ABSTRACT

Acute lymphoblastic leukaemia (ALL) is the most frequent childhood cancer. Children usually present with signs of bone marrow failure like recurrent or prolonged fever, pallor, lethargy, bleeding tendencies, bone pain and others. Occasionally they may present with sign of infiltration of leukaemic cells into other organs such as testicular and central nervous system, rarely to the periorbital or orbital region. Similarly in relapse cases, they typically presented either in bone marrow, central nervous system relapse or testicular but rarely orbital involvement. Here we report the clinical case of a five-year-old boy who developed relapsed B-ALL, presented to us with unilateral right eye swelling without other clinical findings and absence of blast cells in the peripheral blood film as well as bone marrow aspirate specimen.

Keywords: Acute Lymphoblastic Leukaemia, Relapsed, Eye Swelling

Case report

The patient presented at the age of 1 year and 9 months old with four days history of fever, facial puffiness, and abdominal distension. He had pallor, generalized lymphadenopathy and hepatosplenomegaly. The initial full blood picture showed bicipotopenia with 47% circulating blast cells. The bone marrow aspirate (BMA), trephine biopsy and immunophenotyping confirmed presence of 51% blast cells with common B-ALL and an aberrant expression of CD13. His cerebrospinal fluid (CSF) analysis showed the

presence of blast cells. He was started on ALL BFM95 (moderate risk) due to elevated leukocyte count of 34.36 x 10⁹/l. Following the completion of the chemotherapy protocol after two and a half years, he was in remission with minimal residual disease detection level (<0.01%).

He presented again 4 months after completed his chemotherapy regimen with a month history of frontal headache and sudden onset of right eye swelling. There were right upper eyelid swelling and proptosis of the right orbit. The symptoms persisted (Figure 1) with progression into the periorbital area. There was no retro-orbital pain, no extraocular muscle palsies, diplopia, nystagmus or chemosis. The presentation did not appear consistent with an infectious aetiology.

After a few days in the ward, he developed status epilepticus requiring ventilation for cerebral protection. A computed tomography (CT) brain and magnetic resonance imaging (MRI) brain showed right extraconal mass measured about 2.6 x 1.5 x 2.4 cm (anteroposterior, width and cranial caudal) respectively with a deviation of the right optic nerve medially and infiltrated into the right cavernous sinus (Figure 2).

Repeated bone marrow aspirate and immunophenotyping a month later demonstrated evidence of early relapse of B-ALL. Thus, he was treated as relapsed B-ALL and started with (Standard 2) REZ BFM chemotherapy protocol.
Discussion

Several case reports have shown patients that have similar presentation to our patients [7, 8]. Both reported patients presented with an isolated periorbital swelling without local signs of infection. They were initially treated for infectious aetiologies until the bone marrow biopsy confirmed the diagnosis of ALL. The difference was these patients had orbital findings at the early presentation of the disease while unfortunately in our patient, the orbital symptoms were the early feature of the relapsed ALL.

In addition to leukaemia, many other pathologies that need to be excluded when the patient presents with unilateral proptosis or eye swelling. It can be due to solid tumour, infection or vascular malformations. Otherwise, it also can be divided into the osseous and non-osseous lesion [2]. Table 1 simplified the causes of unilateral eye swelling in children.

| Osseous | Non-osseous |
|---------|-------------|
| Dermoid cyst is the most common paediatric osseous tumour, fibrous dysplasia, juvenile ossifying fibroma, osteosarcoma, Langerhans cell histiocytosis and bony metastases from neuroblastoma | Rhabdomyosarcoma, vascular origin (capillary haemangioma, venous-lymphatic malformations) as well as infantile fibromatosis and nerve sheath tumours (optic nerve glioma) |

These showed to us that the presentation of unilateral periorbital swelling in a patient with history of leukaemia warrants a careful assessment in order not to miss important differential diagnosis especially early relapse. The dilemma occurs when bone marrow and CSF did not support relapse finding. The decision to perform an orbital biopsy does not come without a risk.

Conclusion

We described the clinical course of a five-year-old boy who presented with unilateral periorbital swelling as his first relapse symptoms of ALL. This is not a typical presentation of relapse leukaemia. Thus, this case brings enlightenment that periorbital oedema or swelling or proptosis must always be approached with thorough and broad differential as serious underlying causes may be present.

Conflicts of interest

I do not believe that there is a conflict of interest that could potentially be construed to affect the material contained in the manuscript that is being submitted to the journal.
