Abstract
The snake venom MT-III is a group IIA secreted phospholipase A2 (sPLA2) enzyme with functional and structural similarities with mammalian pro-inflammatory sPLA2s of the same group. Previously, we demonstrated that MT-III directly activates the innate inflammatory response of macrophages, including release of inflammatory mediators and formation of lipid droplets (LDs). However, the mechanisms coordinating these processes remain unclear. In the present study, by using TLR2−/− or MyD88−/− or C57BL/6 (WT) male mice, we report that TLR2 and MyD88 signaling have a critical role in MT-III-induced inflammatory response in macrophages. MT-III caused a marked release of PGE2, PGD2, PGJ2, IL-1β and IL-10 and increased the number of LDs in WT macrophages. In MT-III-stimulated TLR2−/− macrophages, formation of LDs and release of eicosanoids and cytokines were abrogated. In MyD88−/− macrophages, MT-III-induced release of PGE2, IL-1β and IL-10 was abrogated, but release of PGD2 and PGJ2 was maintained. In addition, COX-2 protein expression seen in MT-III-stimulated WT macrophages was abolished in both TLR2−/− and MyD88−/− cells, while perilipin 2 expression was abolished only in MyD88−/− cells. We further demonstrated a reduction of saturated, monounsaturated and polyunsaturated fatty acids and a release of the TLR2 agonists palmitic and oleic acid from MT-III-stimulated WT macrophages compared with WT control cells, thus suggesting these fatty acids as major messengers for MT-III-induced engagement of TLR2/MyD88 signaling. Collectively, our findings identify for the first time a TLR2 and MyD88-dependent mechanism that underlies group IIA sPLA2-induced inflammatory response in macrophages.

Introduction
Secreted phospholipases A2 (sPLA2) are enzymes that hydrolyse glycerophospholipids at the sn-2 position of the glycerol backbone in a calcium-dependent manner, releasing fatty acids and lysophospholipids. These enzymes are members of the PLA2 superfamily, which is widely distributed in nature, and 15 groups and subgroups have been described, including five categories termed secreted PLA2, cytosolic PLA2, Ca2+ independent PLA2, the platelet-activating factor acetylhydrolase, and lysosomal PLA2 [1]. Among them, group IIA sPLA2 includes mammalian inflammatory-type and Viperid snake venom sPLA2s [2,3]. Besides their relevant role in cell membrane physiology, mammalian group IIA sPLA2s are recognized as important paracrine and autocrine players in inflammatory processes by their ability to release fatty acids from cell membranes, leading to subsequent production of pro-inflammatory mediators such as prostaglandins, leukotrienes [1]. Accordingly, sPLA2 enzymes, particularly group IIA sPLA2s, have been implicated in the pathophysiology of several inflammatory diseases, such as atherosclerosis, inflammatory bowel disease, asthma and arthritis [4,5,6].

Besides structural homology, snake venom group IIA sPLA2s share functional features with mammalian group IIA sPLA2s, owing to their ability to induce inflammatory events in both in vivo and in vitro experimental models [7]. sPLA2s are abundant components in the proteomes of snake venoms from Bothrops genus [8] and have been associated with the prominent local inflammatory effects induced by these venoms. An Asp49 sPLA2, named myotoxin-III (MT-III), has been purified from Bothrops asper snake venom [9]. This group IIIA sPLA2 has been reported to induce inflammatory events in in vivo experimental models [10,11]. Furthermore, this venom sPLA2 exhibits the ability to directly activate inflammatory functions in isolated macrophages, such as increased phagocytic capacity, release of cytokines [11,12], up-regulation of lipid mediator cascade, with release of prostaglandins [13], and increased formation of lipid droplets (LDs) [14], which are organelles implicated in the differentiation of macrophages...
into foam cells. However, the initial steps leading to this sPLA₂-induced activation of macrophages are still unknown.

Macrophages are pivotal cells in innate immune responses. Activation of these cells initiates cascades of events that lead to acute inflammatory processes and the switch from the acute to the resolutive phase of inflammation, by releasing resolutive mediators, such as PGE₂ and IL-10 [15,16]. In addition, macrophages are relevant cells in the development of many chronic inflammatory diseases, such as atherosclerosis. Macrophages loaded with LDs, termed foam cells, constitute an early hallmark of atherosclerotic lesion formation and a major cell source of inflammatory mediators [17,18].

The macrophage innate response is initiated by activation of diverse membrane recognition receptors, such as the Toll-like receptors (TLRs). Nowadays, at least 13 TLRs have been described, each of them with a degree of specificity for various endogenous and exogenous ligands, eliciting different, but sometimes overlapping, immune responses [19,20]. In inflammatory processes, recognition of pathogen-associated molecular patterns (PAMPs) by TLRs except TLR3 activates cell-signaling pathways mediated by the MyD88 [20]. Other kinds of stimuli, named endogenous damage-associated molecular patterns (DAMPs), are also capable of activating MyD88-dependent innate immune signaling by TLRs [21]. Some of the well-characterized DAMPs include: fibronectins [22], heat-shock proteins [23], pro-inflammatory cytokines from the monocyte-macrophage system [24], and free fatty acids (FFA) [25]. Among the TLRs, TLR2 constitutes a molecular link between elevated circulating FFA and inflammation [26–28]. TLR2 binds lipid-based structures via their long-chain saturated FFA moieties [25,29], triggering inflammatory responses through MyD88 signaling [30]. Although TLRs are critical receptors directing specific inflammatory programs in macrophages, the involvement of TLR2 and MyD88 adaptor molecule signaling pathways in the activation of macrophages by group IIA sPLA₂ remains unknown. The understanding of the mechanisms(s) involved in sPLA₂-induced activation of in a pivotal innate immune cell, such as the macrophage, shall provide valuable information on new targets to confront the inflammatory diseases where group IIA sPLA₂ enzymes are involved.

In the present study the involvement of TLR2 and MyD88 adaptor molecule in the signaling cascade (inflammatory signaling) elicited by MT-III in macrophages was investigated. To test this possibility, the effects of MT-III in macrophages from wild-type (WT) C57BL/6 mice, TLR2 gene knockout (TLR2-/-) mice and MyD88 gene knockout (MyD88-/-) C57BL/6 mice were evaluated in terms of PGE₂, PGD₂, PGJ₂, IL-1β and IL-10 enzyme immunoassay kits and polyclonal antibodies against COX-2 and perilipin-2 expression and release of free fatty acids. Furthermore, COX-2 and perilipin-2 expression and release of free fatty acids. Herein, we present the first evidence that TLR2 and MyD88 adaptor molecule are implicated in the inflammatory response triggered by a group IIA sPLA₂ enzyme in macrophages. Engagement of TLR2/MyD88 signaling pathway by the venom sPLA₂ MT-III coordinates events related to both initiation and resolution of the inflammatory response in macrophages. Our observations also suggest that saturated free fatty acids are major agonists for engagement of TLR2/MyD88 pathway induced by this group IIA sPLA₂.

Materials and Methods

Ethics Statement

This study includes experiments with macrophages collected from pathogen-free 5-week-old wild type (WT), MyD88-/- and TLR2-/- mice (all on a C57BL/6 genetic background). These animals were bred in animal facilities at the University of São Paulo and were housed in a temperature-controlled room (22–24°C) with a 12 h light-dark cycle and fresh water and food ad libitum until used. All experimental procedures involving these animals were performed in accordance with the procedures laid down by the Universities Federation for Animal Welfare and were approved by the Animal Experimentation Ethics Committee of University of São Paulo (São Paulo, Brazil; Reference No 94/2010).

Chemicals and Reagents

Hema-3 stain from Biochemical Sciences (Swedesboro, NJ, USA). MTT and L-glutamine were obtained from USB (Cleveland, OH, USA). E-toxate LAL kit and mouse mAb anti-β-actin was purchased from Sigma-Aldrich (St. Louis, MO, USA) and guinea pig polyclonal antibody anti-mouse perilipin-2 (PLIN2) from Research Diagnostics (Flanders, NJ, USA). PGE₂ and PGD₂ enzyme immunoassay kits and polyclonal antibodies against COX-2 were purchased from Cayman Company, Ann Arbor, MI, USA. 15-deoxy-A[12,14] prostaglandin E₂ (PGJ₂) and IL-10 and IL-1β enzyme immunoassay kits were purchased from Eazo Life Sciences (Ann Arbor, MI, USA) and eBioscience, Inc. (San Diego, CA, USA), respectively. Secondary antibodies, anti-mouse and anti-guinea pig, conjugated to HRP and nitrocellulose membrane, were obtained from GE Healthcare (Buckinghamshire, UK). Gentamicin was purchased from Schering-Plough (Whitehouse Station, NJ, USA) and DMSO from Amresco (Solon, OH, USA). RPMI 1640, thiocarboxyhydrate, and Osmium tetroxide (OsO₄) were purchased from Sigma-Aldrich and RPMI from Life Technologies (São Paulo, SP, Brazil). Chloroform and methanol (HPLC grade) were purchased from Fisher Scientific (Hampton, NH), and [1-14C] palmitic acid and oleic acid from Perkin Elmer (Waltham, MA). Silicagel thin layer chromatography plates were purchased from Macherey-Nagel (Düren, Germany). Thioglycolate was obtained from Merck (Darmstadt, Germany) and all salts used were purchased from Sigma-Aldrich.

Phospholipase A₂ (sPLA₂)

Aspartate-49 sPLA₂ named MT-III (Uniprot accession no.: P20474) from B. asper venom was purified by ion-exchange chromatography on CM-Sephadex C-25, using a KCl gradient from 0 to 0.75 M at pH 7.0 as described [2], followed by RP-HPLC on a semi-preparative C8 column (Vydac; 10×250 mm, 5 μm particle size) eluted at a flow rate of 2.5 ml/min with a gradient of acetoni-trile (0–70%, containing 0.1% trifluoroacetic acid) over 30 min. Homogeneity was verified by SDS-PAGE run under reducing conditions, in which a single band of ~14 kDa was observed. The complete amino acid sequence of this enzyme has been described previously [31,32]. The absence of endotoxin contamination in the MT-III batches used was demonstrated by performing the quantitative LAL test [33], which revealed undetectable levels of endotoxin (<0.125 EU/ml).

Macrophages Harvesting and Stimulation

Animals were killed under CO₂ atmosphere and cells were then harvested by washing peritoneal cavities with 3 mL aprotic phosphate buffered saline (PBS), pH 7.2. Aliquots of the washes were used for total cell counts in a Neubauer chamber, after dilution (1:20, v/v) in Turk solution (0.2% crystal violet dye in 30% acetic acid). Differential cell counts were performed on smears stained with Hema3. More than 95% of the cell population consisted of macrophages, as determined by conventional morphological criteria. The remaining wash volumes were centrifuged at 129×g for 6 min (4°C), supernatants were discarded and cell pellets were appropriately diluted and maintained in serum-free...
RPMI 1640 medium, supplemented with 2 mM L-glutamine and 40 μg/mL gentamicin sulfate at 37°C with 5% CO₂, and processed according to the experimental protocols used, as follows: 1) 1 x 10⁶ macrophages/well were seeded in 12 wells culture plates and maintained in culture medium for 24 h before stimulation, and then used for Western blotting analysis of COX-2 and perilipin-2 protein expression; 2) 2 x 10⁵ macrophages, harvested 4 days after i.p. injection of 1 mL 3% thioglycolate, were seeded on glass coverslips and incubated in culture medium for 30 min for adhesion, followed by washing with PBS, and then used for LDs evaluation; 3) 1 x 10⁶ macrophages were seeded in cell culture dish, maintained in culture medium for 18 h, and used for gas chromatography/mass spectrometry analysis of fatty acid methyl esters; 4) 2 x 10⁵ macrophages/well were seeded in 12 well culture plates, maintained with culture medium for 30 min for adhesion and then incubated with exogenous [1–14C] Oleic or [1–14C] Palmitic acid (1 μM; 0.25 μCi/ml) for 18 h at 37°C. Cells were then scraped with 0.1% Triton X-100 in PBS and supernatants were removed and total 14C-radioactivity levels were determined by scintillation counting. After each of the above described procedures, cells were stimulated with MT-III diluted in RPMI 1640 medium in a final concentration of 0.4 μM or RPMI 1640 medium alone (control) for selected periods of time and maintained at 37°C in a humidified atmosphere (5% CO₂).

Quantification of Eicosanoids and Cytokines
Prostaglandins (PGE₂, PGD₂ and PGI₂) and cytokines (IL-1β and IL-10) were quantified in supernatants from macrophages cultures by using commercially available enzyme immuno assay kits, performed according to instructions of the manufacturer.

Lipid Droplet (LD) Staining and Quantification
Analysis of LD numbers was performed in osmium-stained cells. In brief, macrophages adhered to glass coverslips were fixed in 4% paraformaldehyde in 0.1 M phosphate buffer (pH 7.2) for 15 min and stained with OsO₄. The coverslips were then rinsed in 0.1 M phosphate buffer, stained with 1% OsO₄ (30 min), rinsed in deionized H₂O, immersed in 1.0% thiocarbohydrazide (5 min), rinsed again in 0.1 M phosphate buffer, re-stained with 1% OsO₄ (3 min), rinsed with H₂O, and then dried and mounted [42]. The morphology of the fixed cells was observed, and round intracellular osmiophilic structures were identified as LDs, which were then counted under phase-contrast microscopy using the 100 x objective lens in 50 consecutively scanned leukocytes in each coverslip.

Western Blotting for COX-2 and Perilipin-2
COX-2 and perilipin-2 protein levels in cultured macrophages were detected by Western blotting. Aliquots of MT-III-stimulated and non-stimulated cells (1.5 x 10⁶ cells) were lysed with 100 μL sample buffer (0.5 M Tris-HCl, pH 6.8, 20% SDS, 1% glycerol, 1 M β-mercapto ethanol, 0.1% bromophenol blue) and boiled for 10 min. Samples were resolved by SDS-PAGE on 10% bis-acrylamide gels overlaid with a 5% stacking gel. Proteins were then transferred to nitrocellulose membranes using a Mini Trans-Blot (Bio-Rad Laboratories, Richmond, CA, USA). The membranes were blocked for 1 h with 5% nonfat dry milk in Tris-buffered saline (TBS) (20 mM Tris, 100 mM NaCl, and 0.5% Tween 20, pH 7.2), and incubated with primary antibodies against COX-2 (1:1000 dilution), perilipin-2 (1:2000) and β-actin (1:3000) for 1 h. They were then washed and incubated with the appropriate secondary antibody conjugated to horseradish peroxidase. The immunoreactive bands were detected by the entry-level peroxidase substrate for enhanced chemiluminescence (ECL), according to the instructions of the manufacturer (GE Healthcare). Band densities were quantified with a GS 700 densitometer (Bio-Rad Laboratories) using the image analysis software Molecular Analyst (Bio-Rad Laboratories).

Gas Chromatography/mass Spectrometry Analysis of Fatty Acid Methyl Esters
A cell extract was used and, before extraction, 10 nmol of 1,2,3-trihexadecanoylglycerol was added as internal standard. Then, total lipids were extracted according to the Bligh and Dyer method [34], and glycerolipids were transmethylated with 500 μl of 0.5 M KOH in methanol for 60 min at 37°C. For neutralization, 500 μl of 0.5 M HCl were added and the extraction of fatty acid methyl esters was performed with 1 ml of n-hexane twice. Analysis of fatty acid methyl esters was carried out in a Agilent 7890A gas chromatograph coupled to an Agilent 5975C mass-+-selective detector operated in electron impact mode (EI, 70 eV), equipped with an Agilent 7693 autosampler and an Agilent DB23 column (60 m length x 250 μm internal diameter x 0.15 μm film thickness) under the following conditions: oven temperature was held at 50°C for 1 min, then increased to 175°C at a rate of 25°C/min, then increased to 215°C at a rate of 1.5°C/min, and the final ramp being reached at 235°C at a rate of 10°C/min. The final temperature was maintained for 5 min, and the run time was 39.67 min. Data analysis was carried out with the Agilent G1701EA MSD Productivity Chemstation software, revision E.02.00, and the quantification of fatty acid methyl esters was achieved by integration of chromatographic peaks comparing with authentic analytical standards [35,36]. The fatty acids achieved are indicated below in table 1.

Quantification of Fatty Acids (FA) Released
The cells were placed in serum-free medium and exposed to exogenous [14C] Oleic or [14C] Palmitic acid (1 μM; 0.25 μCi/ml) for 18 h at 37°C. Afterward, the cells were washed four times with PBS containing 0.5% albumin to remove the fatty acids that had not been incorporated, and then stimulated with MT-III or RPMI medium only (control) for 6 h. Cells were scraped with 0.1% Triton X-100 in PBS, supernatants were removed, and total 14C-radioactivity levels were determined by scintillation counting.

Statistical Analysis
Data are expressed as the mean ± standard error of mean (S.E.M) of at least three animals. Multiple comparisons among groups were performed using one-way ANOVA and Tukey test as a post-test. Differences between experimental groups were considered significant for P-values <0.05. All statistic tests were performed using Prism version 5 software (GraphPad, San Diego, CA).

Results
Prostaglandin Production Induced by MT-III Requires Distinct TLR Signaling Pathways
Prostaglandins are produced in abundance at sites of inflammation and regulate many aspects of the inflammatory response. Prostaglandins such as PGE₂ and PGD₂ have well-defined roles in acute inflammation, such as the regulation of blood flow and edema formation, cytokine generation, and leukocyte migration [37,38]. In contrast to these lipid mediators, PGJ₂, which is a PGD₂-derived prostanoid, has been described as a resolutive mediator, which is involved in the switch from the acute into the regenerative phases of inflammatory processes [16]. We have
previously reported that the sPLA₂ MT-III elicits the biosynthesis of prostaglandins in isolated peritoneal macrophages [13]. These relevant cells of the innate immune system sense danger signals via recognition receptors such as TLRs, and then initiate a coordinated inflammatory response. However, whether TLR pathways, particularly TLR2 and MyD88 adaptor molecule activation, are required for this and other MT-III-induced effects in macrophages is unknown, and deserve further investigation. Therefore, we initially evaluated the involvement of TLR2 and MyD88 signaling in MT-III-induced PGE₂, PGD₂ and PGI₂ production in TLR2- and MyD88-deficient macrophages. Results presented in Figure 1 (A–C) show that PGE₂ levels were significantly increased in MT-III-stimulated macrophages collected from WT mice. This MT-III- induced PGE₂ release was impaired in macrophages obtained either from TLR2−/− or MyD88−/− mice. Notably, sPLA₂ MT-III failed to induce PGD₂ and PGI₂ production in TLR2−/−, but did induce production of these mediators in MyD88−/− macrophages when compared with MT-III- stimulated WT cells. These observations prompted us to consider that TLR2 signaling is engaged for the biosynthesis of PGE₂, PGD₂ and PGI₂ in macrophages under stimuli by MT-III. However, the TLR2 via MyD88 adaptor molecule pathway operates only for biosynthesis of PGE₂, whereas production of PGD₂ and PGI₂ occurs through an adaptor molecule other than MyD88. Of note, these findings further suggest that upon activation by the sPLA₂ MT-III, TLR2 and MyD88 signaling pathways can coordinate macrophage responses related to both the development and resolution steps of inflammation.

Up-regulation of COX-2 Protein Expression Induced by MT-III is Dependent on TLR2 via MyD88 Signaling Pathway

Activation of TLR2 via MyD88-mediated signaling leads to activation of transcription factors such as NF-κB, AP-1 and IRF, which in turn play an important role in gene transcription of several molecules involved in the inflammatory response, such as cytokines and cyclooxygenase-2 (COX-2) [39–42]. Prostaglandins are produced by cyclooxygenases, which occur in constitutive (COX-1) and inducible (COX-2) forms [6]. We have previously demonstrated that MT-III up-regulates COX-2 protein expression in peritoneal macrophages and that this isomer is responsible for the increased levels of prostaglandins induced by this sPLA₂ [13]. However, the involvement of TLR2 and MyD88 signaling pathway in this process is unknown. The potential role of TLR2 and MyD88 signaling in MT-III-induced COX-2 protein expression was then analyzed. Figure 1 (D) shows that TLR2−/− and MyD88−/− macrophages stimulated by MT-III did not present the increased COX-2 protein expression seen in MT-III-stimulated WT macrophages. These data clearly indicate that TLR2 and MyD88 are essential to this effect induced by the sPLA₂ MT-III, constituting a key step in the onset of MT-III-induced activation of macrophages. Participation of MyD88 signaling in this MT-III-induced effect is consistent with previous reports by others that activation of this adaptor molecule signals for gene expression of COX-2 [19,43].

TLR2 via MyD88 Signaling Pathway is Required for MT-III-induced Production of IL-1β and IL-10 in Macrophages

IL-1β and IL-10 are relevant mediators involved in triggering and down-regulation of inflammatory processes, respectively [44,45]. Despite the distinct roles played by these two cytokines in inflammation, the production of these mediators has been shown to be regulated by TLR2 and MyD88 signaling [46]. The ability of MT-III to induce the release of inflammatory cytokines, such as IL-1β, has been previously demonstrated [12]. However, whether this MT-III-induced event is coordinated by TLR2 and MyD88 pathways is unknown. Moreover, neither the ability of MT-III to induce release of IL-10 by macrophages nor the participation of TLR2 and MyD88 pathways in this effect has been investigated. We therefore explored the potential role of TLR2 and MyD88 signaling in MT-III-induced synthesis of these cytokines. As demonstrated in Figure 2 (A–B), stimulation of WT macrophages with MT-III induced a significant release of IL-1β and IL-10 from these cells. However, stimulation of TLR2−/− and MyD88−/− macrophages by MT-III did not result in an increased release of these two cytokines as compared with MT-III-stimulated WT macrophages. These data confirm previous observations on the ability of MT-III to induce the release of IL-1β and additionally evidenced the capacity of this sPLA₂ to induce the release of IL-10. Furthermore, these data imply the TLR2 via MyD88 signaling pathway in the generation of IL-1β and IL-10 induced by MT-III in macrophages.

### Table 1. Fatty acid nomenclature.

| Abbreviation | Systematic Name | Commom name |
|--------------|-----------------|-------------|
| 16_0         | Hexadecanoic Acid | Palmitic acid |
| 18_0         | Octadecanoic Acid | Stearic acid |
| 18_1 n-9     | 9-Octadecenoic Acid | Oleic acid |
| 18_1 n-7     | 11-Octadecenoic Acid | cis-vaccenic acid |
| 18_2 n-6     | 9,12-Octadecadienoic Acid | Linoleic acid |
| 20_1 n-9     | 11-Eicosenoic Acid | Gondoic Acid |
| 20_2 n-6     | 11,14-Eicosadienoic Acid | none |
| 20_3 n-6     | 8,11,14-Eicosatrienoic Acid | Dihomo-gamma-linolenic acid |
| 20_4 n-6     | 5,8,11,14-Eicosatetraenoic Acid | Arachidonic acid |

TLR2 via MyD88 is a Critical Pathway for MT-III-induced LD Formation

It has been demonstrated that LDs formation in leukocytes is a highly regulated event that depends on the interaction of cellular receptors with their ligands. These organelles were shown to be involved in the synthesis of inflammatory mediators and are markers of leukocyte activation [47,48]. Moreover, the role of TLRs-mediated pathogen recognition and activation in the mechanism of LDs formation has been demonstrated by others [48,49]. We have recently shown that MT-III induces the formation of LDs in macrophages [14]. However, the mechanisms underlying this MT-III-induced effect remain unclear. To further understand this issue we investigated the involvement of TLR2 and MyD88 signaling. As demonstrated in Figure 3A, the sPLA₂ MT-III failed to induce LDs formation in macrophages from both TLR2⁻/⁻ and MyD88⁻/⁻ mice when compared with macrophages from WT mice, at both time intervals evaluated. These findings identify TLR2 via MyD88 adaptor molecule as an essential signaling pathway regulating LD biogenesis induced by the venom sPLA₂ MT-III in macrophages. Considering that LD-laden macrophages constitute the foam cells seen at the sites of atherosclerotic lesion, in which levels of the sPLA₂s are increased, our present findings suggest that activation of TLR2/MyD88-mediated signaling pathway is likely to be an important mechanism that accounts for foam cell formation stimulated by group IIA sPLA₂s.

Requirement of TLR2 and/or MyD88 Signaling for MT-III-induced Perilipin-2 up-Regulation and Mobilization

Perilipin-2 has long been reported as a pivotal protein for neutral lipid accumulation that serves as scaffolding during LD formation in diverse cell types, including macrophages [50,51]. This protein is constitutively and ubiquitously expressed in macrophages as a major component of intracellular LDs [50,52–54]. Moreover, the expression of perilipin-2 can be up-regulated during inflammatory processes [51,55,56]. Consistent with these properties, perilipin-2 has been used as a marker of lipid loading and LD assembly in inflammatory cells [57]. Accumulating evidence indicates that activation of the Toll like receptors triggers foam cell formation and increase of perilipin-2 protein expression [49,58,59]. In macrophages, MT-III has been shown to up-regulate perilipin-2 protein expression and to trigger mobilization of constitutive perilipin-2 to form new LDs in macrophages [14]. On this basis, we assessed the involvement of TLR2 and MyD88 in perilipin-2 protein expression induced by MT-III in macrophages for 6 h. As demonstrated in Figure 3B, following MT-III stimulation of WT macrophages, there is a significant increase of perilipin-2 protein expression in comparison with RPMI-stimulated WT macrophages. This increased protein expression was observed in TLR2⁻/⁻ macrophages stimulated by MT-III when compared with WT macrophages. Conversely, MyD88⁻/⁻ macrophages stimulated by this sPLA₂ were unable to up-regulate perilipin-2 protein expression as compared to WT macrophages. These data indicate that perilipin-2 protein expression induced by MT-III is dependent on MyD88 pathway, but not on TLR2 activation. Next we evaluated the potential role of TLR2 and MyD88 signaling in subcellular mobilization of perilipin-2 induced by MT-III. As illustrated in Figure 4, WT macrophages stimulated...
by MT-III exhibited strong fluorescent staining (green) for perilipin-2, with a punctate cytoplasmic pattern, which was absent in RPMI-stimulated control cells. Fluorescent Nile Red-labeled LDs were also visualized after MT-III-induced stimulation and were virtually absent in non-stimulated WT macrophages. After stimulation with MT-III, cytoplasmic-stained perilipin-2 matched perfectly with Nile Red–marked neutral lipid inclusions. As expected, no significant staining was detected in WT control macrophages. However, this phenomenon was not observed in macrophages from TLR2−/− or MyD88−/− mice, demonstrating that perilipin-2 subcellular distribution induced by MT-III is dependent on TLR2 and MyD88 signaling pathway in a tight correlation with the regulation of MT-III-induced LD formation by TLR2/MyD88 pathway.

MT-III Releases Free Fatty Acids from Macrophages

To better understand the mechanisms underlying activation of TLR2 and MyD88 signaling by MT-III in macrophages, we analyzed the ability of this sPLA2 to generate free fatty acids, which are recognized as efficient agonists of TLRs, mainly TLR2 [25,28,29,60]. The total fatty acid profile was then analyzed in macrophages from TLR2−/− or MyD88−/− mice, demonstrating that perilipin-2 subcellular distribution induced by MT-III is dependent on TLR2 and MyD88 signaling pathway in a tight correlation with the regulation of MT-III-induced LD formation by TLR2/MyD88 pathway.

The data presented herein indicate a major role for TLR2 in MT-III-induced production of inflammatory mediators by macrophages, since the production of PGE2, PGD2 and PGJ2 induced by MT-III was abrogated in MyD88−/− macrophages stimulated by MT-III. However, the increment of PGD2 and PGJ2 induced by MT-III was not altered in MyD88−/− macrophages, suggesting that their synthesis is triggered through an adaptor molecule other than MyD88, in the present experimental condition. This is the first demonstration that a secreted group IIA PLA2 directly activates macrophages to release PGE2. Noteworthy, the present findings also evidence, for the first time, that the production of a resolutive mediator is regulated by the TLR2 pathway.

A previous report of our group demonstrated that, similarly to mammalian GIIA sPLA2s [70], MT-III up-regulates COX-2 protein expression, a critical enzyme for PGs production in macrophages [13]. We herein extended the understanding of this mechanism by showing that MT-III up-regulates COX-2 expression via TLR2 and MyD88 signaling pathways in macrophages, based on the inability of TLR2−/− and MyD88−/− macrophages to express COX-2 in response to MT-III stimulus. Taking these data into account, and considering results showing that MyD88 adaptor molecule is involved in MT-III-induced production of PGE2, but not PGD2 or PGJ2, it is suggested that COX-2 is the major PGE2 biosynthetic pathway, whereas production of PGD2 and PGJ2 may be associated to both COX-2 and COX-1 biosynthetic pathways. Consistent with this hypothesis, a previous report has shown the ability of MT-III to induce an increment in the activity of COX-1 along with expression of COX-2 in macrophages [13].

The ability of sPLA2s, including MT-III, to induce the release of cytokines has been previously demonstrated [12,71]. The data presented herein demonstrate that this sPLA2 induces the release of IL-10 and IL-1β in a process mediated by TLR2/MyD88 signaling pathway. These findings also bring additional evidence that engagement of TLR2/MyD88 signaling pathway coordinates both the acute and resolutive responses in macrophages upon stimulation by the sPLA2 MT-III. Furthermore, increased IL-10 biosynthesis, observed in MT-III-stimulated WT macrophages, suggests that in our experimental conditions this cytokine regulates the synthesis of PGE2 via TLR2/MyD88 pathway activation, as a tight regulation of PGE2 biosynthesis by IL-10 has been previously demonstrated in macrophages [62–64].

LDs are cytoplasmic inclusions found in numerous immune cells associated with inflammation [51,54,65], such as foam macrophages, which are major cells of atherosclerotic lesions [66]. We recently demonstrated that MT-III induces LDs formation, recruitment and increased expression of the LD scaffold protein perilipin-2 in macrophages [14]. The results obtained herein demonstrate, for the first time, that TLR2 and MyD88 are essential elements for LD formation induced by MT-III, since TLR2−/− and MyD88−/− macrophages failed to respond with increased numbers of LDs. These results are in agreement with previous reports by others showing that TLR2/MyD88 pathway is involved in LDs formation in leukocytes [47–49]. On the other hand, our data further demonstrate that TLR2 deletion does not affect the ability of MT-III to induce a significant increase of perilipin-2 protein expression, but inhibits its capacity to mobilize constitutive perilipin-2 in the cytosol, evidencing that although not signaling for up regulation of perilipin-2 expression, this receptor is engaged for its recruitment, triggering an important mechanism for LD formation. In contrast, MyD88 deleted cells blocked MT-III-induced expression and mobilization of perilipin-2, implying the participation of this adaptor molecule in this effect. Therefore,
activation of a TLR other than TLR2 is involved in MT-III-induced expression of perilipin-2. To our knowledge, this is the first demonstration of participation of TLR2 and MyD88 pathways in the mechanisms leading to LDs formation induced by group IIA sPLA2, and that MyD88 is a crucial adaptor molecule mediating perilipin-2 expression and mobilization induced by this class of enzymes. Experimental studies have previously demonstrated that TLRs, particularly TLR2 via MyD88-dependent pathway, have relevant roles in the differentiation of recruited monocytes into lipid-laden macrophages (foam cells), and ultimately to the development of atherosclerotic lesions [67,68]. Considering the reported increased expression of group IIA sPLA2α at the site of atherosclerotic lesions [9], our present findings may shed light on the early mechanisms involved in the ability of sPLA2s to induce formation of foam macrophages.

The mechanisms by which MT-III activates TLR2 were not presently investigated. It has been shown that a free fatty acid (FFA)-rich microenvironment leads to the activation of TLR2 [28,60]. Moreover, there are data demonstrating that products of cleavage of membrane phospholipids by sPLA2α, including saturated fatty acids, lysophosphatidylcholine and lysophosphatidylserine, are able to activate this receptor [60,72,73,74].

**Figure 4. TLR2 and MyD88 are essential for MT-III-induced perilipin-2 (PLIN2) subcellular distribution.** Wild Type (WT), TLR2 −/− or MyD88 −/− peritoneal macrophages were incubated with RPMI (control) or MT-III (0.4 μM) for 6 h and labeled for both lipid droplets (fluorescent Nile red) and anti-PLIN2 (FITC-conjugated immunocomplex). Merged image shows localization of PLIN2 to lipid droplets in WT macrophages. Cell nuclei were stained with propidium iodide. IgG control was included and showed negative stain. The micrographs are representative of at least three samples/experimental group.

doi:10.1371/journal.pone.0093741.g004
context, we herein demonstrate that MT-III reduced the levels of saturated FFA, such as palmitic and stearic acid, as well as monounsaturated and polyunsaturated fatty acids in macrophages. Decreased levels of both palmitic and oleic acids correlated with increased amounts of these fatty acids in the extracellular medium, indicating that they are released from macrophages upon the action of MT-III, thus allowing their interaction with surface membrane receptors. On this basis, we suggest that, in the present experimental conditions, saturated FFAs resulting from the catalytic action of MT-III on membrane phospholipids are autocrine ligands for TLR2, which then triggers an inflammatory program in macrophages, via pathways dependent on MyD88. However, participation of lysophospholipids in this mechanism cannot be ruled out. In support of our hypothesis, when catalytic action of MT-III on membrane phospholipids are autocrine ligands for TLR2, which then triggers an inflammatory program in macrophages, via pathways dependent on MyD88. However, participation of lysophospholipids in this mechanism cannot be ruled out. In support of our hypothesis, when catalytic activity of MT-III is inhibited, increments in LD formation are abrogated [14]. In addition, the involvement of TLR2 in the release of the cytokines IL-1β and IL-10 induced by minimally modified LDL in macrophages has been previously described [46]. In conclusion, we provide evidence of a critical role for TLR2 and MyD88 adaptor molecule in mediating sPLA2-induced inflammatory responses in macrophages. We have shown for the first time that the TLR2 and MyD88 adaptor molecule are involved in cellular and molecular inflammatory processes triggered by the venom sPLA2 MT-III in macrophages, that include the production of eicosanoids and cytokines and the formation of LDs, as well as an increased expression of COX-2 and perlipin-2 mobilization and expression. Interestingly, these findings indicate that TLR2, via MyD88 adaptor molecule, links sPLA2s with LD and foam cell formation. Moreover, we speculate that saturated free fatty acids released by MT-III enzyme activity from phospholipids in the macrophage membrane, are autocrinally recognized by TLR2, thereby initiating an inflammatory signaling cascade in macrophages. Altogether, these findings amplify the current knowledge on the mechanisms involved in the stimulatory effects of Group IIA sPLA2s enzymes involved.

Figure 5. MT-III affects macrophage fatty acid content causing the release of palmitic and oleic acids. (A) The profile of major fatty acids in peritoneal macrophages from WT mice stimulated with MT-III (0.4 μM) (gray bars) or RPMI (control) (open bars) for 6 h was determined by GC-MS after converting the glyceryl fatty acid into fatty acid methyl esters. (B) Peritoneal macrophages were incubated with 1 μM [14C]palmitic acid or (C) [14C] oleic acid for 18 h. Afterward, [14C]palmitic acid or [14C] oleic acid incorporation was measured in macrophages and their supernatants 6 h after stimulation with either MT-III or RPMI (control) as described in Materials and Methods. The ^14C radioactivity incorporated is expressed as a percentage of the radioactivity originally added to the cells. Results are expressed as means ± SEM from 3–6 animals. *p<0.05 as compared with the corresponding control.
