The Structure of Positive Decompositions of Exponential Operators

Siu A. Chin

Department of Physics, Texas A&M University, College Station, TX 77843, USA

The solution of many physical evolution equations can be expressed as an exponential of two or more operators acting on initial data. Accurate solutions can be systematically derived by decomposing the exponential in a product form. For time-reversible equations, such as the Hamilton or the Schrödinger equation, it is immaterial whether or not the decomposition coefficients are positive. In fact, most symplectic algorithms for solving classical dynamics contain some negative coefficients. For time-irreversible systems, such as the Fokker-Planck equation or the quantum statistical propagator, only positive-coefficient decompositions, which respect the time irreversibility of the diffusion kernel, can yield practical algorithms. These positive time steps only, forward decompositions, are a highly effective class of factorization algorithms. This work introduces a framework for understanding the structure of these algorithms. By a suitable representation of the factorization coefficients, we show that specific error terms and order conditions can be solved analytically. Using this framework, we can go beyond the Sheng-Suzuki theorem and derive a lower bound for the error coefficient $\epsilon_{VTV}$. By generalizing the framework perturbatively, we can further prove that it is not possible to have a sixth order forward algorithm by including only the commutator $[VT, V] \equiv [V, [V, T, V]]$. The pattern of these higher order forward algorithms is that in going from the $(2n)^{th}$ to the $(2n+2)^{th}$ order, one must include a new commutator $[VT^{2n-1}V]$ in the decomposition process.

I. INTRODUCTION

Many physical evolution equations, from classical mechanics, electromagnetic, statistical mechanics to quantum mechanics, all have the form

$$\frac{\partial w}{\partial t} = (T + V)w,$$

(1.1)

where $T$ and $V$ are non-commuting operators. Such an equation can be solved iteratively via

$$w(t + \epsilon) = e^{(T+V)}w(t),$$

(1.2)

provided that one has a suitable approximation for the short time evolution operator $e^{(T+V)}$. Usually, $e^{T}$ and $e^{V}$ can be solved exactly. By factorizing $e^{(T+V)}$ to higher order in the form

$$e^{(T+V)} = \prod_{i=1}^{N} e^{T\epsilon} e^{V\epsilon},$$

(1.3)

one can solve \[1\] accurately with excellent conservation properties. Classically, each factorization \[1\] produces a symplectic integrator which exactly conserve all Poincaré invariants. A vast literature \[2,3\] exists on producing symplectic integrators of the form \[1\]. Once a factorization scheme is derived, it can be implemented specifically to solve any particular evolution equation of the form \[1\].

However, as one examines these factorization schemes more closely, one is immediately struck by the fact that beyond second order, all such scheme contain some negative coefficients\[1,2,3\], $t_{i}$ and $v_{i}$. Since the fundamental diffusion kernel cannot be simulated or integrated backward in time, none of these higher order schemes can be applied to time-reversible systems. This lack of positive-coefficient decompositions beyond second order was first noted and proved by Sheng\[11\]. Sheng showed that equations for determining the third order coefficients in \[1\] are incompatible if the coefficients $\{t_{i}, v_{i}\}$ are assumed to be positive. This is a valuable demonstration, but it shed no light on the cause of this incompatibility nor offered clues on how to overcome this deficiency. Suzuki later proved that the incompatibility can be viewed more geometrically. His proof tracked the coefficients of the operator $TTV$ and $TVV$ in the product expansion of \[1\]. If the expansion were correct to third order, then the coefficients for both operators must be $1/3$! The coefficient condition for one corresponds to a hyperplane and the other, a hypersphere. Suzuki then went on to show that for the same set of positive coefficients, the hyperplane cannot intersect the hypersphere and therefore no real solution is possible.

The product form \[1\] has the general expansion

$$\prod_{i=1}^{N} e^{T\epsilon} e^{V\epsilon} = \exp \left( e_{T} \epsilon T + e_{V} \epsilon V + e_{TTV} \epsilon^{2} [T, V] + e_{TTV} \epsilon^{3} [T, V] + \cdots \right) = e^{\epsilon H_{A}(\epsilon)},$$

(1.4)

where the last equality defines the approximate Hamiltonian of the product decomposition. The goal of factorization is to keep $e_{T} = e_{V} = 1$ and forces all other error coefficients such as $e_{TTV}, e_{TTV}, e_{TTV}^{\epsilon}, e_{TTV}$, etc., to zero. By tracing the incompatibility condition to error coefficients of specific operators, one can identify which error term cannot be made to vanish. The operator $TTV$ can only occur in $[T, [T, V]]$ and $TTV$ only in $[V, [T, V]]$. Thus the incompatibility condition is equivalent to the fact that for positive coefficients $\{t_{i}, v_{i}\}$, the $TTV$ and $e_{TTV}$ cannot both be reduced to zero. To circumvent this, it is suffice to
force one error coefficient to zero and keep the other commutator in the factorization process. Since in quantum mechanics $[V, [T, V]]$ corresponds to a local function, just like the potential, Suzuki suggested that one should factorize $e^{\varepsilon(T+V)}$ in terms of $T$, $V$ and $[V, [T, V]]$. Following up on this suggestion, Suzuki and Chin have derived fourth order factorization algorithms with only positive coefficients. Chin also shown that classically, $[V, [T, V]]$ gives rise to a force gradient exactly as first suggested by Ruth.

In Suzuki’s proof, without explicitly computing $e^{\varepsilon(T+V)}$ and $e^{\varepsilon V T}$, he showed that both cannot be zero. Here, we show that by enforcing $e_{TV} = 0$ and $e_{TTV} = 0$, we can compute a lower bound for $e_{VT}$ analytically and show that it cannot vanish for a set of positive $\{t_i\}$. This determination of a lower bound for $e_{VT}$ goes beyond the Sheng-Suzuki theorem in providing a more detailed understanding of all fourth order forward algorithms.

The first step of our approach is to compute the error coefficients $e_{TV}$, $e_{TTV}$, $e_{VT}$, etc., in terms of the factorization coefficients $\{t_i, v_i\}$. This can be done as follow. The left hand side of (1.1) can be expanded as

\[
e^{\varepsilon t_i T} e^{\varepsilon v_i V} \ldots e^{\varepsilon n T} e^{\varepsilon v_N V} = 1 + \varepsilon \left( \sum_{i=1}^{N} t_i \right) T + \varepsilon \sum_{i=1}^{N} v_i V + \ldots \quad (2.1)
\]

Fixing $e_{T} = e_{V} = 1$, the right hand side of (1.1) can likewise be expanded

\[
e^{\varepsilon H_A(\varepsilon)} = 1 + \varepsilon (T + V) + \frac{1}{2} \varepsilon^2 (T + V)^2 + \varepsilon^2 e_{TV} [T, V] + e_{VT} e_{TV} [V, [T, V]] + \varepsilon^3 e_{TTV} [T, [T, V]] + \frac{1}{2} \varepsilon^3 e_{VT} \{(T + V)[T, V] + [T, V](T + V)\} + \frac{1}{3!} \varepsilon^3 (T + V)^3 + \ldots \quad (2.2)
\]

Matching the first order terms in $\varepsilon$ gives the primary constraints

\[
\sum_{i=1}^{N} t_i = 1 \quad \text{and} \quad \sum_{i=1}^{N} v_i = 1. \quad (2.3)
\]

To determine the other error coefficients, we focus on a particular operator in (2.2), whose coefficient contains $e_{TV}$, $e_{TTV}$ or $e_{VT}$ and match that operator’s coefficients in the expansion of (2.1). For example, in the $\varepsilon^2$ terms of (2.2), the coefficient of the operator $TV$ is $\left( \frac{1}{2} + e_{TV} \right)$. Equating this to the coefficients of $TV$ from (2.1) gives

\[
\frac{1}{2} + e_{TV} = \sum_{i=1}^{N} s_i v_i, \quad (2.4)
\]

where we have introduced the variable

\[
s_i = \sum_{j=1}^{i} t_j. \quad (2.5)
\]

Alternatively, the same coefficient can also be expressed as

\[
\frac{1}{2} + e_{VT} = \sum_{i=1}^{N} t_i u_i, \quad (2.6)
\]

where

\[
u_i = \sum_{j=i}^{N} v_j. \quad (2.7)
\]

II. A CONSTRUCTIVE PROOF OF THE SHENG-SUZUKI THEOREM

In Suzuki’s proof, without explicitly computing $e_{TTV}$ and $e_{VT}$, he showed that both cannot be zero. Here, we have used these forward factorization schemes in doing quantum statistical calculations and Omelyan et al. have produced an extensive collection of higher order algorithms based on this class of fourth order forward algorithms.

An important question therefore arises: with the inclusion of the operator $[V, [T, V]]$, can one produce forward algorithms of sixth or higher order? The answer provided by this work is “no”. For a sixth order decomposition with positive coefficients, the commutator $[V, [T, [T, V]]]$ cannot be made to vanish and must be included. In order to prove this result we have developed a formalism to analyze the structure of these forward factorization schemes. By use of a suitable representation of the factorization coefficients, we show that linear order conditions and quadratic error terms can both be solved analytically. The resulting error term then makes it obvious that it cannot vanish if the factorization coefficients are purely positive. By use of this formalism we can go beyond the Sheng-Suzuki theorem and derive a lower bound for the magnitude of the error coefficient $e_{VT}$.

By generalizing the method to sixth order, we further prove the main result as stated above. This analytical method of solving the order conditions will allow us to analyze and classify factorization algorithms in general.

In the next section we introduce our notations and illustrate our method of solving the order condition analytically by giving a constructive proof of the Sheng-Suzuki theorem. In Section III, we discuss the conditions necessary for a six order forward algorithm. In Section IV we introduce a perturbative approach to study the sixth order case and show that it is not possible to have a forward sixth order algorithm by including only the commutator $[V, [T, V]]$. In Section V we discuss the pattern of higher order forward algorithms. In Section VI, we summarize our conclusions and suggest directions for future research. The Appendix contains details of how to reduce a general quadratic error coefficient to a multi-diagonal form.
It turns out that $s_i$ and $u_i$ are our fundamental variables, the coefficients $t_i$ and $v_i$ are backward and forward finite differences of $s_i$ and $u_i$,

$$
t_i = s_i - s_{i-1} \equiv \nabla s_i,
$$

$$
v_i = u_i - u_{i+1} \equiv -\nabla u_i.
$$

The results (2.3) and (2.10) are equivalent by virtue of the “partial summation” identity

$$
\sum_{i=1}^{N} \nabla s_i u_i = - \sum_{i=1}^{N} s_i \Delta u_i.
$$

(Note that $s_0 = 0$ and $u_{N+1} = 0$.) In the following, we will use the backward finite difference operator extensively,

$$
\nabla s^n_i = s^n_i - s^n_{i-1},
$$

with property

$$
\sum_{i=1}^{N} \nabla s_i = s_N^n = 1.
$$

Matching the coefficients of operators $TTV$ and $TVV$ gives

$$
\frac{1}{3!} + \frac{1}{2} e_{TV} + e_{TTV} = \frac{1}{2} \sum_{i=1}^{N} s^n_i = \frac{1}{2} \sum_{i=1}^{N} \nabla s_i^2 u_i.
$$

$$
\frac{1}{3!} + \frac{1}{2} e_{TV} - e_{TTV} = \frac{1}{2} \sum_{i=1}^{N} \nabla s_i u_i^2.
$$

The error coefficient $e_{VTV}$ can be tracked directly by the operator $VTV$. The coefficient for the operator $VTV$ is quadratic in $v_i$ but not diagonal. This is more difficult to deal with than $TVV$’s coefficient. Nevertheless, we show in the Appendix that, $VTV$’s coefficient can be diagonalized by a systematic procedure to yield the same constraint equation as (2.12).

In order to have a fourth order algorithm, aside from the primary constraints (2.3), one must require $e_{TV} = 0$, $e_{TTV} = 0$, and $e_{VTV} = 0$. For a symmetric product form such that $t_1 = 0$ and $v_i = v_{N-i+1}$, $t_{i+1} = t_{N-i+1}$, or $v_N = 0$ and $v_i = v_{N-i}$, $t_i = t_{N-i+1}$, one has

$$
e^{-\frac{\varepsilon}{2} H_A(-\varepsilon)} \epsilon^{H_A(\varepsilon)} = 1.
$$

This implies that $H_A(\varepsilon)$ must be a even function of $\varepsilon$, and $e_{TV} = 0$ is automatic. The vanishing of all odd order errors in $H_A(\varepsilon)$ implies that we must have

$$
\frac{1}{(2n-1)!} \sum_{i=1}^{N} \nabla s_i^{2n-1} u_i = \left(\frac{1}{2n}\right)^n,
$$

ensuring that $T^{2n-1}V$ has the correct expansion coefficient. It is cumbersome to deal with symmetric coefficients directly, it is much easier to use the general form (2.13) and to invoke (2.14) when symmetric factorization is assumed.

The next step in our strategy is compute a lower bound for the magnitude of $e_{VTV}$, after satisfying constraints $e_{TV} = 0$ and $e_{TTV} = 0$. We view latter two constraints

$$
\sum_{i=1}^{N} \nabla s_i u_i = \frac{1}{2},
$$

$$
\sum_{i=1}^{N} \nabla s_i^2 u_i = \frac{1}{3},
$$

as constraints on $\{u_i\}$ for given a set of $\{t_i\}$ coefficients. For positive $\{t_i\}$, the RHS of (2.12) is a positive-definite quadratic form in $u_i$. Its lower bound can be determined by the method of constrained minimization using Lagrange multipliers. Minimizing

$$
F = \frac{1}{2} \sum_{i=1}^{N} \nabla s_i u_i^2 - \lambda_1 \left( \sum_{i=1}^{N} \nabla s_i u_i - \frac{1}{2} \right)
$$

$$
- \lambda_2 \left( \sum_{i=1}^{N} \nabla s_i^2 u_i - \frac{1}{3} \right)
$$

(2.17)

gives

$$
u_i = \lambda_1 \nabla s_i + \lambda_2 \nabla s_i^2 = \lambda_1 + \lambda_2(s_i + s_{i-1}).
$$

(2.18)

Imposing (2.15) and (2.16) determines $\lambda_1$ and $\lambda_2$,

$$
\lambda_1 + \lambda_2 = \frac{1}{2},
$$

(2.19)

$$
\lambda_1 + \lambda_2 + g \lambda_2 = \frac{1}{3},
$$

(2.20)

where $g$ defined by

$$
\sum_{i=1}^{N} \nabla s_i^3 = 1 + g,
$$

(2.21)

is given by

$$
g = \sum_{i=1}^{N} s_i s_{i-1}(s_i - s_{i-1}).
$$

(2.22)

By substituting in $s_i s_{i-1} = (s_i^2 + s_{i-1}^2) - (s_i - s_{i-1})^2)/2$, one discovers that

$$
g = -\frac{1}{2} g + \frac{1}{2}(1 - \delta g),
$$

and therefore

$$
g = \frac{1}{3}(1 - \delta g),
$$

where $\delta g = \sum_{i=1}^{N} \epsilon_i^3$.

(2.23)

The factor $1/3$ is the continuum limit ($N \to \infty$) of $g$ when the sum is replaced by the integral $\int_0^1 s^2 ds$. The
evaluation of general sums of the form \((2.22)\) will be further discuss below. This exact form for \(g\) obviated the need to determine \(g\)'s upper bound as it is done originally in the work of Suzuki\(^2\), and in the more recent work on symplectic correctors.\(^3\) With \(\lambda_1\) and \(\lambda_2\) known, the minimum of \(F\) is given by

\[
F = \frac{1}{2}(\lambda_1 + \lambda_2)^2 + \frac{1}{2}g\lambda_2^2 = \frac{1}{4} + \frac{g}{72g} = \frac{1}{6} + \frac{\delta g}{24(1 - \delta g)}. \quad (2.24)
\]

and therefore,

\[
e_{VTV} \leq \frac{1}{24}(1 - \delta g). \quad (2.25)
\]

This implies that, first, \(e_{VTV}\) must be negative. Secondly, its magnitude is

\[
|e_{VTV}| \geq \frac{1}{24}(1 - \delta g). \quad (2.26)
\]

The Sheng-Suzuki theorem now follows as a simple corollary. If all the \(t_i\)'s are positive, then \(e_{VTV}\) cannot vanish because its lower bound \((2.26)\), which depends on \(\delta g\) as given by \((2.26)\), cannot vanish. The only way to achieve a fourth order forward algorithm is to keep the commutator \([V, [T, V]]\) with coefficient \(e_{VTV}\), but move it to the left hand side of \((1.3)\). This means that for all such fourth order algorithms, the sum of factorization coefficients of all the \([V, [T, V]]\) terms must be positive. All such fourth order algorithms are characterized by their respective values of \(e_{VTV}\), and how well they saturate the lower bound \((2.26)\). Note that in deriving this lower bound, we did not need to incorporate the primary constraints \(u_i = 1\).

A very different “elementary” proof of the Sheng-Suzuki result has been offered by Blanes and Casa.\(^4\) Our work is more precise in demonstrating that, not only \(e_{VTV}\) cannot vanish, it has a lower bound \((2.26)\) determined only by \(t_i\).

Note also that \(v_i = u_i - u_{i+1}\) and \((2.18)\) implies that

\[
v_i = \lambda_2(s_i - s_{i+1}) = \frac{1}{2}(t_i + t_{i+1} - 1)(1 - \delta g). \quad (2.27)
\]

Thus, if one insists that \(e_{VTV}\) be zero, then \(\delta g\) can be zero only if at least one \(t_i\) is negative such that \((t_i + t_{i+1})\) or \((t_i + t_{i-1})\) remains negative. Eq.\((2.27)\) then implies that its adjacent values of \(v_i\) or \(v_{i-1}\) must also be negative. Thus a fourth order factorization without keeping any additional operator such as \([V, [T, V]]\) must have at least one pair of negative \(t_i, v_i\) coefficients. This result was first proved by Goldman and Kaper.\(^5\) This simpler proof follows the idea of Blanes and Casa.\(^4\)

### III. THE SIXTH ORDER CASE

By incorporating the potential-like operator \([V, [T, V]]\), many families of fourth order forward algorithms have been found. They are not only indispensable for solving time-irreversible problems;\(^6\) they are also superior to existing fourth order algorithms in solving time-reversible classical\(^7\) and quantum\(^8\) dynamical problems. It is therefore of great interest to determine whether there exist practical forward algorithms of even higher order. We show in this section that sixth order forward algorithms requires the inclusion of the commutator \([V, [T, [T, [T, V]]]]\). The inclusion of \([V, [T, V]]\) which make possible fourth order forward algorithms, is insufficient to guarantee a sixth order forward algorithm. In general, if \(F_{2n}(\varepsilon)\) is a 2\(n\)th order forward decomposition of \(e^{(T+V)}\), then \(F_{2n+2}(\varepsilon)\) would require the inclusion of a new operator not previously included in the construction of \(F_{2n}(\varepsilon)\). We have proved the case of \(n = 1\) in the last section. The new operator being

\[
V_1 \equiv [V, [T, V]]. \quad (3.1)
\]

Consider now the case \(n = 2\). In the following discussion, we will use the condensed bracket notation: \([V^2T^3V] = [V, [V, [V, [T, [T, V]]]]]\), etc.. We have shown in the last section that, for positive \(t_i\), with \(u_i\) satisfying constraints \((2.15)\) and \((2.16)\), we can factorize \(e^{(T+V)}\) up to the form

\[
\prod_{i=1}^{N} e^{i\varepsilon T}e^{v_i\varepsilon V} = \exp\left[\varepsilon\left(T + V + e_{VTV}\varepsilon^2[VTV]ight)
+\varepsilon^4\sum_{i=1}^{4} e_i Q_i + O(\varepsilon^6)\right], \quad (3.2)
\]

where \(e_{VTV}\) cannot be made to vanish, and \(Q_i\) are four independent operators described below. There is one error operator \([TV]\) in first order, two error operators \([TTV]\) and \([VTV]\) in second order, four operators \([TTTV]\, [VTTV]\, [TVTV]\) and \([VVTV]\) in third order, and eight operators

\[
[TTTTV], \ [VTTTV], \ [TVTTV], \ [VVTTV], \ [TTTV], \ [VTTV], \ [VVTV], \ [VVT] \ [VVTV]
\]

in fourth order. These error operators are results of concatenating \(T\) and \(V\) with lower order operators on the left. In each order, not all the operators are independent. For example, setting \(C = [AB]\) in the Jacobi identity

\[
[ABC] + [BCA] + [CAB] = 0,
\]

gives \([ABC] = [BAC]\) and therefore

\[
[ABAB] = [BAAB].
\]

For the case where \([VTV]\) commutes with \(V\) we also have \([V^nVTV] = 0\). Hence there are only two independent operators \([TTTV]\, [TVTV]\) in third order and four operators \([TTTTV]\, [VTTTV], [TTTV], [VVT]\) in fourth order. The last two are just \([TTV]\) and \([VTV]\), which resemble second order errors for a new potential
V_1. To have a sixth order algorithm, one must eliminate these four error terms. Since \([TTV_1]\) and \([VT^3V]\) are linear in \(V_1\), they can always be eliminated by including sufficient number of \(V_1\) operators in the factorization process. The remaining error terms \([T^4V]\) and \([VT^3V]\) are unaffected by \(V_1\) and can only be eliminated by the choice of coefficients \(\{t_i, v_i\}\). Thus we can apply our previous strategy of dealing only with coefficients \(\{t_i, v_i\}\) but now computing the error coefficient \(e_{VT^nV}\) explicitly.

A careful reexamination of our proof for the Sheng-Suzuki theorem shows that we have proved more than that’s required. The minimization procedure produces a lower bound for \(e_{VT^nV}\), whereas the Sheng-Suzuki theorem only requires that \(e_{VT^nV}\) not be zero. The expansion \(2.15\) merely served as a vehicle for demonstrating that, for any \(\{u_i\}\) satisfying \(2.15\) and \(2.16\), \(e_{VT^nV}\) cannot vanish for positive \(\{t_i\}\). We do not really need to minimize anything, or to determine an actual lower bound. This suggests a simple strategy for proving the sixth order case. It is sufficient to show that \(e_{VT^nV}\) cannot vanish for any set of \(\{u_i\}\) satisfying higher order constraints.

IV. PROVING THE SIXTH ORDER CASE

As discussed in the last section, for a sixth order algorithm, a symmetric factorization must satisfy, in addition to \(2.15\) and \(2.16\), the constraint \(2.14\) for \(n = 2\),

\[
\sum_{i=1}^{N} \nabla s_i^3 u_i = \frac{1}{4}. \tag{4.1}
\]

Also, since the operator \(T^4V\) uniquely tracks the commutator \([T^4V]\), the error coefficient \(e_{VT^nV}\) will vanish if the expansion coefficient of \(T^4V\) is 1/5!. This means that factorization coefficients \(\{t_i, v_i\}\) must also obey

\[
\sum_{i=1}^{N} \nabla s_i^3 v_i = \frac{1}{5}. \tag{4.2}
\]

These four constraints \(2.15, 2.16, 2.17,\) and \(2.18\), can be satisfied by the expansion,

\[
u_i = \lambda_1 + \lambda_2 \frac{\nabla s_i^2}{\nabla s_i} + \lambda_3 \frac{\nabla s_i^3}{\nabla s_i} + \lambda_4 \frac{\nabla s_i^4}{\nabla s_i}. \tag{4.3}
\]

We must now demonstrate that in this case, \(e_{VT^nV}\) cannot vanish if \(\{t_i\}\) are all positive.

When \(u_i\) is expanded via \(4.2\), the four constraints \(2.15, 2.16, 2.17,\) and \(2.18\) produce the following set of four linear equations for \(m = 1\) to \(4\),

\[
\sum_{n=1}^{4} G_{mn} \lambda_n = \frac{1}{m+1}. \tag{4.4}
\]

The matrix \(G_{mn}\) is given by

\[
G_{mn} = \sum_{i=1}^{N} \frac{\nabla s_i^m \nabla s_i^n}{\nabla s_i} = 1 + \sum_{i=1}^{N} s_i s_{i-1} \frac{\nabla s_i^{m-1} \nabla s_i^{n-1}}{\nabla s_i}
\]

\[
\equiv 1 + g_{mn}, \tag{4.5}
\]

de to define the reduced symmetric matrix \(g_{mn}\). Since \(G_{1n} = G_{n1} = 1\) (and hence \(g_{1n} = g_{n1} = 0\), we can subtract the first constraint equation

\[
\lambda_1 + \lambda_2 + \lambda_3 + \lambda_4 = \frac{1}{2} \tag{4.7}
\]

from the other three and reduce the system down to three equations for \(m = 2\) to \(4\):

\[
\sum_{n=2}^{4} g_{mn} \lambda_n = \frac{1}{m+1} - \frac{1}{2}. \tag{4.8}
\]

By writing, \(s_i = s_i - \frac{1}{2} \nabla s_i\) and \(s_{i-1} = s_{i-1} - \frac{1}{2} \nabla s_i\) where \(s_i = \frac{1}{2}(s_i + s_{i-1})\), we can systematically expand

\[
\nabla s_i^n = (s_i - \frac{1}{2} \nabla s_i)^n - (s_i - \frac{1}{2} \nabla s_i)^n
\]

\[
= \frac{n!}{1!(n-1)!} s_i^{n-1} \nabla s_i + \frac{n!}{3!(n-3)!2^2} s_i^{n-3} \nabla s_i^3 + \cdots.
\]

When each summant \(\nabla s_i^{m} \nabla s_i^{n} / \nabla s_i\) is expanded and compared with the similarly expanded integral

\[
\int_{s_i}^{s_i^{\infty}} mns_i^{m+n-2} ds = \frac{mn}{m+n-1} \nabla s_i^{m+n-1},
\]

we deduce that

\[
G_{mn} = \frac{mn}{m+n-1}
\]

\[
- \frac{1}{12} mn(m-1)(n-1) \left\{ \sum_{i=1}^{N} s_i^{m+n-4} (\nabla s_i)^3 + A_5 \sum_{i=1}^{N} s_i^{m+n-6} (\nabla s_i)^5 + \cdots \right\}. \tag{4.9}
\]

with

\[
A_5 = \frac{1}{120} [(m+n-4)^2 + (m-2)(2m-7) + (n-2)(2n-7)].
\]

The constant part of the matrix is the continuum limit \((N \to \infty)\) of the sum, which is the integral

\[
\int_{0}^{1} mns_i^{m+n-2} ds = \frac{mn}{m+n-1}.
\]

We will denote this constant part of the matrix as \(G_{nn}^0\). The corresponding continuum part of \(g_{mn}\) is \(g_{mn}^0 = G_{mn}^0 - 1\). The remaining finite parts of \(G_{mn}\) in \(4.9\), which depends explicitly on \(s_i\), will be denoted as \(\delta G_{mn}\). Since \(g_{mn}\) differs from \(G_{mn}\) only by a constant, its finite
part $\delta g_{mn}$ is the same as that of $G_{mn}$, i.e., $\delta g_{mn} = \delta G_{mn}$. By repeated applications of the identity (4.10), one can reduce $g_{mn}$ to a sum of terms of the form

$$\kappa(l, n) = \sum_{i=1}^{N} (s_{i}s_{i-1})^{l} \nabla s_{i}^{n}. \quad (4.10)$$

Since the explicit form of $g_{mn}$ is known via (4.10), these functions are not particularly useful as calculational tools. However, they are very useful in quickly identifying the matrix element of $g_{mn}$ when doing analytical calculations. For later reference, we list below some $g_{mn}$’s in terms of $\kappa(l, n)$:

$$
\begin{align*}
g_{22} &= \kappa(1, 1) \\
g_{23} &= \kappa(1, 2) \\
g_{24} &= \kappa(1, 3) \\
g_{32} &= \kappa(1, 3) + \kappa(2, 1) \\
g_{33} &= \kappa(1, 4) + \kappa(2, 2) \\
g_{34} &= \kappa(1, 5) + \kappa(2, 3) + \kappa(1, 3).
\end{align*}
$$

(4.11)

Note that $g_{22}$ is the $g$ function of the last section. From the general formula (4.10), one finds indeed that $g_{22}^{0} = 1/3$ and

$$\delta g_{22} = -\frac{1}{3} \sum_{i=1}^{N} (\nabla s_{i})^{3} = -\frac{1}{3} \delta g. \quad (4.12)$$

If we only keep the continuum matrix $g_{mn}^{0}$ in (4.10),

$$
\begin{pmatrix}
\frac{1}{4} & \frac{3}{4} & \frac{1}{4} & \frac{1}{4} \\
\frac{1}{4} & \frac{1}{4} & \frac{3}{4} & \frac{1}{4} \\
\frac{1}{4} & \frac{1}{4} & \frac{1}{4} & \frac{3}{4} \\
\frac{1}{4} & \frac{1}{4} & \frac{1}{4} & \frac{1}{4}
\end{pmatrix}

\begin{pmatrix}
\lambda_{2} \\
\lambda_{3} \\
\lambda_{4} \\
\lambda_{4}
\end{pmatrix}

= \begin{pmatrix}
-\frac{1}{4} \\
-\frac{1}{4} \\
-\frac{1}{4} \\
-\frac{1}{4}
\end{pmatrix},
$$

the solution is trivial: $\lambda_{2} = -\frac{1}{4}$, $\lambda_{3} = 0$, $\lambda_{4} = 0$. This suggests that we should also expand each $\lambda_{i}$ into its continuum and finite part: $\lambda_{2} = -\frac{1}{4} + \delta \lambda_{2}$, $\lambda_{3} = \delta \lambda_{3}$, $\lambda_{4} = \delta \lambda_{4}$. For our purpose, it is enough to keep the leading finite size correction term, i.e., we can neglect the terms of the form $\delta g_{mn} \delta \lambda_{k}$. In this case, we just have

$$
\begin{pmatrix}
\frac{1}{4} & \frac{3}{4} & \frac{1}{4} & \frac{1}{4} \\
\frac{1}{4} & \frac{1}{4} & \frac{3}{4} & \frac{1}{4} \\
\frac{1}{4} & \frac{1}{4} & \frac{1}{4} & \frac{3}{4} \\
\frac{1}{4} & \frac{1}{4} & \frac{1}{4} & \frac{1}{4}
\end{pmatrix}

\begin{pmatrix}
\delta \lambda_{2} \\
\delta \lambda_{3} \\
\delta \lambda_{4} \\
\delta \lambda_{4}
\end{pmatrix}

= \begin{pmatrix}
\frac{1}{4} \delta g_{22} \\
\frac{1}{4} \delta g_{23} \\
\frac{1}{4} \delta g_{24}
\end{pmatrix}.
$$

(4.13)

We do not need to solve each $\delta \lambda_{k}$ explicitly; we only need to know that they are proportional to $\delta g_{2n}$. Since $\lambda_{1} + \lambda_{2} + \lambda_{3} + \lambda_{4} = \frac{3}{4}$, this also implies that $\lambda_{1} = 1 + \delta \lambda_{1}$ with

$$
\delta \lambda_{1} + \delta \lambda_{2} + \delta \lambda_{3} + \delta \lambda_{4} = 0. \quad (4.14)
$$

The above discussion suggests that one should also separate $u_{i}$ into its continuum and finite part,

$$
u_{i} = (1 - \frac{1}{2} \frac{\nabla s_{i}^{2}}{\nabla s_{i}}) + \delta u_{i}.
$$

The constraints on $u_{i}$ now translate into constraints on $\delta u_{i}$:

$$
\begin{align*}
\sum_{i=1}^{N} \nabla s_{i}^{1} \delta u_{i} &= \frac{1}{n+1} - \sum_{i=1}^{N} \nabla s_{i}^{1} (1 - \frac{1}{2} \frac{\nabla s_{i}^{2}}{\nabla s_{i}}) \\
&= \frac{1}{n+1} - (1 - \frac{1}{2} G_{2n}) = \frac{1}{2} \delta g_{2n}.
\end{align*}
$$

(4.16)

Recall that since $g_{1n} = g_{n1} = 0$, we also have $\delta g_{1n} = \delta g_{n1} = 0$. The above constraints for $\delta u_{i}$ is exact. We have not yet invoked any particular representation for $\delta u_{i}$.

To illustrate how this formalism will be used, let’s recompute the quadratic form of the last section:

$$
\begin{align*}
\sum_{i=1}^{N} \nabla s_{i} u_{i}^{2} &= \sum_{i=1}^{N} \nabla s_{i} [(1 - \frac{1}{2} \frac{\nabla s_{i}^{2}}{\nabla s_{i}}) + \delta u_{i}]^{2} \\
&= \frac{1}{2} \sum_{i=1}^{N} \frac{\nabla s_{i}^{2} \nabla s_{i}^{2}}{\nabla s_{i}} + 2 \sum_{i=1}^{N} \nabla s_{i} \delta u_{i} - \sum_{i=1}^{N} \nabla s_{i}^{2} \delta u_{i} + O(\delta u_{i}^{2}) \\
&= \frac{1}{4} G_{2n} - \frac{1}{2} \delta g_{2n} = \frac{1}{3} - \frac{1}{4} \delta g_{22} = \frac{1}{3} + \frac{1}{12} \delta g. \quad (4.17)
\end{align*}
$$

This then implies that

$$
u_{VT} = -\frac{1}{24} \sum_{i=1}^{N} t_{i}^{2}. \quad (4.19)
$$

The first key observation is Eq. (4.17): to leading order in $\delta g_{2n}$, this quadratic form only depends on the first two constraints on $\delta u_{i}$. Its leading finite part is unchanged by additional, higher order constraints on $\delta u_{i}$. That is, $\delta u_{i}$ can be very general. By inspection, $\nu_{VT}$ above cannot vanish for positive $\{t_{i}\}$. Thus this leading order calculation, while not sufficient to determine the exact lower bound for $\nu_{VT}$, it is sufficient to show that $\nu_{VT}$ cannot vanish, and thus proving the Sheng-Suzuki theorem.

Secondly, if $\delta u_{i}$ were to be represented as

$$
\delta u_{i} = \delta \lambda_{2} (\frac{\nabla s_{i}^{2}}{\nabla s_{i}} - 1) + \delta \lambda_{3} (\frac{\nabla s_{i}^{3}}{\nabla s_{i}} - 1) + \delta \lambda_{4} (\frac{\nabla s_{i}^{4}}{\nabla s_{i}} - 1), \quad (4.20)
$$

then in order for the constraints (4.10) to determine $\delta \lambda_{k}$ to the same leading order in $\delta g_{2n}$ as in (4.13) it is enough to compute only the constant (continuum) part of any sums multiplying $\delta \lambda_{k}$. This implies that we may replace any such sum by its integral, or by any other sum having the same integral. Thus for any sum multiplying $\delta u_{i}$, we may replace it by another sum having the same integral. This crucial simplification makes it unnecessary to solve for each $\lambda_{k}$ explicitly.

To compute the error coefficient $\nu_{VT}$, one must use an operator that tracks the commutator $[VT^{3}V]$ uniquely. The analogous operator $T^{3}V^{2}$, whose expansion coefficient is easy to compute, is no longer suitable. Let $C_{VT^{3}V}$ denote its expansion coefficient in terms of
\begin{equation}
C_{VT^3V} = \frac{1}{5!} - \frac{1}{3!} e_{VT} - e_{T^2VT} - e_{VT^3V}. \tag{4.21}
\end{equation}

It is difficult to disentangle \( e_{VT^3V} \) from the contaminating effects of \( e_{VT} \) and \( e_{T^2VT} \). The three operators that track \( |VT^3V| \) uniquely are \( VT^3V, VT^2VT, \) and \( TVT^3V \). We choose the symmetric choice \( VT^3V \), whose coefficient is related to \( e_{VT^3V} \) by

\begin{equation}
C_{VT^3V} = \frac{1}{5!} + 2e_{VT^3V}. \tag{4.22}
\end{equation}

From the left hand side of (3.2), one deduces

\begin{equation}
C_{VT^3V} = \frac{1}{3!} \sum_{i=1}^{N-1} v_i \sum_{j=i+1}^{N} (s_j - s_i) v_j. \tag{4.23}
\end{equation}

This quadratic form in \( \{v_i\} \) is difficult to work with because it is not diagonal in \( u_i \) or some other variables. In the Appendix, we show that it can be simplified to the following bi-diagonal form,

\begin{equation}
C_{VT^3V} = \frac{1}{3!} \left( 3 \sum_{i=1}^{N} \nabla s_i z_i^2 - \sum_{i=1}^{N} \nabla s_i^3 u_i^2 - \frac{1}{4} \right), \tag{4.24}
\end{equation}

where \( z_i \) is defined by

\begin{equation}
z_i = \sum_{j<i} v_j s_j. \tag{4.25}
\end{equation}

The required coefficient \( e_{VT^3V} \) can now be computed from

\begin{equation}
e_{VT^3V} = \frac{1}{12} \left( 3 \sum_{i=1}^{N} \nabla s_i z_i^2 - \sum_{i=1}^{N} \nabla s_i^3 u_i^2 - \frac{3}{10} \right). \tag{4.26}
\end{equation}

The quadratic form involving \( u_i^2 \) is

\begin{equation}
\sum_{i=1}^{N} \nabla s_i^3 u_i^2 = \sum_{i=1}^{N} \nabla s_i^3 (1 - \frac{1}{2} \nabla s_i^2)^2 + 2 \sum_{i=1}^{N} \nabla s_i^2 \delta u_i - \frac{3}{2} \sum_{i=1}^{N} \nabla s_i^2 \delta u_i + O(\delta u_i^2) \tag{4.27}
\end{equation}

\begin{equation}
= \frac{3}{4} - G_{33} + \frac{1}{4}(G_{33} + G_{24}) + \delta g_{23} - \frac{3}{4} \delta g_{24} \tag{4.28}
\end{equation}

\begin{equation}
= \frac{1}{10} + \frac{1}{4} \delta g_{33} - \frac{1}{2} \delta g_{24}. \tag{4.29}
\end{equation}

In (4.27), we have replaced the sum involving \( \nabla s_i^3 \nabla s_i^2 / \nabla s_i \) by its integral equivalent \( (3/2) \nabla s_i^3 \). Also, we have used the identity

\begin{equation}
\frac{\nabla s_i^3}{\nabla s_i} \left( \frac{\nabla s_i^2 \nabla s_i^2}{\nabla s_i} \right) = \frac{\nabla s_i^3 \nabla s_i^3}{\nabla s_i} + \frac{\nabla s_i^4 \nabla s_i^2}{\nabla s_i} - \nabla s_i^5
\end{equation}

Given the expansion (4.3) for \( u_i \), we can deduce the corresponding expansion for \( z_i \). From (4.25), we can rewrite \( z_i \) as

\begin{equation}
z_i = u_i s_i + \sum_{j<i+1}^{N} u_j \nabla s_j. \tag{4.29}
\end{equation}

For \( u_i = \lambda_n \nabla s_i^n / \nabla s_i \), we have

\begin{equation}
z_i = \lambda_n \left[ \frac{\nabla s_i^n}{\nabla s_i} s_i + (1 - s_i^n) \right], \tag{4.30}
\end{equation}

\begin{equation}
= \lambda_n \left[ (s_i^{n-1} + s_i - 1) \frac{\nabla s_i^{n-1}}{\nabla s_i} s_i + (1 - s_i^n) \right], \tag{4.31}
\end{equation}

\begin{equation}
= \lambda_n \left[ 1 + s_i s_i^{n-1} \frac{\nabla s_i^3}{\nabla s_i} \right]. \tag{4.32}
\end{equation}

Hence corresponding to (4.3), \( z_i \) has the expansion

\begin{equation}
z_i = \lambda_1 + \lambda_2 (1 + s_i s_i-1) + \lambda_3 (1 + s_i s_i-1) \frac{\nabla s_i^3}{\nabla s_i} + \lambda_4 (1 + s_i s_i-1) \frac{\nabla s_i^3}{\nabla s_i}. \tag{4.33}
\end{equation}

One can check that this form for \( z_i \) satisfies the four constraints (4.3), (4.10), (4.11), and (4.2) when they are expressed in terms of \( z_i \):

\begin{equation}
z_1 = \lambda_1 + \lambda_2 + \lambda_3 + \lambda_4 = \frac{1}{2}
\end{equation}

and for \( m = 1 \) to \( 3 \),

\begin{equation}
\sum_{i=1}^{N} \nabla s_i^m z_i = \frac{1}{m+2}. \tag{4.34}
\end{equation}

The identity (4.6) is needed to show that (4.32) is equivalent to the last three constraint equations for \( u_i \). As in the case of \( u_i \), we can write \( z_i \) in the form

\begin{equation}
z_i = \frac{1}{2} (1 - s_i s_i-1) + \delta z_i \tag{4.35}
\end{equation}

and transfer the last three constraints on \( z_i \) to \( \delta z_i \),

\begin{equation}
\sum_{i=1}^{N} \nabla s_i^{n-1} z_i = \frac{1}{2} \delta g_{2n}. \tag{4.36}
\end{equation}

The quadratic form for \( z_i \) is then

\begin{equation}
\sum_{i=1}^{N} \nabla s_i z_i^2 = \sum_{i=1}^{N} \nabla s_i (1 - s_i s_i-1)^2 + \sum_{i=1}^{N} \nabla s_i \delta z_i
\end{equation}

\begin{equation}
- \sum_{i=1}^{N} \nabla s_i (s_i s_i-1) \delta z_i + O(\delta z_i^2)
\end{equation}

\begin{equation}
= \frac{1}{4} - \frac{1}{2} \kappa(1,1) + \frac{1}{4} \kappa(2,1) + \frac{1}{2} \delta g_{22} - \frac{1}{3} \sum_{i=1}^{N} \nabla s_i^3 \delta z_i
\end{equation}

\begin{equation}
= \frac{1}{4} - \frac{1}{2} g_{22} + \frac{1}{4} (g_{33} - g_{24}) + \frac{1}{2} \delta g_{22} - \frac{1}{6} \delta g_{24}
\end{equation}

\begin{equation}
= \frac{2}{15} + \frac{1}{4} g_{33} - \frac{5}{12} \delta g_{24}. \tag{4.37}
\end{equation}
We have again replaced the sum involving $\nabla s_i(s_i,s_{i-1})$ by its integral equivalent $(1/3)\nabla s_i^3$ and used (4.14) to express the required sum in terms of $g_{mn}$’s. Thus the bi-diagonal form is

$$3 \sum_{i=1}^{N} \nabla s_i z_i^2 - \sum_{i=1}^{N} \nabla s_i^3 u_i^2 = \frac{3}{10} + \frac{1}{4}(2\delta g_{33} - 3\delta g_{24}).$$

From (4.9), we find,

$$\delta g_{33} = -3 \sum_{i=1}^{N} s_i^2 \frac{3}{4} (\nabla s_i)^3 - \frac{1}{20} \sum_{i=1}^{N} (\nabla s_i)^5$$

$$\delta g_{24} = -2 \sum_{i=1}^{N} s_i^2 \frac{3}{4} (\nabla s_i)^3 - \frac{1}{10} \sum_{i=1}^{N} (\nabla s_i)^5,$$  

and therefore finally,

$$e_{VT^3V} = \frac{1}{240} \sum_{i=1}^{N} (\nabla s_i)^5 = \frac{1}{240} \sum_{i=1}^{N} t_i^5!$$  

This is remarkably similar to (4.19). Thus if $\{t_i\}$ are all positive, then $e_{VT^3V}$ cannot vanish. No sixth order positive factorization scheme is possible without including the commutator $V_3 = [VT^3V]$.

\section{Beyond Sixth Order}

In Sections II, we have shown that in order to have a fourth order forward algorithm, one must include the commutator $V_1 = [VT^3V]$ in the factorization process. In the last section, we have proved that in order to have a sixth order forward algorithm one must include in addition to $V_1$, the commutator $V_3 = [VT^3V]$. By repeating the same argument, it is not difficult to discern the pattern of higher order forward algorithms. In going from the $(2n)$\textsuperscript{th} to the $(2n+2)$\textsuperscript{th} order, one must add a new commutator $V_{2n-1} = [VT^{2n-1}V]$ to the factorization process. A proof of this general result is a straightforward generalization of our approach in the last section, but technically much more involved. For example, to prove the eighth order case, we must track $e_{VT^5V}$ uniquely via the operator $VT^5V$’s coefficient given by $S_3/5!$, where $S_3$ as shown in the Appendix, is tri-diagonal in $u_i$, $z_i$ and

$$y_i = \sum_{j=1}^{N} v_j s_j^2.$$  

One then has to work out the expansion for $y_i$ as in the case of $z_i$. Moreover, since $e_{VT^3V}$ is anticipated to be $\propto \sum_{i=1}^{N} (\nabla s_i)^7$, one can no longer ignore contribution of order $(\delta u_i)^2 \propto (\sum_{i=1}^{N} (\nabla s_i)^3)^2$. Thus the current formalism, while powerful in determining $e_{VT^3V}$ variationally and $e_{VT^5V}$ perturbatively, is too demanding for the general case. To prove such a general result, one must find a less explicit approach.

\section{Conclusions}

In this work, we have introduced a framework for analyzing and understanding the structure of factorized algorithms. There are three key ideas: 1) The order constraints and error coefficients can be tracked by operators and expressed directly in terms of factorization coefficients. 2) By introducing a suitable representation for the factorization coefficients, the order constraints and error terms can be solved analytically. 3) For many purposes, it is sufficient to determine the error coefficients perturbatively. This last point is specially important. All previous works on factorization algorithms are based on exact decompositions. Since this is difficult to do analytically, one can make little progress except numerically. This work shows that a leading order calculation is sufficient to establish most of the important results we know about these algorithms. In particular, we have provided a constructive proof of the Shang-Suzuki theorem. Most importantly, we have shown that in order to have a sixth order forward time step algorithm, one must include the commutator $[VT^3V]$ in the factorization process.

This work suggests that there is regularity to the existence of forward algorithms. In order to have only positive time steps, one must continue to enlarge one’s collection of constituent operators for factorizing $e^{(T+V)}$. For a $(2n)$\textsuperscript{th} order forward algorithm one must include all commutators of the form $[VT^{2k-1}V]$ from $k = 1$ to $k = n - 1$, in addition to $T$ and $V$. The proof of this general result is currently beyond scope of our perturbative approach. Moreover, the massive cancellations that produced the sixth order result (4.37) strongly suggest that a better formulation, with these cancellations built-in, must be possible. This work suggests that a more powerful way of understanding the structure of these algorithms is still waiting to be found.

The need to include $[VT^3V]$ make it difficult to construct, but does not necessarily preclude the possibility of a sixth order forward algorithm. One simply has to work harder to devise practical ways of obtaining $[VT^3V]$ without computing it directly. Work is currently in progress toward this goal.

\section*{Acknowledgments}

I thank Harald Forbert for pointing out the inadequacy of an earlier version of this work and for many stimulating discussions. This work is supported, in part, by a National Science Foundation grant, No. DMS-0310580.
APPENDIX A: COEFFICIENT OF $VTV$, $VT^3V$ AND $VT^3V$

There is a systematic way of diagonalizing the sum

$$S_m = \sum_{i=1}^{N-1} \sum_{j=i+1}^{N} v_i (s_j - s_i)^m v_j$$

needed in computing the error coefficients $e_{VTV}$. The above is a sum over the upper triangle of a $N \times N$ square matrix and can be denoted more simply as $\sum_{j>i}$.

The general form we need to diagonalize is

$$S(f, g) = \sum_{j>i} f_j (g_j - g_i) f_j = \sum_{i>j} f_j g_i f_i - \sum_{j>i} f_j g_i f_j$$  \hspace{1cm} (A1)$$

where we have interchanged the summation indices in the first term on the right-hand-side. The key point here is that if we introduce a new variable

$$h_i = \sum_{j=i}^N f_j,$$

such that $f_i = h_i - h_{i+1}$, then the second term on the right hand side of (A1) is only a single sum. The first term can be eliminated by completing the "square matrix". Let $\sum_i f_i g_i = P$ and $\sum_j f_j = F$ be known sums, then

$$PF = \sum_i f_i g_i \sum_j f_j = \sum_i f_i^2 g_i + \sum_{i>j} f_i g_i f_j + \sum_{j>i} f_j g_i f_j.$$  \hspace{1cm} (A2)$$

Subtracting (A1) from (A2) gives

$$PF - S(f, g) = \sum_i f_i^2 g_i + 2 \sum_i f_i g_i f_j$$

$$= \sum_{i=1}^N g_i (h_i - h_{i+1})^2 + 2 \sum_{i=1}^N g_i (h_i - h_{i+1}) h_{i+1}$$

$$= \sum_{i=1}^N g_i (h_i^2 - h_{i+1}^2) = \sum_{i=1}^N \nabla g_i h_i^2,$$  \hspace{1cm} (A3)$$

and hence,

$$S(f, g) = PF - \sum_{i=1}^N \nabla g_i h_i^2$$  \hspace{1cm} (A4)$$

For the case of $m = 1$, we have $f_i = v_i$, $g_i = s_i$, $h_i = u_i$, $F = 1$ from (2.53), and $P = \left(\frac{1}{2} + e_{TV}\right)$ from (2.54). Therefore, we have

$$S_1 = \left(\frac{1}{2} + e_{TV}\right) - \sum_{i=1}^N \nabla s_i u_i^2.$$  

Since the coefficient of $VTV$ is just $S_1 = \frac{1}{2} + e_{VTV}$, the above is identical to (2.12). The use of the more complicated operator $VTV$ determines the same $e_{VTV}$, as it must.

For $m = 3$, we have

$$S_3 = \sum_{j>i} v_i (s_j^3 - s_i^3) v_j - 3 \sum_{j>i} v_i s_i (s_j - s_i) s_j v_j.$$  

Assuming now that all linear constraints on $v_i$ are satisfied up to the relevant order, we have for the first and second term on the right respectively, $f_i = v_i$, $g_i = s_i^3$, $h_i = u_i$, $F = 1$, $P = \frac{1}{4}$ and $f_i = s_i v_i$, $g_i = s_i$, $h_i = z_i$, $F = \frac{1}{2}$, $aP = \frac{1}{3}$. Hence we have

$$S_3 = \frac{1}{4} - \sum_{i=1}^N \nabla s_i u_i^2 - 3 \left(\frac{1}{6} - \sum_{i=1}^N \nabla s_i z_i^2\right),$$  

where

$$z_i = \sum_{j=i} v_j s_j.$$  

The coefficient of $VT^3V$ is $S_3/3!$. Since $[VT^3V]$ contains the operator $VT^3V$ twice, we have

$$\frac{1}{6} S_3 = \frac{1}{3!} + 2 e_{VT^3V},$$

and therefore

$$12 e_{VT^3V} = S_3 - \frac{1}{20} = 3 \sum_{i=1}^N \nabla s_i z_i^2 - \sum_{i=1}^N \nabla s_i u_i^2 - \frac{3}{10}$$  \hspace{1cm} (A5)$$

For the case $m = 5$, we have

$$S_5 = \sum_{j>i} v_i (s_j^5 - s_i^5) v_j - 5 \sum_{j>i} v_i s_i (s_j^3 - s_i^3) s_j v_j$$

$$+ 10 \sum_{j>i} v_i s_i^2 (s_j - s_i) s_j v_j$$  \hspace{1cm} (A6)$$

For the first term we have $f_i = v_i$, $g_i = s_i^5$, $h_i = u_i$, $F = 1$, and $P = \frac{1}{4}$. For the second term we have $f_i = s_i v_i$, $g_i = s_i^3$, $h_i = z_i$, $F = \frac{1}{2}$, and $P = \frac{1}{3}$. For the third term, we have $f_i = s_i^2 v_i$, $g_i = s_i$, $h_i = y_i$, $F = \frac{1}{2}$, and $P = \frac{1}{4}$. We therefore have

$$S_5 = \frac{1}{6} - \sum_{i=1}^N \nabla s_i^5 u_i^2 - 5 \left(\frac{1}{10} - \sum_{i=1}^N \nabla s_i^3 z_i^2\right)$$

$$+ 10 \left(\frac{1}{12} - \sum_{i=1}^N \nabla s_i y_i^2\right)$$

$$= \frac{1}{2} - \sum_{i=1}^N \nabla s_i^5 u_i^2 + 5 \sum_{i=1}^N \nabla s_i^3 z_i^2 - 10 \sum_{i=1}^N \nabla s_i y_i^2,$$

where

$$y_i = \sum_{j=i} v_j s_j^2.$$
