ABSTRACT

Triple-negative breast cancer (TNBC) is a highly aggressive malignancy with limited treatment options due to its heterogeneity and the lack of well-defined molecular targets. In our endeavour towards the development of novel anti-TNBC agents, herein we report a one-pot three-component synthesis of novel spirooxindoles \(6a-p\), and evaluation of their potential anti-proliferative activity towards TNBC MDA-MB-231 cells. Spirooxindoles \(6a\), \(6e\) and \(6i\) emerged as the most potent analogues with IC\(_{50}\) = 6.70, 6.40 and 6.70 \(\mu\)M, respectively. Compounds \(6a\) and \(6e\) induced apoptosis in MDA-MB-231 cells, as evidenced by the up-regulation of the Bax and down-regulation of the Bcl-2, besides boosting caspase-3 levels. Additionally, \(6e\) displayed significant increase in the percent of annexin V-FITC positive apoptotic cells from 1.34 to 44\%. Furthermore, spirooxindoles \(6e\) and \(6i\) displayed good inhibitory activity against EGFR (IC\(_{50}\) = 120 and 150 \(\mu\)M, respectively). Collectively, these data demonstrated that \(6e\) might be a potential lead compound for the development of effective anti-TNBC agents.

Introduction

Breast cancer is the fifth most common cause of death in women worldwide. In fact, it represents about 12\% of all new cancer cases and 25\% of all cancers in women with nearly 1.7 million new cases diagnosed in 2012\(^1\). Routine breast cancer case showed an expression of three distinctive receptors which are oestrogen receptor (ER), progesterone receptor (PR) and human epidermal growth factor 2 receptor (Her2). About 15–20\% of the women diagnosed with breast cancer lacked in overexpression of these three receptors (ER, PR and Her2)\(^2\). This case is known as triple-negative breast cancer (TNBC) and it does not respond to normal protocol for the treatment of normal breast cancer. As a result, TNBC is responsible for high incident among the total percent of deaths regarded to breast cancer\(^3,4\). Unfortunately, TNBC patients were subjected to traditional cytotoxic therapies during their treatment protocol as till now there is no approved targeted cytotoxic drug for TNBC\(^5\).

On the other hand, spirooxindole is considered as a scaffold of interest to produce many derivatives with anticancer activity\(^6\). For example, Spirottryprostatins B (Figure 1), naturally isolated alkaloids from Aspergillus fumigatus, inhibit the cell cycle progression of tsFT210 cells at G2/M phase with IC\(_{50}\) = 14.0 \(\mu\)M\(^7\). Other synthetic spirooxindole derivative (MI-888) (Figure 1) in preclinical trials on xenograft models as mdm2-p53 inhibitor (\(K_{i}\) = 0.44 nM)\(^8\). Regarding cytotoxicity of some spirooxindole derivatives against TNBC cell lines, compound (i) (Figure 1) showed cytotoxic activity with IC\(_{50}\) = 11 \(\mu\)M against MDA-MB-231 cancer cell line\(^9\), while spirooxindole–pyranopyrimidine derivative (ii) (Figure 1) possessed cytotoxicity against MDA cell lines with IC\(_{50}\) = 6.9 \(\mu\)M\(^10\). Moreover, compound (iii) exhibited cytotoxic activity against ordinary breast cancer (MCF-7; IC\(_{50}\) = 8.6 \(\mu\)M) and TNBC (MDA-MB-231; IC\(_{50}\) = 6.4 \(\mu\)M)\(^11\) while compound (iv), Figure 1, displayed cytotoxicity against MDA-MB-231 with IC\(_{50}\) = 4.2 \(\mu\)M. Unfortunately, there is no trial till now to investigate the mechanism of action of spirooxindole derivative with cytotoxic activity against TNBC cell lines.

Based on the aforementioned findings and as a continuation of our research program on the development of novel effective anti-TNBC candidates\(^12-14\), it was thought worthwhile to extend our investigations to probe for novel spirooxindoles possessing promising anti-proliferative activity towards TNBC. In the present work we report the synthesis of a novel series of spirooxindoles \(6a-p\), Figure 1, and their in vitro efficacy against the proliferation of the aggressive TNBC MDA-MB-231 cell line. In addition, spirooxindoles were further investigated regarding their potential apoptotic induction and their effects on cell cycle progression in the MDA-MB-231 cancer cells to acquire a perception for the mechanism of the antitumor activity of target spirooxindoles. Since the epidermal growth factor receptor (EGFR) is frequently overexpressed in TNBC\(^15,16\), the most potent spirooxindoles in this study will be assayed for their potential inhibitory activity towards EGFR.

Chemistry

Melting points were measured with a Stuart melting point apparatus and were uncorrected. Infrared (IR) Spectra were recorded as KBr disks using Schimadzu FT-IR 8400 S spectrophotometer. Mass spectral data are given by GCMS-QP1000 EX spectrometer at 70 eV. NMR Spectra were recorded on a Varian Mercury NMR spectrometer. 1H spectrum was run at 400 MHz and 13C spectrum was run at 100 MHz in deuterated dimethylsulfoxide (DMSO-d6). Chemical shifts are expressed in values (ppm) using the solvent peak as internal standard. All coupling constant (J) values are given in hertz. The abbreviations used are as follows: s, singlet; d, doublet; m, multiplet. Elemental analyses were carried out at the Regional Center for Microbiology and Biotechnology, Al-Azhar University, Cairo, Egypt. Analytical thin layer chromatography (TLC) on silica gel plates containing UV indicator was employed routinely to follow the course of reactions and to check the purity of products. Some representative NMR charts are provided in the Supplementary material.

Synthesis of 3-oxo-3-phenylpropanenitriles (3)

To ethyl benzoates 2a-d (100 mmol) and acetonitrile (4.1 ml, 100 mmol) in dry benzene (250 ml) and dimethylformamide (10 ml), sodium hydride (4.8 g, 60%) was added. The reaction mixture was heated under reflux for 1 h then allowed to cool to room temperature. The solid formed was collected by filtration, washed with ether and dried. This solid was dissolved in water and then neutralized with conc. HCl to pH 7. The precipitated product was collected by filtration, washed with water and dried. Recrystallization from ethanol gave compounds 3.

Synthesis of 1-phenyl-3-(thiophen-2-yl)-1H-pyrazol-5-amine (5)

To a stirred solution of 3-oxo-3-(thiophen-2-yl)propanenitrile 4 (1.5 g, 10 mmol) and phenylhydrazine (1.96 ml, 2.16 g, 20 mmol) was added. The reaction mixture was heated under reflux for 1 h. The solid product obtained upon cooling was filtered off, washed with cold water and recrystallized from methanol to furnish compound 5 (yield 65%), m.p. 113–115°C; IR (KBr, ν cm⁻¹): 3351 (NH₂); 1H NMR (DMSO-d6) δ (ppm): 5.51 (s, 2H, NH₂), 5.86 (s, 1H, H4-pyrazole), 7.19 (t, 1H, H4-thiophene, J = 4.8 Hz), 7.34–7.65 (m, 7H, Ar-H); 13C NMR (DMSO-d6) δ ppm: 87.54, 123.48 (2C), 124.33, 125.23, 126.88, 127.99, 129.46 (2C), 137.54, 139.46, 146.38, 148.69; Anal. calcd. For C₁₃H₁₁N₃S: C, 64.71; H, 4.59; N, 17.41; Found C, 64.92; H, 4.54; N, 17.33.

General procedure for the synthesis of target compounds (6a–p)

A mixture of 1H-indole-2,3-diones 1a–d (1 mmol) with an equimolar amount of 3-oxo-3-phenylpropanenitriles 3a-d and 1-phenyl-3-(thiophen-2-yl)1H-pyrazol-5-amine 5 in 15 ml of HOAc/H₂O (1:1 v/v) at 120°C was stirred for 8–11 h (the reaction progress was monitored by TLC). Upon completion, the reaction mixture was cooled to room temperature. The solid formed was filtered, dried and crystallized from acetonitrile to produce compounds 6a–p.

2-Oxo-1',6'-diphenyl-3'-(thiophen-2-yl)-1',7'-dihydrospiro[indoline-3,4'-pyrazolo[3,4-b]pyridine]-5'-carbonitrile (6a)

Yield 68%, m.p. 295–297°C; IR (KBr, ν cm⁻¹): 3227 (NH), 2205 (C=O); 1H NMR (DMSO-d6) δ ppm: 6.21 (d, 1H, Ar-H, J = 2.8 Hz), 6.82 (dd, 1H, Ar-H, J = 4.8, 3.6 Hz), 6.92 (d, 1H, Ar-H, J = 8.0 Hz), 7.05 (t, 1H, Ar-H, J = 7.2 Hz), 7.29 (d, 1H, Ar-H, J = 7.6 Hz), 7.32 (d, 1H, Ar-H, J = 7.6 Hz), 7.40 (d, 1H, Ar-H, J = 5.2 Hz), 7.44–7.62 (m, 8H, Ar-H), 7.68 (d, 2H, Ar-H, J = 7.6 Hz), 10.45 (s, 1H, NH, D₂O exchangeable), 10.74 (s, 1H, NH, D₂O exchangeable); 13C NMR (DMSO-d6) δ ppm: 51.83, 83.74, 97.41, 110.47, 118.66, 123.28, 124.69 (2C), 125.44, 125.80, 126.98, 127.62, 128.44, 128.89, 129.35 (2C), 129.60, 129.90, 130.01 (2C), 130.99, 133.78, 134.48, 135.64, 138.00, 139.66, 141.70, 142.97, 151.53, 178.02 (C=O); MS m/z [%]: 497 [M⁺], 269.11, 77 [100]; Anal. calcd. Biological evaluation

In vitro anti-proliferative activity assay

Synthetic spiroxindoles 6a–p were tested for their anti-proliferative potency on TNBC cells (MDA-MB-231). Cells lines were maintained as monolayers in Dulbecco’s Modified Eagle’s Medium (DMEM) supplemented with 10% FBS, 2 mM l-glutamine, 100 μg/ml penicillin and 100 μg/ml streptomycin. Cells were sub-cultured with trypsin/EDTA solution, counted with haemocytometer and treated with trypsine/EDTA solution, counted with haemocytometer and plated onto 96-well plates (5000 cells/well) and left overnight to form a semi-confluent monolayer. We employed a modified method utilizing MTT (3-[4,5-dimethylthiazol-2-yl]-2,5-diphenyltetrazolium bromide dye (Carboxsyn, UK) that is based on the reduction of the dye by mitochondrial dehydrogenases of metabolically active cells to insoluble formazan crystals. Briefly, cell monolayers were treated in quadrates with vehicle (DMSO, 0.1% v/v), test samples or Adriamycin as positive control for an exposure time of 48 h. At the end of exposure, MTT solution in PBS (5 mg/ml) was then added to all wells including no cell blank and left to incubate for 90 min. The formation of formazan crystals was visually confirmed using phase contrast microscopy. DMSO (100 μl/well) was added to dissolve the formazan crystals with shaking for 10 min after which the absorbance was read at 590 nm against no cell blank on a FLuo Star Optima microplate reader (BMG Technologies, Germany). Cell proliferation was calculated comparing the OD values of the DMSO control wells and those of the samples represented as % proliferation to the control. Dose–response experiment was performed on samples producing ≥50% loss of cell proliferation using five serial 2-fold dilutions (50, 25, 12.5, 6.25 and 3.125 μM) of the sample. IC₅₀ values (concentration of sample causing 50% loss of cell proliferation of the vehicle control) were calculated using non-linear regression curve fitting of the growth versus concentration graph.
the dose response plots on GraphPad Prism V.6.0 software (Graphpad Inc, San Diego, CA). Assessment of morphological changes of MDA-MB-231 cells following treatment with the most active hits were performed using phase contrast inverted microscope (Carl Zeiss Microscopy GmbH, Göttingen, Germany) and photomicrographs were taken using digital camera.

In vitro cytotoxic activity WI-38 cells (human lung fibroblast normal cell line)

WI-38 cells (normal breast cells), were obtained from American Type Culture Collection. The cells were propagated in DMEM supplemented with 10% heat-inactivated FBS (Hyclone), 10 µg/ml of insulin (Sigma), and 1% penicillin-streptomycin. All of the other chemicals and reagents were from Sigma, or Invitrogen. Cytotoxicity was determined using MTT assay following a reported procedure. The 50% inhibitory concentration (IC50) was estimated from graphic plots of the dose response curve for each conc. using Graphpad Prism software (San Diego, CA).

Assay of the apoptosis markers (Bax, caspase-3 and Bcl-2) levels

The levels of the apoptotic markers (Bax, caspase-3) as well as the anti-apoptotic marker (Bcl-2) were assessed using ELISA colorimetric kits per the manufacturer’s instructions21,22. Cytotoxicity was determined using MTT assay following a reported procedure18. The 50% inhibitory concentration (IC50) was estimated from graphic plots of the dose response curve for each conc. using Graphpad Prism software (San Diego, CA).

EGFR kinase ELISA assay

EGFR enzyme inhibition was measured using a BPS Biosciences Colorimetric 96-well EGFR assay kit (catalog no. 40321), according to the manufacturer’s instructions. Percent inhibition was calculated by the comparison of compounds treated to control incubations. The concentration of the test compound causing 50% inhibition (IC50) was calculated from the concentration–inhibition response curve (triplicate determinations) and the data were compared with Erlotinib as standard EGFR inhibitor.

Results and discussion

Chemistry

The proposed synthetic routes to prepare the target compounds are shown in Scheme 1. Synthesis was initiated in Scheme 1 by reacting ethyl benzoates 2a–d and acetonitrile in dry benzene and DMF, in the presence of sodium hydride under reflux temperature to afford 3-oxo-3-phenylpropanenitrile 4 with phenylhydrazine in refluxing absolute ethyl alcohol. Preparation of the target spirooxindoles 6a–p was achieved via a one-pot three-component reaction of 1H-indole-2,3-diones 1a–d with an equimolar amount of 3-oxo-3-phenylpropanenitrile 4 and phenylhydrazine in refluxing absolute ethyl alcohol. Postulated structures of the newly synthesized spirooxindoles 6a–p were in full agreement with their spectral and elemental analyses data. IR spectra of the latter products displayed

Scheme 1. Synthesis of target compounds 6a–p; Reagents and conditions: (i) CH3CN, DMF, NaH, benzene, reflux 4 h; (ii) Ethanol, phenylhydrazine, reflux 1 h; (iii) HOAc/H2O (1:1 v/v), heating at 120 °C, 8–11 h.
absorption bands of the (NH) groups in the region 3205–3387 cm\(^{-1}\), in addition to the carbonyl bands in the region 1709–1716 cm\(^{-1}\) and C\(\equiv\)N bands in the region 2202–2206 cm\(^{-1}\). \(^1\)H NMR spectra of 6a–p showed two singlet D\(_2\)O-exchangeable signals attributable to two (NH) protons at range \(\delta\) 10.09–10.52 and 10.45–10.89 ppm. In addition, the methoxy (-OCH\(_3\)) protons of compounds 6c, 6g, 6k and 6m–p were displayed as singlet signals in the range \(\delta\) 3.68–3.81 ppm, whereas, the methyl (-CH\(_3\)) protons of compounds 6b, 6f, 6j and 6n appeared as singlet signals around \(\delta\) 2.35 ppm. Moreover, \(^{13}\)C NMR spectra of spirooxindoles 6a–p showed signals resonating in the range \(\delta\) 177.72–178.10 ppm attributable for the carbon of the carbonyl (C=O) groups, whereas the carbons of the methoxy (-OCH\(_3\)) groups of compounds 6g, 6k and 6m–o and carbons of the methyl (-CH\(_3\)) groups of compounds 6b, 6j and 6n appeared as two signals around \(\delta\) 56.0 and 21.4 ppm, respectively.

### Biological evaluation

#### In vitro anti-proliferative activity

The in vitro anti-proliferative activity of the newly synthesized spirooxindoles 6a–p was examined against TNBC MDA-MB-231 cells. This assay was performed utilizing the 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) colorimetric assay as described by Mosmann\(^{18}\). Adriamycin was included in this assay as a reference drug. The results were expressed as median growth inhibitory concentration (IC\(_{50}\)) values that represent the compounds concentrations required to afford a 50% inhibition of cell growth after 48 h of incubation, compared to untreated controls (Table 1).

As shown in Figure 2, morphological assessment using bright field phase contrast microscopy revealed adverse effects on cell morphology such as monolayer disruption in addition to cell shrinkage and rounding, as indicated by arrows.

From the obtained results, it was obvious that various prepared spirooxindoles displayed excellent to modest growth inhibitory activity against MDA-MB-231 cells. Spirooxindoles 6a, 6e and 6i emerged as the most potent analogues towards MDA-MB-231 cells through this study with IC\(_{50}\) = 6.70, 6.40 and 6.70 \(\mu\)M, respectively. Besides, compounds 6d, 6f, 6h, 6j, 6k and 6m were moderately active against MDA-MB-231 cells with IC\(_{50}\) range (12.00–18.20 \(\mu\)M). While, spirooxindoles 6b, 6c, 6g and 6l

\(^*\)NA: Compounds having IC\(_{50}\) value >50 \(\mu\)M.
possessed weak anti-proliferative activity against MDA-MB-231 cells (IC_{50} = 29.70, 37.80, 24.10, and 30.60 μM, respectively), compounds 6n–p did not display growth inhibitory activity against MDA-MB-231 cells.

**Structure activity relationship (SAR)**

Based on the aforementioned results of the biological anti-proliferative activity assay, important structure activity relationships could be deduced. Firstly, we investigated the impact of the C-5 substitution of the indoline moiety. The abolished activity of 5-methoxyindoline derivatives 6n–p along with the decreased IC_{50} value of 6m, with incorporated unsubstituted phenyl group, (17.50 μM) than that of its corresponding members 6a, 6e and 6i, with unsubstituted, 5-chloro substituted and 5-bromo substituted indoline moiety, (6.70, 6.40 and 6.70 μM, respectively) indicated that unsubstitution or C-5 substitution of the indoline moiety with electron withdrawing groups (EWGs), as 5-Cl or 5-Br, is more beneficial than incorporation of electron-donating substituents, as 5-OCH₃, to the growth inhibitory activity against MDA-MB-231 cells.

We then examined the effect of the substitution of the pendant phenyl group at C-6 of pyrazolo[3,4-b]pyridine moiety on the prepared spirooxindoles activities. Incorporation of unsubstituted phenyl group led to compounds 6a (IC_{50} = 6.70 μM), 6e (IC_{50} = 6.40 μM), 6i (IC_{50} = 6.70 μM) and 6m (IC_{50} = 17.50 μM) with superior activity to their corresponding 4-substituted-phenyl analogous 6c–d (IC_{50} range: 12.00–37.80 μM), 6f–h (IC_{50} range: 16.60–24.10 μM), 6j–l (IC_{50} range: 12.70–30.60 μM) and 6n–p (IC_{50} > 50 μM) against MDA-MB-231 cells, implying that incorporation of unsubstituted phenyl group is indispensable for the anti-proliferative activity.

Finally, we can deduce that the substitution pattern over the synthesized spirooxindoles is a crucial element for the anti-proliferative activity towards TNBC MDA-MB-231 cell line. Incorporation of unsubstituted or 5-EWG-substituted indoline moiety along with unsubstituted phenyl group at C-6 of pyrazolo[3,4-b]pyridine moiety greatly enhances the growth inhibitory activity of the target spirooxindoles 6a–p.

**In vitro cytotoxicity towards human normal WI-38 cells**

Three potent compounds 6a, 6e and 6i were evaluated for their ability to induce cytotoxic effect against human normal lung fibroblast cell line (WI-38 cells), to investigate their safety adopting the ability to induce cytotoxic effect against human normal lung fibroblast cell line (WI-38 cells), to investigate their safety adopting the in vitro cytotoxicity assay. The compounds were selected based on their safety, as indicated by their IC_{50} values, and their ability to induce cytotoxicity against human normal lung fibroblast cells (WI-38 cells).

**Apoptosis induction in TNBC MDA-MB-231 cells**

Apoptosis is a programmed routine that proves to be an essential physiological process for tissue development, immune response, redundant cells clearance and homeostasis by which cells signal their own termination. Accordingly, cellular integrity is conserved by this finely tuned, self-automated death. Consequently, the success of cancer cells to proliferate unconditionally is allied to its ability to halt apoptosis. Thus, targeting apoptosis induction is a successful strategy for combating tumour progression.

To further elucidate the mechanism of cell death induced by the target spirooxindoles and as a part of our ongoing efforts to develop novel pro-apoptotic agents, we evaluated ability of compounds 6a and 6e on the level of caspase-3 to provoke apoptosis in MDA-MB-231 cells through determination of the hallmark parameters of apoptosis.

**Effects on the levels of active caspase-3**

Caspases, a family of cysteineaspatic proteases, are the crucial apoptosis mediators that provide essential links in cell regulatory networks controlling cell death. Caspase-3 is the key executioner caspase which modifies proteins ultimately responsible for apoptosis. Accordingly, the effect of spirooxindoles 6a and 6e on the level of caspase 3 was evaluated, to give insight to the pro-apoptotic effect of the prepared spirooxindoles (Table 3).

Results in Table 3 showed that treatment of MDA-MB-231 cells with compounds 6a and 6e resulted in a significant elevation in the level of active caspase-3 by about 31.5 and 36.5 folds, respectively, compared to control.

**Effects on mitochondrial apoptosis pathway (Bcl-2 family) proteins**

Bcl-2 family comprises a group of crucial regulatory factors in apoptosis that finely tune the apoptotic switch on/off mechanism. Based on their functional and structural criteria, the members are divided into two major classes: group I proteins that are anti-apoptotic and group II proteins that are apoptotic. Group I anti-apoptotic proteins exert their function by inhibiting group II apoptotic proteins through simply binding to them. Group I proteins bind selectively to the active conformations of group II proteins to prevent them from being inserted into the mitochondria and thus cease the release of pro-apoptotic factors such as cytochrome c, ultimately aborting apoptosis. Thus, the inhibition of group I proteins and/or the activation of group II proteins can successfully induce apoptosis. Herein, we evaluated the effect of compounds 6a and 6e on the level of Bcl2, as a representative group I member, and the level of Bax, as a representative group II member (Table 3).

As presented in Table 3 compound 6a induced the protein expression of Bax with 50.8 folds of the control while 442.1 folds were recorded with compound 6e. Parallel to this, the protein expression of the antiapoptotic marker Bcl-2 was down-regulated to 14.7% compared to that of the basal level in the control by compound 6a while compound 6e produced down-

### Table 2. In vitro cytotoxicity activity of compounds 6a, 6e and 6i against WI-38 cells, and Selectivity index for the tested compounds.

| Compound | IC_{50} (μM) | Selectivity Index |
|----------|--------------|------------------|
|          | WI-38        | MDA-MB-231       |                  |
| 6a       | 78.1         | 6.7              | 11.7             |
| 6e       | 43.2         | 6.4              | 6.8              |
| 6i       | 39.3         | 6.7              | 5.9              |

### Table 3. Effect of compounds 6a and 6e on the active caspases-3 level, and the expression levels of Bcl-2 and Bax in MDA-MB-231 cancer cells treated with each compound at its IC_{50} concentration.

| Comp. | Caspase-3 (ng/ml) | Bax (ng/ml) | Bcl-2 (ng/ml) |
|-------|------------------|-------------|---------------|
| 6a    | 0.3501 (31.5)    | 405.5 (506.8) | 0.3958 (0.147) |
| 6e    | 0.4058 (36.5)    | 353.7 (442.1) | 0.7449 (0.276) |
| Control | 0.0111           | 0.80        | 2.692         |

*Numbers given between parentheses are the number of folds of control.*
various phases of cell cycle can be detected upon treatment of cancer cells with anticancer agents. Compound 6e was investigated for its activity to disrupt the cell cycle of MDA-MB-231 cancer cell lines. This effect was illustrated by DNA flow cytometric analysis which MDA-MB-231 cells was treated with compound 6e at concentration equals to the IC50 for 24 h. Figure 3 showed that compound 6e expressed significant decrease in the G0-G1 phase by approximately 0.5 folds related to the control. Compound 6e displayed no significant change in the S phase while G2-M phase was arrested by 2.65 folds with 19.1% with respect to control (7.2%). Alteration of the Pre-G phase and arrest of G2-M phase were significant remarks for compound 6e to induce apoptosis.

**Annexin V-FITC apoptosis assay**

Externalization of the phospholipid phosphatidylserine at the cell membrane is a one of the well-recognized hallmarks of cells going into apoptosis. In our study, the apoptotic effect of compound 6e was further assessed by Annexin V-FITC/PI (AV/PI) dual staining assay to examine the occurrence of phosphatidylserine externalization and also to comprehend whether cell death is due to physiological apoptosis or nonspecific necrosis (Figure 4).

Flow cytometric analysis revealed that MDA-MB-231 cells treated with compound 6e displayed a significant increase in the percent of annexin V-FITC positive apoptotic cells (UR + LR) from 1.34% to 44% which comprises about 32.8 folds compared to control.

In conclusion, the enhanced expression of the pro-apoptotic protein Bax and the reduced expression of the anti-apoptotic protein Bcl-2 as well as the up-regulated active caspase-3 level together with a harmonized increase in the Bax/Bcl-2 ratio, highlighted that the anti-proliferative activity of the target spirooxindoles 6 might be attributed, at least in part, to the induction of the intrinsic apoptotic mitochondrial pathway.

**In vitro EGFR kinase ELISA assay**

On account of its overexpression in a significant number of TNBC, epidermal growth factor receptor (EGFR) emerged as an attractive target for developing effective therapeutic strategies for treatment of TNBC patients. In this study the most potent anti-proliferative spirooxindoles 6a, 6d, 6e and 6i–k were selected to evaluate their potential inhibitory activity against EGFR by use of a colorimetric Enzyme-Linked Immunosorbent Assay (ELISA). Erlotinib, a clinically used EGFR inhibitor, was taken as the reference drug. The results were reported as a 50% inhibition concentration values (IC50) which determined as triplicate determinations from the standard curve and summarized in Table 4.

Results revealed that the tested compounds exhibited EGFR inhibitory activity with IC50 values ranging from 0.12 to 0.51 µM. Compound 6i emerged as the most potent EGFR inhibitor in this study that showed comparable potency (IC50 = 0.12 ± 0.01 µM) to the reference drug Erlotinib (IC50 = 0.11 ± 0.01 µM). Besides, compound 6e displayed good activity (IC50 = 0.15 ± 0.02 µM).
Conclusions

In summary, we have synthesized a novel series of sixteen spirooxindoles 6a–p through a one-pot three-component reaction, with the prime aim of developing potent anti-TNBC agents. All the newly synthesized spirooxindoles 6a–p was evaluated for their in vitro anti-proliferative activity towards TNBC MDA-MB-231 cells. Spirooxindoles 6a, 6e and 6i were the most potent members against MDA-MB-231 cells with IC_{50} = 6.70, 6.40 and 6.70 μM, respectively. Besides, compounds 6d, 6f, 6h, 6j, 6k and 6m were moderately active against MDA-MB-231 cells with IC_{50} range (12.00 – 18.20 μM). Moreover, the cytotoxicity of the active counterparts 6a, 6e and 6i was examined against normal human cell line (WI-38 lung fibroblast) where none of them displayed significant cytotoxic effect, thereby providing a good safety profile. Subsequently, 6a and 6e were further estimated for their apoptosis induction potential. Both proved to induce apoptosis, which evidenced via the reduced expression of the anti-apoptotic protein Bcl-2 in addition to the enhanced expression of the pro-apoptotic protein Bax as well as the up-regulated active caspase-3 level. Moreover, 6e displayed a significant increase in the percent of annexin V-FITC positive apoptotic cells from 1.34% to 44% which comprises about 32.8 folds compared to control. As the EGFR is frequently overexpressed in TNBC, six potent spirooxindoles was assayed for their potential inhibitory activity towards EGFR. Compounds 6e and 6i displayed potent inhibitory activity against EGFR with IC_{50} values of 120 and 150 nM, respectively.

Table 4. IC_{50} values for the inhibitory activity of spirooxindoles 6a, 6d, 6e and 6i–k against – EGFR.

| Compound | IC_{50} (μM)\textsuperscript{a} |
|----------|------------------|
| 6a       | 0.43 ± 0.04      |
| 6d       | 0.36 ± 0.02      |
| 6e       | 0.15 ± 0.02      |
| 6i       | 0.12 ± 0.01      |
| 6j       | 0.51 ± 0.04      |
| 6k       | 0.31 ± 0.02      |
| Erlotinib| 0.11 ± 0.01      |

\textsuperscript{a}IC_{50} values are the mean ± SD of three separate experiments.
