^+ = (12)$ and $P^+ = \langle (12345) \rangle$. Then $D_1^+ = \langle (12345), (1325) \rangle$. Let $b \in D$ such that $b^+ = (12)(35)$. Then $b \in D_1$ and $b$ commutes with $t$ and $\tau$. Record that the action of $b, t, \tau$ on $U$ is

$$
b : u_1 \oplus u_2 \mapsto u_1 b^+ \oplus u_2 b^+, \quad \tau : u_1 \oplus u_2 \mapsto u_2 \oplus u_1, \quad t : u_1 \oplus u_2 \mapsto u_2 t^+ \oplus u_1 t^+.
$$

Define the element $\tilde{c} \in B$ by

$$\tilde{c} : u_1 \oplus u_2 \mapsto u_1 t^+ \oplus u_2.$$

Then $\tilde{c}$ commutes with $b$ and $\tau \tilde{c} = t$. Put $E_1 = \langle t, b \rangle$, clearly $E_1^\tilde{c} = \langle \tau, b \rangle$. On the one hand, we have

$$\dim_{\mathbb{F}_2}(C_U(E_1)) = \dim(C_U(\tau, b)) = \dim C_{U_1}(b) = \dim C_{U_1}(b) \oplus C_{U_2}(b)(\tau) = \dim C_{U_1}(b) = \dim C_N(b^+) = 2.
$$

We show on the other hand that $\dim_{\mathbb{F}_2}(C_W(E_1)) \geq 2$. Indeed, the $S_5$-modules $W$ and $N$ are isomorphic and $\dim(C_W(t)) = \dim(C_N(t^+)) = 3$. Then $C_W(E_1) = C_{U_1}(b)$ is of rank at least $\dim(C_W(t))/2 = 3/2$.

Now, from $\dim(C_W(E_1)) \geq 2$ follows $C_U(E_1) \leq W$. However if $C_{T_1}(t) \neq 0$ then $C_{T_1}(E_1) \neq 0$, contradicting $T_1 \cap W = 0$ and $C_U(E_1) \leq W$.

(ii) We have seen that $S_i$ is the set of singular points in $U_i$ for $i = 1, 2$. The action of $D_1 \cong F_{20}$ on $S_i$ is its natural 2-transitive action on 5 points. $D_1 \cap L$ contains precisely 5 involutions and each member of $S_i$ is fixed by exactly one involution of $D_1 \cap L$. Moreover, each member of $T_1$ is fixed by some involution of $D_1$.

We have to show that for distinct $x, y \in S$, $x + y \notin T_1$; then $S$ is a complement to $T_1$ by an order argument. Assume $x + y \in T_1$ and denote by $a$ an involution of $D_1$ fixing $x + y$. Then $x, y$ are the projections of $x + y$ on $S_i, S_j$, so $a$ fixes the projections $x$ and $y$. As $T_1 \cap U_i = 0$ for $0 \leq i \leq 2$, $x \in S_i$ and $y \in S_j$ for some $i \neq j$. If $x \in S_1$ and $y \in S_2$, then $x$ and $y$ are the unique fixed points of $a$ in $S_1, S_2$. By $a \tau = \tau a, x \tau = y$ holds, and hence $x + y = [x, \tau] \in W$, contradicting $T_1 \cap W = 0$.

Thus we may take $x \in S_0$ and $y \in S_1$. Then $x = x_1 + x_2$ with $x_i = S_i$, and as $x \in S_0, x_2 = x_1 \tau$ with $x_i \in S_i$. Now, $x_1$ is the unique fixed point of $a$ in $S_i$ and $y$ the unique fixed point of $a$ in $S_1$, so $y = x_1$ and $x + y = x_1 + x_2 + y = x_2 \in T_1 \cap U_2 = 0$, a contradiction.

5. An infinite family of simple Bol loops of exponent 2

In this section, $G$ denotes a group satisfying condition (*) of Lemma 3.3. $H$ is the normalizer of a 5-Sylow $P$ of $G$, $c$ an involution from $G \setminus [G, G]J$. The $S_5$-modules $N$ and $U$ are defined as in Section 4. Also $U = U_1 \oplus U_2 = T_1 \oplus T_2$ where $U_1, U_2$ are $A_5$-submodules, and $T_1, T_2$ are $F_{20}$-submodules. Moreover,
Let us fix a positive integer $k$ and put
\[ \mathcal{U} = U^k, \quad \mathcal{U}_i = U_i^k, \quad \mathcal{F}_i = T_i^k, \quad \mathcal{W} = W^k. \]

Clearly, $\mathcal{W}$ is a $S_5$-submodule and $\mathcal{U} = \mathcal{U}_1 \oplus \mathcal{U}_2 = \mathcal{F}_1 \oplus \mathcal{F}_2$. We write $\mathcal{G} = G \ltimes \mathcal{U}$ where $J \triangleleft G$ acts trivially on the $S_5$-module $\mathcal{U}$. Moreover, $\mathcal{F} = O_2(\mathcal{G}) = (J, \mathcal{W})$.

We will consider the elementary Abelian subgroup $\mathcal{F}$ of $\mathcal{G}$ as an $S_5$-module over the field $\mathbb{F}_2$. In particular, with some abuse of notation, we will denote the group operation on $\mathcal{F}$ additively and write $\mathcal{F} = J + \mathcal{W}$, etc. It is easy to see that
\[ \mathcal{G} / \mathcal{F} \cong S_5 \text{ and } \text{soc}(\mathcal{G}) = J_0 + \mathcal{W}. \]

Moreover, since $J_0$ and $W$ are non-isomorphic $S_5$-modules, $J_0 \oplus W$ does not contain diagonal submodules. This implies that for any minimal submodule $M$ of $\mathcal{F}$, we either have $M = J_0$ or $M \leq \mathcal{W}$.

The action of the involution $c \in G \setminus J$ on $\mathcal{U}$ equals the action of the transposition $(12) \in S_5$, hence $c$ interchanges $\mathcal{U}_1, \mathcal{U}_2$. This implies $|C_{\mathcal{U}}(c)| = 16^k$ and $|c^{\mathcal{U}}| = 16^k$; that is, $\mathcal{U}$ is transitive on the involutions in $c^\mathcal{U}$. As $G \cong \mathcal{G} / \mathcal{U}$ is transitive on the 80 involutions in $G \setminus J$, and as $\mathcal{U}$ is transitive on the $16^k$ involutions on $c^\mathcal{U}$, $\mathcal{G}$ is transitive on the 80 involutions in $\mathcal{G} \setminus \mathcal{F}$.

Using Aschbacher’s Main Theorem [3] we conclude that a Bol loop folder $(\mathcal{G}, \mathcal{H}, \mathcal{X})$ must have the following properties: The index of $\mathcal{H}$ has to be $96 \cdot 16^k$, that is, $\mathcal{H}$ must have order $40 \cdot 16^k$. The set of involutions $\mathcal{X}$ is the union of $c^\mathcal{G}$ and $\mathcal{H} \cap \mathcal{F}$, thus, $|\mathcal{X} \cap \mathcal{F}| = 16 \cdot 16^k$.

There are very many possible choices for $\mathcal{H}$ and $\mathcal{X}$. The most obvious choice is the following.

**Proposition 5.1.** Put $\mathcal{H} = H \ltimes \mathcal{T}_1$ and $\mathcal{X} = c^\mathcal{G} \cup (J_0 \oplus \mathcal{W})$. Then $(\mathcal{G}, \mathcal{H}, \mathcal{X})$ is a Bol loop folder. Moreover, the homomorphism $\mathcal{G} \rightarrow G$ with kernel $\mathcal{U}$ induces a surjective homomorphism between the loop folders $(\mathcal{G}, \mathcal{H}, \mathcal{X})$ and $(G, H, K)$. In other words, the Bol loop corresponding to $(\mathcal{G}, \mathcal{H}, \mathcal{X})$ is an extension of the elementary Abelian group of order $2^{2k}$ by the loop corresponding to $(G, H, K)$.

**Proof.** We apply Proposition 3.5: (a), (c) and (e) are trivial. (b) follows from
\[ n_1 = |c^\mathcal{G} \cap c \mathcal{F}| = |C_{\mathcal{F}}(c)| = 8|C_{\mathcal{U}}(c)| = 8 \cdot 16^k \]
and $n_0 = |J_0||\mathcal{W}| = 16 \cdot 16^k = 2n_1$. For (d), we use
\[ C_{\mathcal{H} \cap \mathcal{F}}(c) = C_{H \cap J \cup \mathcal{T}_1}(c) = C_{H \cap J}(c) = 1, \]
as by Lemma 4.3 $\mathcal{T}_1 \cap \mathcal{T}_1^c = 0$. \hfill \Box

In the rest of this section, for each integer $k \geq 1$, we modify these $\mathcal{H}$ and $\mathcal{X}$ such that the resulting loop will be simple. Let $U^*$ be a copy of $U$ in $\mathcal{U}$ such that $\mathcal{U} = U^* \oplus U^{k-1}$. We denote the subspaces corresponding to $T_i, U_i, W$ by $T_i^*, U_i^*, W^*$. Let us define the set $S \subseteq U$ as in Lemma 4.3(ii)
and let $S^*$ be the corresponding subset of $U^*$. In order to construct the new $\mathcal{K}$, we simply replace $W^*$ by $S^*$.

Let $\psi : J_0 \rightarrow T_1^*$ be an isomorphism of $F_{20}$-modules and define
\[
\mathcal{T}_\psi = \{v + \psi(v) + u \mid v \in J_0, u \in T_1^{k-1}\}.
\]
Then $\mathcal{T}_\psi$ is normalized by $H$ and we define the new subgroup $\mathcal{H}$ of $G$ by
\[
\mathcal{H} = H \ltimes \mathcal{T}_\psi.
\]

**Theorem 5.2.** Let $\mathcal{H} = H \ltimes \mathcal{T}_\psi$, $\tilde{\mathcal{W}} = (\mathcal{W} \setminus W^*) \cup S^*$ and $\mathcal{K} = e^\mathcal{H} \cup (J_0 + \tilde{\mathcal{W}})$. Then the triple $(\mathcal{G}, \mathcal{H}, \mathcal{K})$ is a Bol loop folder such that the corresponding Bol loop is simple of exponent 2.

**Proof.** Again, the first statement follows from Proposition 3.5 and Lemma 4.3; one needs to verify hypothesis (a) and (d) of the Proposition only. Again (d) follows from $T_1 \cap T_1^* = 0$.

We prove (a) by showing that $K_0 = \mathcal{K} \cap \mathcal{H} \mathcal{I}$ is a transversal to $\mathcal{H}$ in $\mathcal{H} \mathcal{I}$. Since $K_0 \subset \mathcal{I}$, this is equivalent with the fact that $K_0 = J_0 + \tilde{\mathcal{W}}$ is a complement of the subspace
\[
\mathcal{H} \cap \mathcal{I} = H \cap J + \mathcal{T}_\psi
\]
in $\mathcal{I}$, i.e.
\[
K_0 + \mathcal{H} \cap \mathcal{I} = \mathcal{I}.
\]
In order to show this, we use the identities
\[
\mathcal{W} + \mathcal{T}_1 = \mathcal{W},
\]
\[
J_0 + \mathcal{T}_\psi = J_0 + \mathcal{T}_1,
\]
\[
J_0 + \mathcal{H} \cap \mathcal{I} = J_0 + H \cap J + \mathcal{T}_\psi
\]
\[
= J_0 + H \cap J + \mathcal{T}_1.
\]
Then
\[
J_0 + \mathcal{W} + \mathcal{H} \cap \mathcal{I} = J_0 + \mathcal{W} + H \cap J + \mathcal{T}_\psi
\]
\[
= J_0 + \mathcal{W} + H \cap J + \mathcal{T}_1
\]
\[
= J_0 + \mathcal{W} + H \cap J
\]
\[
= \mathcal{J},
\]
that is, $J_0 + \mathcal{W}$ is a complement to $\mathcal{H} \cap \mathcal{I}$ in $\mathcal{I}$ by the order argument $|J_0 + \mathcal{W}|/|\mathcal{H} \cap \mathcal{I}| = |\mathcal{I}|$.

We constructed \(\tilde{\mathcal{W}}\) from $\mathcal{W}$ by deleting the minimal submodule $W^*$ and replacing it by $S^*$. Therefore, it is enough to show that this deformations of $\mathcal{W}$ do not change the property of being a complement.
\[
J_0 + W^* + \mathcal{H} \cap \mathcal{I} = J_0 + W^* + H \cap J + \mathcal{T}_\psi
\]
\[
= H \cap J + J_0 + W^* + \mathcal{T}_1
\]
\[
= H \cap J + J_0 + W^* + T_1^* + \mathcal{T}_1
\]
\[
= J_0 + S^* + H \cap J + \mathcal{T}_\psi
\]
\[
= J_0 + S^* + \mathcal{H} \cap \mathcal{I}.
\]
This proves (a), hence \((\mathcal{G}, \mathcal{H}, \mathcal{K})\) is a Bol loop folder.

It remains to show that the Bol loop \(\mathcal{D}\) corresponding to \((\mathcal{G}, \mathcal{H}, \mathcal{K})\) is simple. Let us therefore assume that \(\mathcal{D} \rightarrow \mathcal{D}^2\) is a nontrivial surjective loop homomorphism and let \((\mathcal{G}^2, \mathcal{H}^2, \mathcal{K}^2)\) be the loop folder of \(\mathcal{D}^2\). Then we have a surjective homomorphism \(\alpha : \mathcal{G} \rightarrow \mathcal{G}^2\) with \(\alpha(\mathcal{H}) = \mathcal{H}^2\) and \(\alpha(\mathcal{K}) = \mathcal{K}^2\). Let \(\mathcal{N} = \ker \alpha\) and \(c^\sharp = \alpha(c) = c\mathcal{N}\). On the one hand, \(\mathcal{H}^2\) is core-free, thus,

\[
\text{core}_\mathcal{G}(\mathcal{H}^\mathcal{N}) = \mathcal{N}.
\]

On the other hand, \(\mathcal{N} \leq \mathcal{J}\) since otherwise \(\mathcal{H}\mathcal{N} = \mathcal{G}\) and \(\mathcal{D}^2 = 1\).

Let us first assume that \(J_0 \leq \mathcal{N}\). Since

\[
J_0 \cap \mathcal{J} \leq Z(\mathcal{G}/J_0) \triangleleft \mathcal{G}/J_0\text{ and } J_0 \mathcal{J} \leq \mathcal{H}\mathcal{N}/J_0,
\]

we have \(J \leq \mathcal{N}\) by [2]. In this case the image \(G^\sharp\) of \(G \leq \mathcal{G}\) is a homomorphic image of \(G/J \cong S_5\). Furthermore, if \([c^\sharp, c^g] = 1\) then \(c^\sharp c^g\) normalizes a Sylow 5-subgroup of \(G^\sharp\), thus, \(c^\sharp c^g\) is contained in a conjugate of \(\mathcal{H}^2\), and hence \(c^\sharp = c^g\) in this case. As the commuting graph of transpositions in \(S_5\) is connected, \(c^\sharp = c^g\) for all \(g\). This means \([c, \mathcal{G}] \leq \mathcal{N}\), contradicting to \(\mathcal{N} \leq \mathcal{J}\).

Let us now assume \(J_0 \nleq \mathcal{H}\) and let \(M\) be a minimal normal subgroup of \(\mathcal{G}\) contained in \(\mathcal{N}\). Then \(M \leq \soc(\mathcal{G}) = J_0 + \mathcal{W}\). Since \(J_0\) and \(W\) are non-isomorphic \(S_5\)-modules, \(J_0 + \mathcal{W}\) contains no submodules isomorphic to \(J_0\) and different from \(J_0\). This implies \(M \leq \mathcal{W}\) and, in particular, \(\mathcal{N} \cap \mathcal{W} \neq 0\).

Let us take an element \(s \in S^* \setminus W^* \subseteq \mathcal{K}\). As \(W^*\) and \(T_0^*\) are complements in \(U^*\), \(s \neq 0\) has the unique decomposition \(s = w + t\) with \(0 \neq w \in W^*\) and \(0 \neq t \in T_0^*\). Furthermore, for \(0 \neq j = \psi^{-1}(t) \in J_0\), \(j + t \in T_0^*\) holds. We claim that \(j + t \in \mathcal{N}\). Indeed, we have the decomposition

\[
w = (s + j) + (j + t), \quad s + j \in \mathcal{K}, j + t \in \mathcal{H}.
\]

If \(\mathcal{N} \leq U^*\) then \(M = W^*\) and \(\alpha(s + j) = \alpha(j + t) \in \mathcal{K}^2 \cap \mathcal{K}^2 = 1\). In particular, \(j + t \in \mathcal{N}\). If \(\mathcal{N} \nleq U^*\) then for an arbitrary element \(n \in (\mathcal{N} \cap \mathcal{W}) \setminus U^*, w + n \in \mathcal{K}\). This means that the element \(\alpha(w)\) has two \(\mathcal{K}^2\) decompositions:

\[
\alpha(w) = \alpha(w + n) + 0 = \alpha(s + j) + \alpha(j + t).
\]

This is only possible if \(j + t \in \mathcal{N}\), thus our claim is proved.

Let \(M'\) be the \(S_5\)-submodule generated by \(j + t\), then \(J_0 \leq M' \leq \mathcal{N}\) as the irreducible \(J_0\) is not \(S_5\)-isomorphic to a submodule of \(U^*\). This contradiction proves the simplicity of \(\mathcal{D}\).

\[\square\]

**Remark** We have seen that there are at least two possibilities for the choice of \(\mathcal{K}\). Also in \(\mathcal{W}\), we can replace any minimal submodule \(W^*\) by an appropriate \(S^*\). This shows that there are many Bol loops of exponent 2 which live in the same non-solvable group. Many of these loops are simple. Using computer calculations, we were able to construct over 30 nonisomorphic simple Bol loops of exponent 2 in \(\mathcal{G}\) in the case \(k = 1\).

In fact, this phenomena is not unusual for Bol loops of exponent 2. In [12, Section 5] and [16, Theorem 5.5], the authors constructed rich classes of Bol loops of exponent 2 having the same enveloping groups, namely the
wreath product $C_2^n \wr C_2$ and the extraspecial 2-group $E_{2n+1}^+$, respectively. In these cases, a simple parametrization of the conjugacy classes of involutions enabled a description of the associated loops. Unfortunately, the group $G$ has many conjugacy classes of involutions and these classes have no nice algebraic parametrization. Therefore, we see no way of classifying all simple Bol loops with enveloping group $G$.

The above remark lets us make another observation. While the class of finite Bol loops of exponent 2 is very rich, the structure of the right multiplication group of a Bol loop of exponent 2 is rather restricted. Differently speaking, while the classification of finite simple Bol loops of exponent 2 seems to be hopeless, we think that the classification of right multiplication groups of such loops could be a meaningful project.

We finish this paper with the following

**Question**  Classify those almost simple groups $T$ for which an exponent 2 Bol loop folder $(G, H, K)$ exists such that $T \cong G/O_2(G)$.
