(Dated: November 25, 2021)

We construct product formulas for exponentials of commutators and explore their applications. First, we directly construct a third-order product formula with six exponentials by solving polynomial equations obtained using the operator differential method. We then derive higher-order product formulas recursively from the third-order formula. We improve over previous recursive constructions, reducing the number of gates required to achieve the same accuracy. In addition, we demonstrate that the constituent linear terms in the commutator can be included at no extra cost. As an application, we show how to use the product formulas in a digital protocol for counterdiabatic driving, which increases the fidelity for quantum state preparation. We also discuss applications to quantum simulation of one-dimensional fermion chains with nearest- and next-nearest-neighbor hopping terms, and two-dimensional fractional quantum Hall phases.

I. INTRODUCTION

Product formulas approximate a desired unitary operator with a product of simpler operator exponentials. As a practical tool, product formulas are widely used in quantum simulation of condensed matter models and quantum chemistry problems [1–9], as well as quantum Monte Carlo and statistical physics problems [10–13]. The simplest example is the first-order Lie-Trotter product formula

\[ e^{xA}e^{xB} = e^{x(A+B)} + O(x^2), \]  

which approximates the sum of operators $A$ and $B$. From the perspective of quantum simulation, this provides a way to approximate the time evolution of the Hamiltonian $H = A + B$ by multiplying elementary exponentials of the form $e^{-\delta A}$ and $e^{-\delta B}$ (which generally do not commute).

In addition to simulating Hamiltonian evolution of a linear combination of terms, one can also construct product formulas for commutators [14, 15]. The simplest product formula for commutators is the second-order formula

\[ S_2(x) := e^{xA}e^{xB}e^{-xA}e^{-xB} = e^{x^2[A,B]} + O(x^3). \]  

arXiv:2111.12177v1  [quant-ph]  23 Nov 2021
Such commutator product formulas raise the possibility of simulating complicated unitaries on a quantum simulator using limited native gates: given the time evolution of operators $A$ and $B$, the time evolution of any linear combination of nested commutators involving $A$ and $B$ (i.e., the Lie algebra generated by $A$ and $B$) can be simulated. Moreover, product formulas for commutators with arbitrary high order $k$, $\exp([A,B]x^2) + O(x^{k+1})$, have been constructed recursively [14, 15].

Now we introduce terminology for product formulas. An $m$th-order product formula for $A$ and $B$ is a sequence of elementary exponentials of $A$ and $B$ that approximates $e^{x[A,B]}$ to $m$th order:

\[
\sum_{i=0}^{m} x^i A^i e^i B e^{i+1} A e^{i+2} B \ldots = e^{x[A,B]} + O(x^{m+1}),
\]

(4)

where the time interval for the $i$th elementary exponential is $t_i := \alpha_i x$ and $\alpha_1, \alpha_2, \alpha_3, \alpha_4, \ldots$ are parameters that define the formula. Similarly, an $m$th-order commutator product formula is a sequence of elementary exponentials of $A$ and $B$ that approximates $e^{x^2[A,B]}$ to $m$th order:

\[
e^{t_1 A} e^{t_2 B} e^{t_3 A} e^{t_4 B} \ldots = e^{x^2[A,B]} + O(x^{m+1}).
\]

(3)

Notice that the prefactor of $[A,B]$ is $x^2$ since it arises from terms quadratic in $t_i = \alpha_i x$. Both sum and commutator product formulas can be represented as quantum circuits, as shown in Fig. 1(a). In general, directly determining suitable coefficients $\alpha_i$ is difficult. Ref. [13] provides an operator differential method for computing the coefficients of commutator product formulas, but it is hard to solve the resulting polynomial equations.

High-order product formulas can be constructed recursively. In this approach, we choose an invertible product formula $f_m(x)$ as the base formula and recursively increase accuracy with some prescribed sequence of terms of the form $f_m(v_i x)$ and $f_m(v_i x)^{-1}$ for appropriate coefficients $v_i$. By iterating this procedure, we can produce an arbitrarily high-order approximation of the target exponential. Thus the recursive method can be viewed as a “product formula of product
formulas” where a lower-order product formula is the elementary unit. We call such a recursive formula \(p\)-copy if it uses \(p\) elementary formulas \(f_m\) and \(f_m^{-1}\) to improve the order by 1. We also consider recursive constructions that use \(q\) elementary formulas \(f_m\) and \(f_m^{-1}\) to improve the order by 2, which we call a \(\sqrt{q}\)-copy recursive formula.

See Table II for a comparison of directly constructed product formulas and recursive formulas. Given an \(m\)-th order product formula \(f_m\) that uses \(N_m\) elementary gates, the recursive construction gives an \((m+1)\)-st order product formula \(f_{m+1}\) with \(N_{m+1} = pN_m - O(p)\) gates,\(^1\) as shown in Fig. 1(b). Starting from an \(m\)-th order product formula, we can apply the recursive formula \(k\) times to get an \((m + k)\)th-order product formula.

For practical quantum computation, it is essential to find product formulas that are as efficient as possible. Previous recursive constructions can perform better when using \(q\) elementary unit native gates \(\epsilon^{A_1}_i \epsilon^{B_1}_i \ldots \epsilon^{A_mB}_m\). 

### Summary of results

In this work, we use the operator differential method \([13]\) to construct product formulas that combine sums and commutators. Specifically, as described in Sec. II and Appendix A, we construct a formula that implements

\[
e^{x(A+B)}R e^{xA}B e^{xA}e^{xB} + O(x^4)
\]

for arbitrary \(R \in \mathbb{R}\), using 6 exponentials of \(A\) and \(B\).

In the large-\(R\) limit, our product formula reduces to the pure commutator formula

\[
S_3(x) := e^{\frac{\sqrt{2} a}{2} x A} e^{\frac{\sqrt{2} a}{2} x B} e^{-\frac{\sqrt{2} a}{2} x A} e^{-\frac{\sqrt{2} a}{2} x B} = e^{x [A,B]} + O(x^4),
\]

which reduces the error by one order in \(x\) as compared to the group commutator formula Eq. (2), giving substantially better performance in practice.

In a recursive construction of higher-order product formulas, a good base formula can have significant impact. We show that the third-order commutator product formula \(S_3(x)\) can improve recursive methods. We numerically check that previous recursive constructions can perform better when using \(S_3(x)\) instead of \(S_3(x)\) as the base formula. In particular, this change significantly reduces the total gate count required to achieve a fixed error.

In addition to a better base formula, we improve the recursive method. We first modify the Childs-Wiebe \(\sqrt{b}\)-copy formula (Theorem 2 in Ref. [15]), which uses 6 instances of an even-order formula \(f_{2k}\) to increase its order by 2. This construction first applies a 2-copy recursive formula to increase

\[
N_m\text{-gate } m\text{-th-order product formula}
\]

\[
p\text{-copy recursive product formula}
\]

| explicit form | \(f_m(x) = e^{x_1 A_1} e^{x_2 A_2} \ldots e^{x_m A_m}\) | \(f_{m+1}(x) = f_m(v_1 x)^{\frac{1}{p}} f_m(v_2 x)^{\frac{1}{p}} \ldots f_m(v_p x)^{\frac{1}{p}}\) |
| elementary unit | native gates \(\epsilon^{A_1}_i \epsilon^{B_1}_i \ldots \epsilon^{A_mB}_m\) | a product formula \(f_m(x)\) and inverse formula \(f_m(x)^{-1}\) |
| number of gates | \(N_m\) | \(pN_m - O(p)\) |
| error | \(O(x^{m+1})\) | \(O(x^{m+2})\) |
| parameters | \(\alpha_1, \alpha_2, \ldots, \alpha_n\) | \(v_1, v_2, \ldots, v_p\) |

---

1. When we multiply adjacent terms \(f_m\) and \(f_m^{-1}\) in the recursive formula, two gates in the middle may combine into a single gate if they are both exponentials of the same operator. In the best case, the number of gates is \(N_{m+1} = pN_m - (p - 1)\).
2. The number of linearly independent commutators involving \(p\) copies of \(A\) or \(B\) is \(2^p - 2\) if \(p\) is a prime \([16, 17]\). Canceling this many terms generically requires a number of parameters that is exponential in \(p\).

\[
\{\sigma^z_2 \sigma^z_4, \sigma^z_2 \sigma^h_2\} = -2i \sigma^y_2 \sigma^y_2 \sigma^h_2.
\]  

(5)

More generally, we can construct multi-spin operators from lower order terms. Furthermore, the commutator between two bosonic or fermionic nearest-neighbor hopping terms is a next-nearest-neighbor hopping term:

\[
[a_i^\dagger a_j + a_j^\dagger a_i, a_k^\dagger a_j + a_j^\dagger a_k] = a_i^\dagger a_k - a_k^\dagger a_i,
\]

(6)

where \(a_i, a_i^\dagger\) are bosonic or fermionic creation and annihilation operators that obey \([a_i, a_j^\dagger]\) = \(\delta_{i,j}\). This technique can be used to generate complicated interactions from simple nearest-neighbor interactions. In Fig. 1(c), we show the construction of next-nearest-neighbor hopping in a 1d system using a commutator. We show a similar approach to next-nearest-neighbor hopping for a 2d system in Fig. 1(d).
the order from $2k$ to $2k + 1$ and then applies a 3-copy recursive formula to get a $(2k + 2)$nd-order product formula. We observe that these two steps can be decomposed. In particular, if we start with an odd-order product formula, we can apply the 3-copy recursive formula first and then apply the 2-copy one. This modified Childs-Wiebe $\sqrt{6}$-copy formula is denoted $V$ in Table II.

We further propose $\sqrt{4}$-copy, $\sqrt{5}$-copy, and $\sqrt{10}$-copy recursive formulas that use $(4N_m - 3)$, $(5N_m - 4)$, and $(10N_m - 4)$ gates, respectively, to generate $(m + 2)$nd-order formulas from an $N_m$-gate $m$th-order formula. Note that using fewer gates to achieve a given order is not necessarily better, since constant factors in the error terms can significantly affect performance. Indeed, using numerical simulations, we demonstrate that our $\sqrt{10}$-copy recursive formula requires the fewest gates to reach the same accuracy.

In summary, we find that:

1. The third-order product formula $S_3(x)$ (Eq. (8)) performs better than the standard choice $S_2(x)$ (Eq. (2)), serving as a better base formula for all recursive methods in Table II.

2. Other recursive formulas can offer better performance, with the $\sqrt{10}$-copy formula performing the best of those we study.

We present two concrete applications of our product formulas. The first application is in the context of the counterdiabatic driving, a method that was originally proposed for analog quantum computation using nested commutators [18–21]. In the context of digital quantum state preparation, we demonstrate that our product formulas can generate the commutator terms required for counterdiabatic driving. This additional term increases the fidelity of the final state without increasing the number of gates. To illustrate the efficiency of our approach, we consider state preparation for spins as an example.

The second application is in the context of the quantum simulation. We show that a one-dimensional fermion chain with next-nearest-neighbor hopping terms and a model of two-dimensional fractional quantum Hall phases can be naturally simulated using our method. In both cases, we use nearest-neighbor hopping terms to generate next-nearest-neighbor hopping terms, which break time-reversal symmetry.

The remainder of the paper is organized as follows. In Sec. II, we use the operator differential method to construct the third-order commutator product formula. In addition, we propose a new kind of product formula for combined sums and commutators in Sec. II B. Then we derive recursive product formulas for commutators in Sec. III. We present numerical simulations of the third-order product formula and recursive constructions in Sec. IV. Next, in Sec. V A, we demonstrate that this new formula can implement counterdiabatic driving and generate next-nearest-neighbor interactions from nearest-neighbor terms. We show how to simulate a 1d fermion chain with next-nearest-neighbor hopping terms in Sec. VB and fractional quantum Hall phases (the Kapit-Mueller model) in Sec. V C. Finally, we discuss open questions and future directions in Sec. VI.

II. THIRD-ORDER PRODUCT FORMULA

In this section, we introduce the third-order exponential product formula, i.e., a formula with error $O(x^4)$ where each elementary exponential has time proportional to $x$. We first present a formula for the pure commutator $[A, B]$ and then present a product formula that includes both the sum $A + B$ and commutator $[A, B]$.

We derive these product formulas using the operator differential method [13], as detailed in Appendix A. In particular, we find the following general expression for a 6-gate product formula:

$$e^{p_1 A} e^{p_2 B} e^{p_3 A} e^{p_4 x B} e^{p_5 A} e^{p_6 x B} = \exp(\Phi(x))$$  \hspace{1cm} (9)

with

$$\Phi(x) = x(1A + mb) + \frac{x^2}{2}(lm - 2q)[A, B]$$
$$\frac{x^3}{6}\left(\frac{l^2 m}{2} - 3r\right)[A, [A, B]]$$
$$+ \frac{m^2}{2} - 3s\right)[B, [B, A]]$$
$$+ O(x^4)$$  \hspace{1cm} (10)
where
\[
\begin{align*}
l &:= p_1 + p_3 + p_5, \\
m &:= p_2 + p_4 + p_6, \\
q &:= p_2p_3 + p_2p_5 + p_4p_5, \\
r &:= p_1p_2p_3 + p_1p_2p_5 + p_1p_4p_5 + p_3p_4p_5, \\
s &:= p_2p_3p_4 + p_2p_3p_6 + p_2p_5p_6 + p_4p_5p_6. \\
\end{align*}
\]

Thus an arbitrary 6-gate product formula \( \Phi(x) \) can be reparameterized by \( l, m, q, r, s \) which are functions of \( p_1, \ldots, p_6 \). By fine-tuning the parameters \( p_1, \ldots, p_6 \) (or equivalently, \( l, m, q, r, s \)), we can obtain the desired \( \Phi(x) \). Here we focus on two cases: a third-order commutator product formula and a third-order product formula for a combination of the sum and commutator.

To construct a third-order product formula for the commutator, we solve for \( p_1, \ldots, p_6 \) so that
\[
\begin{align*}
l &= m = 0, \\
lm - 2q &= 0, \\
\frac{l^2m}{2} - 3r &= \frac{m^2l}{2} - 3s = 0. \\
\end{align*}
\]

These conditions ensure \( \Phi(x) \) only involves the commutator \([A, B]\) and terms that are \( O(x^4) \).

Similarly, for the third-order product formula for both sum and commutator, we would like to keep both the linear and (non-nested) commutator terms. Hence we should find \( p_1, \ldots, p_6 \) so that
\[
\begin{align*}
l &= m \neq 0, \\
lm - 2q &= 0, \\
\frac{l^2m}{2} - 3r &= \frac{m^2l}{2} - 3s = 0. \\
\end{align*}
\]

We discuss the details in Sec. II A (pure commutator) and Sec. II B (sum and commutator).

### A. Pure commutator

We now derive the 6-gate third-order product formula for commutators:
\[
S_3(x) := \exp\left(\frac{\sqrt{5} - 1}{2}xA\right) \exp\left(\frac{\sqrt{5} - 1}{2}xB\right) \exp(-xA) \\
\cdot \exp\left(-\frac{\sqrt{5} + 1}{2}xB\right) \exp\left(\frac{3 - \sqrt{5}}{2}xA\right) \exp(xB) \\
= \exp(x^2[A, B] + O(x^4)).
\]

This formula can be checked by using the Taylor series of each term up to order \( x^3 \) to show that the constant, \( x \), \( x^2 \), and \( x^3 \) terms on both sides agree. In general, by Eq. (10), the product formula
\[
e^{p_1xA}e^{p_2xB}e^{p_3xA}e^{p_4xB}e^{p_5xA}e^{p_6xB} \\
= \exp(x^2[A, B] + O(x^4))
\]

holds if \( p_1, p_2, p_3, p_4, p_5, p_6 \) satisfy the following polynomial equations resulting from Eq. (12):
\[
\begin{align*}
l &= m = r = s = 0, \\
q &= p_2p_3 + p_2p_5 + p_4p_5 = -1. \\
\end{align*}
\]

Eq. (14) is a particular solution of the above equations. Fig. 2 shows the empirical error scaling behavior of \( S_3(x) \) for a 1-qubit example. The error exponent obtained by fitting the data points in the interval \( 2 \times 10^{-2} \leq x \leq 10^{-1} \) is 4.001, in good agreement with theory.

### B. Sum and commutator

In this section, we consider the product formula for both sum and commutator. For arbitrary \( R \in \mathbb{R} \), we want to find a set of parameters \( p_1(R), \ldots, p_6(R) \) such that
\[
\Phi(x) = x(A + B) + R x^2[A, B] + O(x^4).
\]

This is equivalent to solving the equations given by Eq. (13):
\[
\begin{align*}
l &= m = 1, \\
q &= -R + \frac{1}{2}, \\
r &= s = \frac{1}{6}. \\
\end{align*}
\]

These equations are in general difficult to solve analytically, but one can find an approximate solution for large \( R \):
\[
\begin{align*}
p_1 &= (g - 1) \sqrt{R + \frac{1}{2}}, \quad p_2 = (g - 1) \sqrt{R + \frac{1}{2} + 1}, \\
p_3 &= - \sqrt{R + \frac{1}{2} + 1}, \quad p_4 = -g \sqrt{R + \frac{1}{2}}, \\
p_5 &= (2 - g) \sqrt{R + \frac{1}{2}}, \quad p_6 = \sqrt{R + \frac{1}{2}}. \\
\end{align*}
\]
where \( g := \frac{\sqrt{2} + 1}{2} \). This choice corresponds to
\[
\begin{align*}
  l &= m = 1, \\
  q &= -R + \frac{1}{2}, \\
  r &= -(g - 1) \left( R + \frac{1}{2} - \sqrt{R + \frac{1}{2}} \right), \quad (20) \\
  s &= (g - 1) \left( R + \frac{1}{2} - \sqrt{R + \frac{1}{2}} \right).
\end{align*}
\]

While this does not satisfy \( r = s = \frac{1}{2} \), the leading order of \( r \) and \( s \) is \( O(R) \) (whereas for a general choice of \( \{ p_i \} \), the leading order is \( O(R^2) \)). Substituting Eq. (20) into Eq. (10), we find that the linear term vanishes, the quadratic term is
\[
\frac{ln - 2q}{2} x^2 [A, B] = R x^2 [A, B], \quad (21)
\]
and the \( x^3 \) term is
\[
\frac{x^3}{6} \left( \frac{l^2 m}{2} - 3r \right) [A, [A, B]] + \left( \frac{m^2 l}{2} - 3s \right) [B, [B, A]].
\]

From Eq. (10), we have constructed
\[
\begin{align*}
  f_R(x) &= \exp \left[ x (A + B) + R x^2 [A, B] \right. \\
  & \quad + x^3 O(R) + x^4 O(R^2) + \cdots \quad (23) \\
  & \quad + x^k O(R^{k+1}) + \cdots\right].
\end{align*}
\]

Notice that the coefficient in front of the \( x^k \) term for \( k \geq 4 \) contains products of \( p_{i_1}, p_{i_2} \cdots p_{i_k} \), where each \( p_{i_j} \) is \( O(R^2) \).

We then use the third-order product formula to implement a new gate from existing gates. Assume we can perform gates of the form \( e^{2\beta A} \) and \( e^{2\beta B} \) for \( \beta_1, \beta_2 \in \mathbb{R} \) and our goal is to perform
\[
e^{\alpha(A+B)+\beta[A,B]} \quad (24)
\]
for some desired \( \alpha, \beta \in \mathbb{R} \). First, we pick a large integer \( n \) such that \( x := \frac{\alpha}{n} \) is small and \( R := \frac{\beta}{n^2} \) is large. Using the function Eq. (23) constructed above, we have
\[
\begin{align*}
  f_R \left( \frac{\alpha}{n} \right) &= \exp \left[ \frac{\alpha}{n} (A + B) + \beta \frac{1}{n} [A, B] + O \left( \frac{\alpha \beta}{n^2} \right) \right. \\
  & \quad + \cdots + O \left( \frac{\beta^3}{n^7} \right) + \cdots \right]. \quad (25)
\end{align*}
\]

Repeating this function \( n \) time gives the desired gate:
\[
\begin{align*}
  f_{n/2} \left( \frac{\alpha}{n} \right)^n &= \exp \left[ \alpha (A + B) + \beta [A, B] \right. \\
  & \quad + O \left( \frac{\alpha \beta + \beta^2}{n} \right) \right]. \quad (26)
\end{align*}
\]

This implementation uses \( 6n \) gates and achieves error \( O \left( \frac{1}{n} \right) \).

In the limit \( \alpha \to 0, \beta \) constant, and \( n \gg 1 \), Eq. (25) converges to
\[
\begin{align*}
  \exp((g - 1)\sqrt{\frac{\beta}{n}} A) & \exp((g - 1)\sqrt{\frac{\beta}{n}} B) \exp(-\sqrt{\frac{\beta}{n}} A) \\
  \cdot \exp(-g \sqrt{\frac{\beta}{n}} B) & \exp((2 - g)\sqrt{\frac{\beta}{n}} A) \exp(\sqrt{\frac{\beta}{n}} B) \\
  = \exp \left( \frac{\beta}{n} [A, B] + O \left( \frac{\beta^2}{n^2} \right) \right). \quad (27)
\end{align*}
\]

where \( g = \frac{\sqrt{2} + 1}{2} \), which reduces to the pure commutator formula in Sec. II A. Notice that the error has the same order with or without the sum \( A + B \), which means that there is no extra cost to simulate the sum along with the commutator.

In Sec. V, we use Eq. (26) to generate new Hamiltonian terms from existing ones, such as next-nearest-neighbor (NNN) hopping terms from nearest-neighbor (NN) hopping terms. There is another useful formula that can easily be derived from Eq. (25):
\[
\exp \left( \frac{\alpha}{n} C \right) f_R \left( \frac{\alpha}{n} \right) \exp \left( \frac{\alpha}{n} (A + B + C) + \beta \frac{1}{n} [A, B] + O \left( \frac{1}{n^2} \right) \right), \quad (28)
\]
or equivalently,
\[
\left( \exp \left( \frac{\alpha}{n} C \right) f_R \left( \frac{\alpha}{n} \right) \right)^n = \exp \left( \alpha (A + B + C) + \beta [A, B] + O \left( \frac{1}{n} \right) \right), \quad (29)
\]

which uses \( 7n \) gates and has error \( O(1/n) \).

### III. RECURSIVE FORMULAS

In this section, we introduce the recursive construction of higher-order product formulas. We first focus on the pure commutator formula, where we improve over previous procedures [14, 15]. Then we discuss recursive formulas for both sum and commutator, following the same strategy as the recursive formula for the sum alone [13, 22, 23].

#### A. Pure commutator

In this section, we introduce recursive formulas that use 4, 5, 6, or 10 copies of an \( n \)-th-order formula to generate an \( (n + 2) \)-nd-order formula. To begin, assume we have an \( n \)-th-order formula for the commutator, of the form
\[
f_n(x) = \exp(x^2 [A, B]) + C_n x^{n+1} + D_n x^{n+2} + O(x^{n+3}) \quad (30)
\]
for some coefficients \( C_n, D_n \in R \). As in previous recursive constructions, we make essential use of inverse product formulas. Given an \( n \)-th-order product formula \( f_n(x) \), its inverse...
formula is \( f_n(x)^{-1} \) where

\[
f_n(x)^{-1} f_n(x) = 1. \tag{31}
\]

Since \( f_n(x) \) is a product of elementary exponentials

\[
f_n(x) = e^{p_1x}e^{p_2x}e^{p_3x} \ldots e^{p_kx},\]

its inverse is simply

\[
f_n(x)^{-1} = \left(e^{p_1x}e^{p_2x}e^{p_3x} \ldots e^{p_kx}\right)^{-1} = e^{-p_kx} \ldots e^{-p_3x}e^{-p_2x}e^{-p_1x}. \tag{33}
\]

Notice that we include coefficients \( C_n \) and \( D_n \) to keep track of the \( x^{n+1} \) and \( x^{n+2} \) terms, respectively. From \( f_n(x) \), we can construct other product formulas:

\[
f_n^{-1}(x) = \exp(-x^2[A,B]) - C_n x^{n+1} - D_n x^{n+2},
\]

\[
f_n(-x) = \exp(x^2[A,B]) - (-1)^n C_n x^{n+1}
\]

\[
+ (-1)^n D_n x^{n+2},
\]

\[
f_n^{-1}(-x) = \exp(-x^2[A,B]) + (-1)^n C_n x^{n+1}
\]

\[
- (-1)^n D_n x^{n+2},
\]

where we omit the \( O(x^{n+3}) \) error term for brevity. We use \( f_n(x) \) and Eq. (34) as building blocks for higher-order product formulas.

In particular, if \( n = 2k \) is even, there is a recursive formula that increases the order of the product formula by 1 using only 2 copies of the product formula \( f_n \) [15, Corollary 3]:

\[
f_{2k+1}(x) := f_{2k} \left( \frac{x}{\sqrt{2}} \right) f_{2k} \left( -\frac{x}{\sqrt{2}} \right) \tag{35}
\]

For general \( n \), there are two previously established ways to increase the order by 1:

1. The Jean-Koseleff formula [14]:

\[
f_{n+1}(x) = \exp(x^2[A,B] + O(x^{n+2}))
\]

\[
= \begin{cases} f_n(tx) f_n(sx) f_n(tx) & \text{if } n \text{ is even} \\ f_n(ux) f_n(ux)^{-1} f_n(ux) & \text{if } n \text{ is odd} \end{cases} \tag{36}
\]

with \( t = (2 + 2^{2/(n+1)})^{-1/2}, s = -2^{1/(n+1)}t, u = (2 - 2^{2/(n+1)})^{-1/2}, \) and \( v = 2^{1/(n+1)}u \).

2. The Childs-Wiebe (5-copy) formula [15]:

\[
f_{n+1}(x) = \exp(x^2[A,B] + O(x^{n+2}))
\]

\[
= f_n(\nu x)^2 f_n(\mu x)^{-1} f_n(\nu x)^2 \tag{37}
\]

with \( \mu = (4s_n)^{1/2}, \nu = (1/4 + \sigma)^{1/2}, \) and \( \sigma = \frac{4^{\frac{1}{4}}}{4(4-4^{1/4})} \).

1. \( \sqrt{6} \)-copy recursive formula

Theorem 2 of Ref. [15] defines a \( \sqrt{6} \)-copy recursive construction that improves the order of an even-order product formula \( f_{2k}(x) \) by 2 using 6 copies of \( f_{2k}(x) \) and \( f_{2k}(x)^{-1} \). We observe that this construction first applies the 2-copy formula Eq. (35) and then applies the Jean-Koseleff formula Eq. (36). Alternatively, we can consider these two steps independently and combine them in different ways. In particular, given an odd-order product formula, we can first apply the the Jean-Koseleff formula and then apply the 2-copy formula.

Here we explicitly describe this alternative \( \sqrt{6} \)-copy recursion for odd-order product formulas. Let \( V_n(x) \) be a product formula that approximates \( \exp(x^2[A,B]) \) with error \( O(x^{n+1}) \) for odd \( n \).

The two-step recursive relation has the form

\[
V_{n+2}(x) = V_n \left( \frac{ux}{\sqrt{2}} \right) V_n \left( \frac{ux}{\sqrt{2}} \right)^{-1} \times V_n \left( \frac{-ux}{\sqrt{2}} \right) V_n \left( \frac{-ux}{\sqrt{2}} \right)^{-1} \tag{38}
\]

where \( u = (2 - 2^{2/(n+1)})^{-1/2} \) and \( v = 2^{1/(n+1)}u \). Here the first three terms and the last three terms are \((n+1)\)-st-order formulas, which combine to give an \((n+2)\)-nd-order formula. This construction increases the order by 2 using 6 copies of \( V_n \) and \( V_n^{-1} \), so we call it a \( \sqrt{6} \)-copy recursion.

This approach can applied to our 3rd-order formula \( S_3(x) \) to get higher-order formulas. Letting \( N_n^V \) denote the number of gates in the \( n \)-th-order formula, we have

\[
N_{n+1}^V = \begin{cases} \frac{3}{2}N_n^V - 2 & \text{if } n \text{ is odd} \\ 2N_n^V & \text{if } n \text{ is even} \end{cases} \tag{39}
\]

Starting from \( N_3 = 6 \), this gives

\[
N_{2k+1}^V = \frac{1}{15}(13 \cdot 6^k + 12). \tag{40}
\]

2. \( \sqrt{10} \)-copy recursive formula

Let \( G_n(x) \) be an invertible product formula that approximates \( \exp(x^2[A,B]) \) with error \( O(x^{n+1}) \). If \( n \) is odd, the Childs-Wiebe (5-copy) formula, Eq. (37), can be used to increase its order by 1. If \( n \) is even, we can apply Eq. (35) to increase the order by 1 using 2 copies of \( G_n \). Overall, we use 10 copies of \( G_n \) and \( G_n^{-1} \) to increase the order by 2. Therefore, \( G_n(x) \) is a \( \sqrt{10} \)-copy product formula.

Let \( N_n^G \) denote the number of gates in the \( n \)-th-order formula. For odd \( n = 2k+1 \), we have

\[
N_{2k+2}^G = 5N_{2k+1}^G - 2; \tag{41}
\]

and for even \( n = 2k \), we have

\[
N_{2k+2}^G = 2N_{2k}^G. \tag{42}
\]
Combining Eqs. (41) and (42), we have

\[ N_{2k+3}^G = 10N_{2k+1}^G - 4. \quad (43) \]

Starting from the base formula with \( N_3 = 6 \), we have

\[ N_{2k+1}^G = \frac{1}{9}(5 \cdot 10^k + 4). \quad (44) \]

3. \( \sqrt[3]{5} \)-copy recursive formula

We now consider the product

\[ W_n(-s' x)W_n^{-1}(x) = \exp((s^2 + 2s x^2 - 2)x A, B) \]

\[ + (s^{n+1} + 2s^n + 1 - 2^C_n x^{n+1} \]

\[ + (s^{n+2} - 2s^n)D_n x^{n+2} + O(x^{n+3}). \quad (45) \]

We first choose \( s' = 2\sqrt[3]{\frac{1}{5}} \) such that \( s^{n+2} - 2s^n = 0 \). To eliminate the coefficient \( (s^{n+1} + 2s^n + 1 - 2^C_n x^{n+1} \), we have

\[ s^{n+1} + 2s^n + 1 = \left(1 + 2\sqrt[3]{\frac{1}{5}}\right)s^{n+1} = 2. \]

Therefore, we choose

\[ s = \frac{2}{1 + 2\sqrt[3]{\frac{1}{5}}} \]

Then we define a new variable

\[ x' := x\sqrt{(s^2 + 2s x^2 - 2)} \]

\[ = x\sqrt{\frac{2}{1 + 2\sqrt[3]{\frac{1}{5}}} + (1 + 2\sqrt[3]{\frac{1}{5}}) - 2} \]

\[ =: \alpha x. \quad (46) \]

We can check that \( r > 0 \) for \( n > 1 \). Finally, we get the \( (n + 2) \)nd-order formula

\[ W_{n+2}(x') \]

\[ = W_n(-s' x')W_n^{-1}(\frac{x'}{\alpha})W_n(s' x')W_n^{-1}(\frac{x'}{\alpha})W_n(-s' x'). \]

Letting \( N_n^W \) denote the number of gates in \( W_n \), we have the recursive relation

\[ N_{n+2}^W = 5N_n^W - 4. \quad (48) \]

With \( N_3 = 6 \), we have

\[ N_{2k+1}^W = 5^k + 1. \quad (49) \]

4. \( \sqrt[4]{4} \)-copy recursive formula

We now discuss a way to use only 4 copies of an \( n \)th-order product formula to generate an \( (n + 2) \)nd-order product formula. Let \( Q_n(x) \) be an invertible product formula that approximates \( \exp(xA, B) \) with error \( O(x^{n+1}) \). Consider the following product:

\[ Q_n(ax)Q_n^{-1}(bx)Q_n(cx)Q_n^{-1}(dx) \]

\[ = \exp((a^2 - b^2 + c^2 - d^2)x^2[A, B]) \]

\[ + (a^{n+1} - b^{n+1} + c^{n+1} - d^{n+1})C_n x^{n+1} \]

\[ + (a^{n+2} - b^{n+2} + c^{n+2} - d^{n+2})D_n x^{n+2} + O(x^{n+3}). \quad (50) \]

To produce a formula of order \( n + 2 \), we want to find \( a, b, c, d \) satifying

\[ a^{n+1} - b^{n+1} + c^{n+1} - d^{n+1} = 0 \]

\[ a^{n+2} - b^{n+2} + c^{n+2} - d^{n+2} = 0 \]

\[ a^2 - b^2 + c^2 - d^2 \neq 0. \quad (51) \]

If a solution exists, we can define a new variable \( x' = sx \), with \( s := \sqrt[a^2 - b^2 + c^2 - d^2]{a^2 - b^2 + c^2 - d^2} \), to find the \( (n + 2) \)nd-order formula

\[ Q_n(\frac{a}{s} x')Q_n^{-1}(\frac{b}{s} x')Q_n(\frac{c}{s} x')Q_n^{-1}(\frac{d}{s} x') \]

\[ = \begin{cases} 
Q_n(x') & \text{if } a^2 - b^2 + c^2 - d^2 > 0 \quad (52) \\
Q_n^{-1}(x') & \text{if } a^2 - b^2 + c^2 - d^2 < 0
\end{cases} \]

Let \( N_n^Q \) be the number of gates of the \( n \)th-order formula. The number of gates in such a formula satisfies

\[ N_{2k+3}^Q = 4N_{2k+1}^Q - 3. \quad (53) \]

With \( N_3 = 6 \), we have

\[ N_{2k+1}^Q = 5 \cdot 4^{k-1} + 1. \quad (54) \]

We can take \( a = 1, b = 2, \) and numerically solve Eq. (51) to find \( c \) and \( d \). Table III presents numerical solutions for \( n = 3, 5, 7, 9, 11 \). We prove in Appendix B that a solution exists for general \( n \).

B. Sum and commutator

We also construct a recursive formula for the product formula Eq. (25) for a linear combination of a sum and a commutator, using the same idea as the \( \sqrt{6} \)-copy approach described above. Suppose we have an \( m \)th-order product formula of the form

\[ f_{R,m}(x) = \exp(x(A + B) + \frac{x^2}{\alpha}[A, B]) + C_m x^{m+1} \]

\[ + O(x^{m+2}). \quad (55) \]

In this formula, the commutator term scales with \( x \) instead of \( x^2 \). While the commutator term is \( x^2R[A, B] \) in Eq. (23), it becomes \( \frac{x^2}{\alpha}[A, B] \) with the choice of large \( R = \frac{1}{\alpha} \). Since \( A + B \) and \( [A, B] \) are both first-order terms, the recursive formula for sum and commutator should be similar to the recursive formula for sum. Here we use Suzuki’s method [23] to construct the recursive product formula for sum and commutator.
If $m$ is even, then we consider the 3-copy sequence
\[
f_R,m(ax)f_R,m(bx)f_R,m(ax)
= \exp\left((2a-b)x(A+B)+(2a-b)\frac{x^\beta}{\alpha}[A,B]\right)
+ (2a^{m+1}-b^{m+1})C_m x^{m+1} + O(x^{n+2}).
\] (56)

To obtain an $(m+1)$st-order product formula, $a, b$ should satisfy
\[
2a-b = 1, \quad 2a^{m+1}-b^{m+1} = 0
\] (57)
to eliminate the $(2a^{m+1}-b^{m+1})C_m x^{m+1}$ term. The solution is
\[
a = (2-2^{1/(m+1)})^{-1}, \quad b = 2^{1/(m+1)} a.
\] (58)

If $m$ is odd, then we consider the 2-copy sequence
\[
f_R,m(-ax)^{-1}f_R,m(bx)
= \exp\left((a+b)x(A+B)+(a+b)\frac{x\beta}{\alpha}[A,B]\right)
+ (-a^{m+1}+b^{m+1})C_m x^{m+1} + O(x^{n+2}).
\] (59)

To eliminate the $C_m x^{m+1}$ term, we must have
\[
a + b = 1, \quad -a^{m+1}+b^{m+1} = 0,
\] (60)
which is satisfied with
\[
a = b = \frac{1}{2}.
\] (61)

IV. NUMERICAL EVIDENCE

The analytical formulas presented above indicate how the errors scale with powers of $x$. However, the constant factors in the error terms of different product formulas significantly affect their performance in practice. To better understand this, we numerically compare the different approaches. Specifically, we evaluate the performance of our $\sqrt{10}$-copy, $\sqrt{6}$-copy, $\sqrt{5}$-copy, and $\sqrt{4}$-copy recursive formulas built from the base formula $S_3(x)$, and compare them with the previous best method, the Childs-Wiebe $\sqrt{6}$-copy formula [15] (which is built from the base formula $S_2(x)$).

We evaluate the commutator product formulas with $A = -i\sigma_z$ and $B = -i\sigma_z$ for $x \in [10^{-2}, 10^{-1}]$. Fig. 3 plots the error compared to the exact exponential of the commutator $[A, B]$. The errors scale as $x^{6.001}$ ($G_5$), $x^{5.958}$ ($V_5$), $x^{5.867}$ ($W_5$), $x^{6.371}$ ($Q_5$), and $x^{4.920}$ ($\bar{V}_4$), in good agreement with the analytical scalings.

Next, we compare the number of gates required to achieve a fixed accuracy for different recursive formulas.

We set $e^{-i\sigma_z x}$ and $e^{-i\sigma_z x}$ as our elementary exponentials and $\exp([-i\sigma_z x, -i\sigma_z x])$ as our target. We numerically determine the minimum number of elementary exponentials (i.e., gates) to achieve a fixed accuracy $\|f(x) - \exp([-i\sigma_z x, -i\sigma_z x])\|_2 = 10^{-4}$ for different approximation formulas $f(x)$.

We calculate the number of gates to achieve error at most $10^{-4}$ using the aforementioned product formulas. Specifically, we consider $5^\text{th}$-order product formulas obtained from the base formula $S_3$ using the $\sqrt{4}$-copy ($Q_5$), $\sqrt{5}$-copy ($W_5$), $\sqrt{6}$-copy ($V_5$), and $\sqrt{10}$-copy ($G_5$) approaches. We compare them with the $4^\text{th}$-order formula $V_4$ obtained from the base formula $S_2$ using the Childs-Wiebe $\sqrt{6}$-copy recursion [15]. See Fig. 4 for the numerical comparison. The number of gates for the $\sqrt{10}$-copy formula $G_5$ is constant in the interval $x \in [0.1, 0.3]$ since its error is always below the threshold. Asymptotically, the scaling of the number of gates for an $n^\text{th}$-order formula to achieve fixed accuracy is $O(x^{2\frac{n+1}{2}})$. Fig. 4 numerically shows that the $\sqrt{10}$-copy formula has the best performance. Although the $\sqrt{4}$-copy, $\sqrt{5}$-copy, $\sqrt{6}$-copy, and $\sqrt{10}$-copy

| $n$ | $a$ | $b$ | $c$ | $d$ |
|-----|-----|-----|-----|-----|
| 3   | 1   | 1   | 1.982590733 | -0.8190972888 |
| 5   | 1   | 2   | 1.99650166 | -0.8642318466 |
| 7   | 1   | 1   | 1.999411381 | -0.8911860667 |
| 9   | 1   | 1   | 1.999880034 | -0.9091844711 |
| 11  | 1   | 1   | 1.999974677 | -0.9220693131 |

| $a^2 - b^2 + c^2 - d^2$ | 0.2597447625 | 0.2409130177 | 0.203432678 | 0.1729037481 | 0.1496868917 |
formulas all have the same error scaling, the constant factors determine their performance in practice.

Fig. 5 shows the error in simulating \( \exp([-i\sigma_x, -i\sigma_z]) \) using \( V_4 \) (the best previous method), \( Q_5 \), \( W_5 \), \( V_5 \), and \( G_5 \). The horizontal axis indicates the total number of elementary exponentials, while the vertical axis indicates the simulation error \( \| f(1/\sqrt{T})^r - \exp([-i\sigma_x, -i\sigma_z]) \|_2 \), where \( r \) is the number of time steps used in the simulation and \( f(x) \) is the product formula. In an \( r \)-step simulation, the total number of elementary exponentials for \( Q_5 \), \( W_5 \), \( V_5 \), \( G_5 \), and \( V_4 \) are 21\( r \), 26\( r \), 32\( r \), 56\( r \), and 22\( r \), respectively. The numerical results show that the larger number of exponentials in each time step of \( V_5 \) and \( G_5 \) is offset by their reduced error.

Fig. 4 and Fig. 5 show that \( V_5 \) and \( G_5 \) improve upon the best previous result \( V_4 \). Hybrid approaches that combine previous recursive formulas with our new base formula \( S_3(x) \) also give improvements over \( V_4 \), but they do not perform as well as \( W_5 \), \( V_5 \), and \( G_5 \), so we do not include them in Fig. 4 and Fig. 5.

V. APPLICATIONS TO QUANTUM SIMULATION

A. Counterdiabatic driving

In this section, we discuss using commutator product formulas to implement counterdiabatic driving (CD) [18–20, 24]. In an adiabatic process \( \mathcal{H}(\lambda(t)) \), the time evolution \( \exp(-i \int_0^T dt \mathcal{H}(\lambda(t))) \) keeps the system in its instantaneous ground state if \( \lambda(t) \) is slowing varying. In other words,

\[
|\Psi(\tau)\rangle \approx \exp\left(-i \int_0^\tau dt \mathcal{H}(\lambda(t))\right)|\Psi(0)\rangle,
\]

where \( |\Psi(\tau)\rangle \) denotes the ground state of \( \mathcal{H}(\lambda(t)) \). In general, this approximation fails if \( \lambda(t) \) varies too rapidly. However, by introducing counterdiabatic driving terms, the system can remain in the ground state even though \( \lambda(t) \) varies rapidly. Specifically,

\[
|\Psi(\tau)\rangle \approx \exp\left(-i \int_0^\tau dt \mathcal{H}_{\text{CD}}(\lambda(t))\right)|\Psi(0)\rangle
\]

where \([21, 24]\)

\[
\mathcal{H}_{\text{CD}}(\lambda(t)) = \mathcal{H}(\lambda(t)) + \dot{\lambda} C_\lambda
\]

with \( \langle m|C_\lambda|n\rangle = -i \frac{\langle m|\partial_\lambda H |n\rangle}{\epsilon_m - \epsilon_n} \), where \( |n\rangle \) denotes an eigenstate of \( \mathcal{H}(\lambda) \) with energy \( \epsilon_n \), i.e., \( \mathcal{H}(\lambda)|n\rangle = \epsilon_n|n\rangle \).

Ref. [21] proposes using Floquet engineering to generate the CD term \( C_\lambda \). This term can be expressed as the sum of nested commutators [21]

\[
C_\lambda = i \sum_k c_k(\lambda) \left[ H, \left[ H, \ldots [H, \partial_\lambda H] \right] \right],
\]

where the coefficients \( c_k(\lambda) \) are determined by minimizing the action

\[
S_1 = \text{Tr}[G_1^2]
\]

with

\[
G_1 = \partial_\lambda \mathcal{H} - i[H, C_\lambda].
\]

For simplicity, we truncate to only the first term, giving

\[
C_\lambda \approx ic_1(\lambda)[\mathcal{H}, \partial_\lambda \mathcal{H}].
\]

Commutator product formulas can be used to implement the CD term. To demonstrate this application, we consider the case \( \mathcal{H}(\lambda) = H_0 + \lambda H_1 \). The time evolution is

\[
\exp(-i \int_0^T dt \mathcal{H}_{\text{CD}}(t))
\]

\[
= \exp\left(- \int_0^T dt \left( i\mathcal{H}_0 + i\lambda \mathcal{H}_1 - \dot{\lambda} c_1(\lambda)[\mathcal{H}_0, \mathcal{H}_1] \right)\right).
\]

For each infinitesimal time interval \([t, t + \delta t]\), we apply the following unitary operator:

\[
\exp(-i\mathcal{H}_0\delta t - i\lambda \mathcal{H}_1\delta t + \dot{\lambda} c_1(\lambda)[\mathcal{H}_0, \mathcal{H}_1]\delta t).
\]
This unitary operator can be simulated by the product formula Eq. (25) with $A = -i\mathcal{H}_A$, $B = -i\mathcal{H}_B$, $n = \frac{\lambda}{2\pi}$, $\alpha = 1$, and $\beta = \frac{\lambda e(\lambda)}{\lambda}$. The product-formula error is $O((\beta + \beta^2)\delta t)$.

As a concrete example, consider using the product formula to simulate the counterdiabatic time evolution of the time-dependent two-qubit Hamiltonian $\mathcal{H}(\lambda) = \mathcal{H}_A + \mathcal{H}_B$ where

$$\mathcal{H}_A := h_z(\lambda - 1)(\sigma^+_1 + \sigma^+_2)$$
$$\mathcal{H}_B := J(\sigma^-_1 \sigma^+_2 + \sigma^-_2 \sigma^+_1)$$

with $\lambda(t) = \sin^2(\frac{\pi}{2}\sin^2(\frac{\pi}{2}t))$. Notice that $\mathcal{H}_A$ and $\mathcal{H}_B$ do not commute. The first-order counterdiabatic driving term is [21]

$$C_\lambda = -\frac{J h_z}{2} \frac{(\sigma^+_1 \sigma^-_2 + \sigma^+_2 \sigma^-_1)}{J^2 + 4(\lambda - 1)^2 h_z^2}. \tag{72}$$

We can write Eq. (72) as a commutator between $\mathcal{H}_A$ and $\mathcal{H}_B$:

$$C_\lambda = i\frac{1}{4(1-\lambda)} \left[-i\mathcal{H}_A, -i\mathcal{H}_B\right]. \tag{73}$$

Hence we can construct the first-order counterdiabatic term using a commutator product formula. In the product formula setting, we choose $A = -i\mathcal{H}_A$, $B = -i\mathcal{H}_B$, $n = \frac{1}{\alpha}$, $\alpha = 1$, and $\beta = \frac{1}{4(1-\lambda)} \mathcal{J}^2 + 4(\lambda - 1)^2 \mathcal{H}_2^2$ to implement the counterdiabatic Hamiltonian over a time interval $\delta t$. Defining $R = \frac{\mathcal{B}_n}{\alpha^2}$, the product formula Eq. (25) gives

$$f_R(\delta t) = e^{p_1(R)A\delta t}\frac{e^{p_2(R)B\delta t}}{\mathcal{J}^2}e^{p_3(R)A\delta t}$$
$$= \exp\left(\mathcal{B}(A + B) + \beta\delta t[A, B] + O(\delta t^2)\right)$$
$$= \exp\left(-i(\mathcal{H}_A + \mathcal{H}_B)\delta t - i(\lambda C_\lambda)\delta t\right)$$
$$= \exp(-i\mathcal{H}_{\lambda\lambda\text{CD}}),$$

where $p_i(R)$ is the solution Eq. (19), which provides a good approximation provided $R$ is large (i.e., $\delta t$ is small).\(^3\) The overall counterdiabatic time evolution is the product of $f_R(\delta t)$ for each time interval, i.e.,

$$\exp(-i \int_0^\tau d\tau \mathcal{H}_{\lambda\lambda\text{CD}}(\lambda(t))) = \prod_{k=0}^{N-1} f_R(t_k)(\delta t), \tag{75}$$

where $t_k = \frac{k}{N}\tau$ and $\delta t = \frac{\tau}{N}$. Notice that in each term, the operator $A$ and the parameter $R$ depend on $t_k$.

For comparison, the time evolution of the original Hamiltonian can be simulated as

$$\exp(-i \int_0^\tau d\tau \mathcal{H}(\lambda(t))) = \prod_{k=0}^{N-1} (e^{-i\mathcal{H}_A(t_k)\delta t/3}e^{-i\mathcal{H}_B(t_k)\delta t/3}), \tag{76}$$

\(^3\) For arbitrary $R$, the solution $p_i(R)$ can be determined numerically using Eq. (18). However, here we choose $\delta t$ to be small so that the solution $p_i(R)$ has the convenient form of Eq. (19).
Fig. 6 shows a numerical computation of these quantities. We see that the product formula simulation of counterdiabatic evolution uses the commutator term to keep the system close to the ground state, while the corresponding evolution with standard Trotterization deviates from the ground state after \( t \approx 0.6 \tau \).

We also examine the performance of the standard Trotter method and our digital CD approach for different numbers of gates in Fig. 7. When the number of gates large, the digital CD protocol has higher fidelity than the standard Trotter protocol. The final fidelity is determined by the schedule \( \lambda(t) \). Moreover, we see that even with fewer gates, the first-order CD approach has higher fidelity than the standard Trotter method.

### B. 1d fermion chain with next-nearest-neighbor hopping terms

In this section, we discuss how to generate the time evolution of a 1d fermion chain with nearest-neighbor (NN) and next-nearest-neighbor (NNN) hopping terms using only two-site gates acting on neighboring sites on a fermionic digital quantum simulator.\(^4\)

Consider a 1d fermion chain with one complex fermion on each site \( j \). The fermion operators \( c_j, c_j^\dagger \) satisfy the canonical anticommutation relations
\[
\{ c_j, c_k \} = \delta_{jk}, \quad \{ c_j, c_k^\dagger \} = \{ c_j^\dagger, c_k \} = 0. \tag{79}
\]

We partition the hopping terms into two sets: those between sites \( 2j, 2j+1 \) and between sites \( 2j+1, 2j+2 \). More explicitly, we define
\[
H_0 := (c_j^\dagger c_j + c_{j+1}^\dagger c_{j+1} + \cdots + c_{L-2}^\dagger c_{L-1}) + \text{h.c.}
\]
\[
H_1 := (c_j^\dagger c_j + c_{j+1}^\dagger c_{j+1} + \cdots + c_{L-1} c_0) + \text{h.c.}, \tag{80}
\]

where we use periodic boundary conditions and assume that the total number of sites \( L \) is even. Notice that the terms in \( H_0 \) pairwise commute, so the time evolution of \( H_0 \) is exactly the product of the time evolutions of the individual terms, and similarly for \( H_1 \). By choosing \( A = iH_0 \), \( B = iH_1 \), \( \alpha = -tT \), and \( \beta = -t_2T \) in Eqs. (24) and (25), we have
\[
f_{\alpha \beta}(\frac{\alpha}{n}) = \exp \left( -iH_{\text{eff}} \frac{T}{n} + O \left( \frac{LT^2}{n^2} \right) \right) \tag{81}
\]

where
\[
H_{\text{eff}} = t[H_0 + H_1] + it_2 [H_0, H_1]
\]
\[
= t \left( c_j^\dagger c_j + c_{j+1}^\dagger c_{j+1} + \cdots + \text{h.c.} \right)
\]
\[
+ t_2 \left( ic_j^\dagger c_j - ic_{j+1}^\dagger c_{j+1} + \cdots + \text{h.c.} \right). \tag{82}
\]

Repeating the product formula \( n \) times, we find
\[
f_{\alpha \beta}(\frac{\alpha}{n}) = \exp \left( -iH_{\text{eff}} T + O \left( \frac{LT^2}{n} \right) \right) \tag{83}
\]

The effective Hamiltonian \( H_{\text{eff}} \) is shown in Fig. 8. It contains NN hopping terms with amplitude \( t \) and NNN hopping terms with amplitude \( t_2 \) and alternating \( i \) and \(-i\) factors. Physically, this Hamiltonian corresponds to the insertion of a \( \frac{\pi}{2} \) flux in each triangle. If we transform the NNN term \( c_j^\dagger c_{j+2} \) to a qubit representation, it corresponds to a 3-qubit interaction \( \sigma_j^x \sigma_{j+1}^z \sigma_{j+2}^z \) as occurs in lattice gauge theories [25].\(^3\)

To simulate \( H_0 \) or \( H_1 \), we use \( \frac{L}{2} \) gates. To simulate the time evolution of \( H_{\text{eff}} \), we use \( 6n \times \frac{L}{2} = 3nL \) gates, which is proportional to the number of steps \( n \) and the chain length \( L \). Thus, using only nearest-neighbor terms (or 2-qubit gates in the qubit representation), we are able to simulate the next-nearest-neighbor terms (or 3-qubit gates) with the same number of gates as in standard Trotterization of a Hamiltonian with only nearest-neighbor terms.\(^5\) We do not require any gate decomposition of 3-qubit interactions.

### C. Fractional quantum Hall phases on lattices

In Ref. [27], Kapit-Mueller showed that the addition of an appropriate next-nearest-neighbor hopping terms to magnetic models on lattices can significantly flatten the lowest band. Such a band flattening can further stabilize and increase the gap of lattice quantum Hall states such as Laughlin states. In this section, we discuss how to simulate the Kapit-Mueller Hamiltonian with nearest-neighbor (NN) and next-nearest-neighbor (NNN) hopping terms on a two-dimensional square lattice using only the time evolution operators of nearest-neighbor hopping terms.

Using our product formula for both sum and commutator, as in Eq. (25), we can simulate the Hamiltonian of the Kapit-Mueller model. The general form of the Kapit-Mueller Hamiltonian can be regarded as a variation of the Hofstadter Hamiltonian [28], which involves not only NN hopping but also long-range hopping. The long-range hopping ensures a flat band, which can be regarded as a degenerate Landau levels to stabilize fractional quantum Hall states. By truncating to only the NN and NNN terms, the Kapit-Mueller model simplifies the interactions while still demonstrating features of fractional quantum Hall phases.

---

\(^4\) The following derivation uses fermionic operators \( c, c^\dagger \), which can be transformed to Pauli operators by the Jordan–Wigner transformation. Thus, this model can be realized by quantum computers with qubits using only two-qubit interactions.

\(^5\) In certain systems, there may be other ways of efficiently generating such a 3-qubit term. For example, in the Google quantum computer, this term can be realized using a few single-qubit and iSWAP gates [26]. In general, the best circuit depends on the details of the physical platform. The preceding discussion provides an alternative simulation method, which may benefit some quantum simulators.

\(^6\) In the standard Trotter approach, the evolution time for each step is the same and the effective Hamiltonian is the sum of the simulated terms. In the algorithm discussed here, the evolution times are fine-tuned such that the next-nearest-neighbor terms appear in the effective Hamiltonian.
FIG. 8. A 1d fermion chain with both nearest-neighbor (NN) and next-nearest-neighbor (NNN) hopping. The NN hopping terms are all $t$ while NNN terms are $it_2$ and $-it_2$ alternatively ($t, t_2$ are real). This corresponds to $\frac{\pi}{2}$ flux insertion in each triangle.

Specifically, the Kapit-Mueller Hamiltonian is of the form

$$H_{KM} = \sum_{\langle j,k \rangle} J(z_j, z_k) a_j^\dagger a_k,$$

where

$$J(z_j, z_k) = K(z) e^{i/2(z_j z_k^* - z_j^* z_k)} \phi$$

and

$$K(z) = t \times (-1)^{x+y+xy} e^{-\frac{\pi}{2}((1-\phi) |z|^2)}$$

with $z_j = x_j + iy_j$ denoting the position of the $j$th site, $z = z_k - z_j$ representing the displacement from the $j$th site to the $k$th site, and $\langle j,k \rangle$ indicating that $j, k$ are NN sites, and $\langle \langle j,k \rangle \rangle$ indicating that $j, k$ are NNN sites. The $a_j^\dagger$ operator is a bosonic creation operator acting on site $j$, and $\phi$ is the magnetic flux inside each plaquette, as shown in Fig. 9. The hopping phase factor $(z_j z_k^* - z_j^* z_k) \phi$ corresponds to a vector potential in the symmetric gauge.

For convenience, we use Cartesian coordinates $(m, n)$ to label lattice sites and rescale $\pi \phi$ to $\phi$. The lattice constant is set to 1. We divide all the nearest-neighbor hopping terms into four parts:

$$H_1 = -J \sum_{m+n \ even} e^{-i\phi} a_{m+1,n}^\dagger a_{m,n} + \text{h.c.},$$
$$H_2 = -J \sum_{m+n \ odd} e^{-i\phi} a_{m+1,n}^\dagger a_{m,n} + \text{h.c.},$$
$$H_3 = -J \sum_{m+n \ odd} a_{m,n+1}^\dagger a_{m,n} + \text{h.c.},$$
$$H_4 = -J \sum_{m+n \ even} a_{m,n+1}^\dagger a_{m,n} + \text{h.c.}$$

Using the bosonic commutation relation $[a_i, a_j^\dagger] = \delta_{i,j}$, we see that the commutator between two hopping terms that overlap on site $j$ is

$$-i[\{K_1 a_j^\dagger a_j + \text{h.c.}, K_2 a_j^\dagger a_k + \text{h.c.}\} = -iK_1 K_2 a_j^\dagger a_k + \text{h.c.}$$

Thus commutators between NN hopping terms can generate NNN hopping. We compute the following commutators between different NN hopping terms:

$$-i[H_1, H_3] = -J^2 \sum_{m+n = \ even} e^{-i(n+1)\phi} a_{m+1,n+1}^\dagger a_{m,n} + \text{h.c.} + J^2 \sum_{m+n = \ even} e^{-i(n+1)\phi} a_{m,n+1}^\dagger a_{m,n} + \text{h.c.},$$
$$-i[H_1, H_4] = -J^2 \sum_{m+n = \ even} e^{-i(n+1)\phi} a_{m+1,n+1}^\dagger a_{m,n} + \text{h.c.} + J^2 \sum_{m+n = \ even} e^{-i(n+1)\phi} a_{m,n+1}^\dagger a_{m,n} + \text{h.c.},$$
$$-i[H_2, H_3] = -J^2 \sum_{m+n = \ odd} e^{-i(n)\phi} a_{m+1,n+1}^\dagger a_{m,n} + \text{h.c.} + J^2 \sum_{m+n = \ odd} e^{-i(n)\phi} a_{m,n+1}^\dagger a_{m,n} + \text{h.c.},$$
$$-i[H_2, H_4] = -J^2 \sum_{m+n = \ odd} e^{-i(n)\phi} a_{m+1,n+1}^\dagger a_{m,n} + \text{h.c.} + J^2 \sum_{m+n = \ odd} e^{-i(n)\phi} a_{m,n+1}^\dagger a_{m,n} + \text{h.c.}$$

Therefore,

$$-i[H_1, H_3] - i[H_2, H_4] + i[H_1, H_4] + i[H_2, H_3]$$

$$= -2J^2 \sin\left(\frac{\phi}{2}\right) \sum_{m,n} e^{-i(n+\frac{1}{2})\phi} (a_{m+1,n+1}^\dagger a_{m,n} + a_{m+1,n}^\dagger a_{m,n+1}) + \text{h.c.},$$

Comparing the phase factors of NN hopping in Eq. (85) and NNN hopping in Eq. (87), we find the effective Hamiltonian
in terms of $H_1, H_2, H_3, H_4$ and their commutators,

$$H_{\text{eff}} = H_1 + H_2 + H_3 + H_4 - iJ'[H_1 - H_2, H_3 - H_4]$$

(89)

which describes a system with NN and NNN hopping where the magnetic flux inside each plaquette is $\phi/2$. Our product formula naturally generates the phase factor corresponding to a uniform magnetic field applied to the lattice. Since we can control the coefficient of the commutator term in the product formula, $H_{\text{eff}}$ is equivalent to Kapit-Mueller Hamiltonian with the choice $J' = \exp(\phi/4 - \pi/2)/(2\sin(\phi/2))$, which is fine tuned to realize a flat band. We can use our product formula Eq. (28) to simulate $H_{\text{eff}}$ by setting $A = i(H_1 - H_2), B = i(H_3 - H_4), C = i(2H_2 + 2H_4)$, and taking $\alpha = 1, \beta = J'$.

VI. DISCUSSION

We conclude by discussing some possible future research directions.

**Trajectories of product formulas:** Given a product formula

$$e^{p_1 x A} e^{p_2 x B} e^{p_3 x A} e^{p_4 x B} e^{p_5 x A} e^{p_6 x B} \ldots,$$

(90)

we can plot the “time evolution trajectory” of the coefficients of $A$ and $B$, namely $(p_1, p_1 + p_3, p_1 + p_3 + p_5, \ldots)$ and $(p_2, p_2 + p_4, p_2 + p_4 + p_6, \ldots)$, respectively. Ref. [13] studies product formulas for the sum $A + B$, with the time evolution trajectory starting from $t = 0$ and ending at $t = 1$. It suggests that a good formula product formula for the sum should have the entire time evolution trajectory inside the “allowed” interval $[0, 1]$, since times outside this interval do not correspond to the evolution under consideration.

For commutators, the time evolution trajectory starts and ends at $t = 0$, so we do not have an “allowed” interval. However, we can still plot the time evolution trajectories, as shown in Fig. 10 for the $\sqrt{4}$-copy and $\sqrt{10}$-copy product formulas. We see that $\sqrt{10}$-copy product formula has a smaller range for the time evolution trajectories of $A$ and $B$. This may explain why the $\sqrt{10}$-copy product formula performs better than the $\sqrt{4}$-copy product formula. Similar considerations hold for other formulas (for example, the ranges of the trajectories for the $\sqrt{5}$-copy formula are intermediate between those of the $\sqrt{4}$- and $\sqrt{10}$-copy formulas). It might be useful to develop a more general and quantitative understanding of how the trajectories of a product formula affect its performance.

**Optimal recursive relation:** We argue that the $\sqrt{4}$-copy recursive relation may use the smallest possible number of copies to generate higher-order product formulas. In other words, it seems unlikely that a recursive relation could use fewer than 2 copies of an $n$th-order product formula to generate an $(n + 1)$st-order product formula. To obtain a $p$th-order product formula, the coefficients of $p$th-order commutators must be eliminated. If $p$ is a prime, the number of independent commutators is $\frac{2p - 2}{p}$, which is the dimension of
the graded component of a free Lie algebra with length\(^7\) \(p\) [16, 17]. A \((2 - \epsilon)\)-copy recursive formula would use a number of exponentials proportional to \((2 - \epsilon)^p < \frac{2^p - 2}{p}\), which would mean using far fewer parameters than the number of polynomial equations to be solved. Thus we conjecture that there is no \((2 - \epsilon)\)-copy recursive formula.

**Direct derivation of a 4th-order commutator product formula:** To better understand possible direct constructions of commutator product formulas, we would like to solve the polynomial equations for the 4th-order case, namely

\[
e^{p_1 x A} e^{p_2 x B} e^{p_3 x A} e^{p_4 x B} e^{p_5 x A} e^{p_6 x B} \cdots = e^{x^2 [A, B]} + O(x^5).\]

(91)

We first revisit the polynomial equations Eq. (16) for the 3rd-order product formula. We can rewrite these equations as

\[
\mathcal{A} = 0, \quad \mathcal{B} = 0, \quad \mathcal{B} \mathcal{A} = -1, \quad \mathcal{A} \mathcal{B} \mathcal{A} = 0, \quad \mathcal{B} \mathcal{A} \mathcal{B} = 0,
\]

(92)

where

\[
\mathcal{A} := \sum_{i \text{ odd}} p_i = p_1 + p_3 + p_5 + \cdots
\]

(93)

represents the sum of all coefficients of the \(A\) term and

\[
\mathcal{B} := \sum_{i \text{ even}} p_i = p_2 + p_4 + p_6 + \cdots
\]

(94)

represents the sum of all coefficients of the \(B\) term. Then

\[
\mathcal{B} \mathcal{A} := \sum_{i \text{ even}, j \text{ odd}, i < j} p_i p_j,
\]

(95)

is the sum of all coefficients of the \(BA\) term, and similarly

\[
\mathcal{A} \mathcal{B} \mathcal{A} := \sum_{i \text{ odd}, j \text{ even}, k \text{ odd}, i < j < k} p_i p_j p_k,
\]

\[
\mathcal{B} \mathcal{A} \mathcal{B} := \sum_{i \text{ even}, j \text{ odd}, k \text{ even}, i < j < k} p_i p_j p_k.
\]

(96)

Following the same strategy, we can derive polynomial equations for the 4th-order commutator product formula:

\[
\mathcal{A} = 0, \quad \mathcal{B} = 0, \quad \mathcal{B} \mathcal{A} = -1, \quad \mathcal{A} \mathcal{B} \mathcal{A} = 0, \quad \mathcal{B} \mathcal{A} \mathcal{B} = 0, \quad \mathcal{A}^2 \mathcal{B} \mathcal{A} = 0, \quad \mathcal{B}^2 \mathcal{A} \mathcal{B} = 0, \quad \mathcal{A} \mathcal{B} \mathcal{A} - \mathcal{B} \mathcal{A} \mathcal{B} = 0,
\]

(97)

where we have defined

\[
\mathcal{A}^2 \mathcal{B} \mathcal{A} := \sum_{i \text{ odd}, j \text{ even}, k \text{ odd}, i < j} \frac{1}{2} p_i^2 p_j p_k + \sum_{i \text{ odd}, j \text{ even}, k \text{ even}, l \text{ odd}, i < j < k < l} p_i p_j p_k p_l,
\]

\[
\mathcal{B}^2 \mathcal{A} \mathcal{B} := \sum_{i \text{ even}, j \text{ odd}, k \text{ even}, i < j < k} \frac{1}{2} p_i^2 p_j p_k + \sum_{i \text{ even}, j \text{ odd}, k \text{ even}, l \text{ odd}, i < j < k < l} p_i p_j p_k p_l,
\]

\[
\mathcal{A} \mathcal{B} \mathcal{A} := \sum_{i \text{ even}, j \text{ odd}, k \text{ even}, i < j < k} p_i p_j p_k p_l,
\]

(98)

However, we do not have an analytical solution for these polynomial equations.

**Applications of counterdiabatic driving:** In Sec. VA, we gave a two-qubit example to demonstrate the potential effectiveness of counterdiabatic driving in digital quantum computers. We believe this approach can be used to prepare ground states of spin-chain systems with high fidelity. Looking beyond quantum simulation, there might exist other efficient quantum algorithms based on counterdiabatic driving.

**Appendix A: The operator differential method and commutator product formulas**

In this section, we introduce the operator differential method and show how it can be used to derive product formulas. We have [13]

\[
e^{p_1 x A} e^{p_2 x B} e^{p_3 x A} e^{p_4 x B} e^{p_5 x A} e^{p_6 x B} = e^{\Phi(x)}
\]

(A1)

with

\[
\Phi(x) = \sum_{k=0}^{\infty} \frac{(-1)^k}{k+1} \int_{0}^{x} (e^{p_1 t \delta A} e^{p_2 t \delta B} e^{p_3 t \delta A} e^{p_4 t \delta B} e^{p_5 t \delta A} e^{p_6 t \delta B} - 1)^k \times (p_1 A + e^{p_1 t \delta A} p_2 B + e^{p_1 t \delta A} e^{p_2 t \delta B} p_3 A \ldots) dt,
\]

(A2)

\(^7\)The length is the number of times \(A\) and \(B\) occur in Lie brackets. For example, there are two terms of length 3: \([A, [A, B]]\) and \([B, [B, A]]\).

\(^8\)While the number of terms in the product formula is finite, we do not indicate where it ends since we do not know a priori how many terms are required.
where $\delta_A O := [A, O]$ is called the operator differential. For example, the $x$ term in $\Phi(x)$ comes from integrating the constant term in Eq. (A2):

$$
\int_0^x (p_1A + p_2B + p_3A + p_4B + p_5A + p_6B) dt
= (IA + mB)x,
$$

where

$$
l := p_1 + p_3 + p_5,
m := p_2 + p_4 + p_6.
$$

Notice that only the $k = 0$ part contributes to the constant term in the integrand. The $x^2$ term in $\Phi(x)$ comes from the $t$ terms in the integrand, which have two contributions: from the $k = 0$ part,

$$
\frac{1}{2} \int_0^x dt \left[ p_1(p_2 + p_4 + p_6) + p_3(p_4 + p_6) + p_5 p_6 \right]\delta_A B
$$

and from the $k = 1$ part,

$$
\frac{1}{2} \int_0^x dt \left[ p_1(p_2 + p_4 + p_6) + p_3(p_4 + p_6) + p_5 p_6 
- p_2(p_3 + p_5) - p_4 p_5 \right]\delta_A B.
$$

The $x^2$ term is therefore

$$
x^2 \left( \frac{1}{2} (lm - 2q) \right) \delta_A B,
$$

where

$$
q := p_2 p_3 + p_2 p_5 + p_4 p_5.
$$

The $x^3$ term in $\Phi(x)$ has three contributions. The first comes from the $k = 0$ part:

$$
\frac{1}{2} \int_0^x \left[ \frac{t^2}{2} \left[ p_1^2(p_2 + p_4 + p_6) + p_3^2(p_4 + p_6) + p_5^2 p_6 
+ 2p_1p_3(p_4 + p_6) + 2(p_1 + p_3)p_5 p_6 
- 2p_1 p_2(p_3 + p_5) - 2(p_1 + p_3)p_4 p_5 \right] \delta_A B 
+ \frac{t^2}{2} \left[ p_2^2(p_3 + p_5) + p_3^2 p_5 + 2p_2 p_4 p_5 
- 2p_2 p_3(p_4 + p_6) - 2(p_2 + p_4)p_5 p_6 \right] \delta_B A \right] dt
$$

Defining

$$
l := p_1 p_2 p_3 + p_1 p_2 p_5 + p_1 p_4 p_5 + p_3 p_4 p_5,
rs := p_2 p_3 p_4 + p_2 p_3 p_6 + p_2 p_5 p_6 + p_4 p_5 p_6,
$$

the $k = 0$ part can be simplified as

$$
\frac{1}{6} \left[ \frac{t^2}{2} \left[ (lm - q)(lm - 3r)\delta_A^2 B + (mq - 3s)\delta_B^2 A \right] \right] dt
$$

Similarly, for $k = 1$ we have

$$
- \frac{1}{2} \int_0^x dt \left[ t(l\delta_A + m\delta_B)\left( (lm - 2q)\delta_A B \right) 
+ \frac{1}{2} t^2 \left( l^2 \delta_A^2 + m^2 \delta_B^2 + 2(lm - q)\delta_A \delta_B + 2q\delta_B \delta_A \right) \right] dt
$$

and for $k = 2$ we have

$$
\frac{1}{3} \int_0^x dt \left[ t^2(l\delta_A + m\delta_B)^2 (IA + mB) \right]
= \frac{1}{3} \int_0^x t^2 l_{A+mB} (IA + mB) = 0.
$$

Overall, the $x^3$ term is

$$
\frac{x^3}{6} \left[ \left( \frac{l^2 m}{2} - 3r \right) \delta_A^2 B + \left( \frac{m^2 l}{2} - 3s \right) \delta_B^2 A \right].
$$

1. Pure commutators

To give a pure commutator formula, we would like to find $(p_1, p_2, p_3, p_4, p_5, p_6)$ such that

$$
\Phi(x) = R[A, B]x^2 + O(x^4)
$$

for some constant $R$. For the first-order term to vanish, we require

$$
l = p_1 + p_3 + p_5 = 0,
m = p_2 + p_4 + p_6 = 0.
$$

The $x^2$ term, Eq. (A7), and $x^3$ term, Eq. (A14), contribute

$$
-x^2 q \delta_A B - \frac{x^3}{2} (r \delta_A^2 + s \delta_B^2) A.
$$

To eliminate the third-order term, we need to solve

$$
l = p_1 + p_3 + p_5 = 0,
m = p_2 + p_4 + p_6 = 0,
q = p_2 p_3 + p_2 p_5 + p_4 p_5 = -1,
r = p_1 p_2 p_3 + p_1 p_2 p_5 + p_1 p_4 p_5 + p_3 p_4 p_5 = 0,
s = p_2 p_3 p_4 + p_2 p_3 p_6 + p_2 p_5 p_6 + p_4 p_5 p_6 = 0.
$$

One can check that the following choice satisfies the equations:

$$
p_1 = \frac{\sqrt{5} - 1}{2}, p_2 = \frac{\sqrt{5} - 1}{2}, p_3 = -1,
p_4 = -\frac{\sqrt{5} + 1}{2}, p_5 = \frac{3 - \sqrt{5}}{2}, p_6 = 1.
$$

Thus we have the explicit product formula Eq. (14).
2. Sums and commutators

Now consider a case where we include both linear and commutator terms, namely

\[ \Phi(x) = (A + B)x + R[A, B]x^2 + O(x^4), \] (A20)

for an arbitrary constant \( R \). The first-order term requires

\[ l = p_1 + p_3 + p_5 = 1, \]
\[ m = p_2 + p_4 + p_6 = 1, \] (A21)

and the \( x^2 \) and \( x^3 \) terms are

\[ \frac{x^2}{2} (1 - 2q) + \frac{x^3}{6} \left[ \left( \frac{1}{2} - 3r \right) \delta_A B + \left( \frac{1}{2} - 3s \right) \delta_B A \right], \] (A22)

which agrees with the derivation in Ref. [13]. Therefore, the equations to be solved are

\[ l = p_1 + p_3 + p_5 = 1, \]
\[ m = p_2 + p_4 + p_6 = 1, \]
\[ q = p_2 p_3 + p_2 p_5 + p_4 p_5 = -R + \frac{1}{2}, \]
\[ r = p_1 p_2 p_3 + p_1 p_2 p_5 + p_1 p_4 p_5 + p_3 p_4 p_5 = \frac{1}{6}, \]
\[ s = p_2 p_3 p_4 + p_2 p_3 p_6 + p_2 p_5 p_6 + p_4 p_5 p_6 = \frac{1}{6}. \] (A23)

Appendix B: Existence of the \( \sqrt{4} \)-copy recursive formula

In this section, we prove that a real solution of

\[
\begin{align*}
    a^{n+1} - b^{n+1} + c^{n+1} - d^{n+1} &= 0 \\
    a^{n+2} - b^{n+2} + c^{n+2} - d^{n+2} &= 0 \\
    a^2 - b^2 + c^2 - d^2 &= 0
\end{align*}
\] (B1)

exists for any odd \( n = 2k - 1 \). We first take \( a = 1 \) and \( b = 2 \), giving

\[
\begin{align*}
    c^{2k} - d^{2k} &= 2^{2k} - 1, \\
    c^{2k+1} - d^{2k+1} &= 2^{2k+1} - 1. \tag{B2}
\end{align*}
\]

The solution \((c, d) = (2, 1)\) is trivial since \( a^2 - b^2 + c^2 - d^2 = 0 \). We show that there exists a solution of the form \((c, d) = (2 - \epsilon_2, -1 + \epsilon_1)\) with \( 1 \geq \epsilon_1, \epsilon_2 \geq 0 \).

For any positive integer \( k \), the solutions of Eqs. (B2) and (B3) line on curves in the \((\epsilon_1, \epsilon_2)\) plane. We can check that the solutions of Eq. (B2) include the two points \((\epsilon_1, \epsilon_2) = (0, 0)\) with \( y_1 := 2 - (2^{2k} - 1) \pi \). Similarly, the solutions of Eq. (B3) include \((\epsilon_1, \epsilon_2) = (0, 0)\) and \((1, y_3)\) with \( y_2 = 2 - (2^{2k+1} - 2) \pi \) and \( y_3 = 2 - (2^{2k+1} - 1) \pi \). Notice that \( y_1 < y_2 < y_3 \). As shown in Fig. 11, the curve for Eq. (B2) is monotonically increasing and the curve for Eq. (B3) is monotonically decreasing, so these curves must intersect in the region \( 0 < \epsilon_1 < 1 \), providing a simultaneous solution of the two equations.

The final step is to show \( a^2 - b^2 + c^2 - d^2 \neq 0 \), or equivalently,

\[ (2 - 2\epsilon_2)^2 - (1 - \epsilon_1)^2 \neq 3. \] (B4)

It suffices to show that

\[ (2 - 2\epsilon_2)^2 - (1 - \epsilon_1)^2 = 3 \] (B5)

and

\[ (2 - 2\epsilon_2)^{2k} - (1 - \epsilon_1)^{2k} = 2^{2k} - 1 \] (B6)

have no intersection in the interval \( 0 < \epsilon_1 < 1 \) for \( k > 1 \). For each equation, we can think of \( \epsilon_2 \) as a function of \( \epsilon_1 \), i.e.,

\[
\begin{align*}
    f_1(x) &= 2 - [3 + (1 - x)^2]^{\frac{1}{2}}, \\
    f_2(x) &= 2 - [2^{2k} - 1 + (1 - x)^{2k}]^{\frac{1}{2}},
\end{align*}
\] (B7)

corresponding to Eq. (B5) and Eq. (B6), respectively. Now consider their derivatives:

\[
\begin{align*}
    f_1'(x) &= \frac{1-x}{[3 + (1-x)^2]^{\frac{3}{2}}}, \\
    f_2'(x) &= \frac{(1-x)^{2k-1}}{[2^{2k} - 1 + (1-x)^{2k}]^{\frac{3}{2}}}.
\end{align*}
\] (B8)

For \( 0 < x < 1 \) and \( k > 1 \), we have \((1-x) > (1-x)^{2k-1}\) and \([3 + (1-x)^2]^{\frac{1}{2}} < [2^{2k} - 1 + (1-x)^{2k}]^{\frac{3}{2}}\), so \( f_1'(x) > f_2'(x) \). Starting from the initial point \( f_1(0) = f_2(0) = 0 \), \( f_1(x) \) and \( f_2(x) \) cannot intersect in the interval \( 0 < x < 1 \). Therefore \( a^2 - b^2 + c^2 - d^2 \neq 0 \) and the solution for Eq. (51) always exists.
