Thursday, October 3, 2019: 12:15 PM

Background. Splash and aerosolization from sink drains are a source of contamination, particularly by Gram-negative bacilli (GNB), in healthcare facilities. Neonatal Intensive Care Unit (NICU) outbreaks of infection due to GNB have been attributed to NICU sinks. Recent studies found that a dome-shaped drain cover placed in sinks in an adult ICU prevents spread of sink drain bacteria to the environment and hands of healthcare providers. Our NICU routinely performs weekly surveillance cultures of all endotracheal tubes (ETT) and has previously reported a correlation of ETT colonizing organisms with bacteria isolated from blood in late onset sepsis. Our objective was to determine whether the use of a drain cover in every sink in a level III 72 bed NICU could lead to a decrease in the isolation of GNB in the ETTs of hospitalized infants.

Methods. All 34 sink drains and basins in an open layout NICU were cultured. Drain covers were then installed and replaced on a routine basis. Weekly endotracheal tube cultures were performed for all intubated infants.

Results. Prior to implementation of drain covers, the most common GNBs cultured from ETTs were, in order, E. cloacae, Klebsiella spp., Acinetobacter baumannii and S. maltophilia. The most common organisms isolated from sinks were, in order, P. aeruginosa, Acinetobacter baumannii and S. maltophilia. An unusual species, Acinetobacter ursingii was cultured from one sink and endotracheal tubes. Before and after the implementation of drain covers, the median time to first isolation of a GNB was 14 and 17 days, respectively. Prior to draining cover implementation, there were 31 new GNB isolates during 700 ventilator days (rate of 44.3/1000 ventilator days) among ventilators with positive ETT cultures. Post drain cover implementation, there were 26 new GNB isolates during 900 ventilator days (rate of 28.9/1000 ventilator days). There was a shift in microbial species isolated from ETTs with Klebsiella spp. and S. marcescens predominating after implementation of drain covers.

Conclusion. The use of a novel drain cover in the sinks in a NICU can reduce the frequency of GNB colonizing the ETTs of patients and can lengthen the time to first positivity. Mitigating sinks as a reservoir for GNB may reduce the likelihood of these bacteria infecting a vulnerable population.

591. Mupirocin and Chlorhexidine Resistance in Staphylococcus aureus Isolated from Children in South Korea
Bi Na Kim, MD1; Hyun Mi Kang, MD1; Sun Hee Park, MD, PhD2; Joonhong Park, MD, PhD3; Jin Han Kang, MD, PhD4 and Jong Hyeon Kim, MD, PhD; 1College of Medicine, The Catholic University of Korea, Daejon, Daejon-jikhalsi, Republic of Korea; 2Division of Infectious Diseases, Department of Internal Medicine, College of Medicine, The Catholic University of Korea, Seoul, Korea, Daejon, Daejon-jikhalsi, Republic of Korea
Session: 64. HAI: Pediatric
Thursday, October 3, 2019: 12:15 PM

Background. Increasing prevalence of mupirocin-resistant Staphylococcus aureus have been reported, and chlorhexidine resistance has become an issue. This study aimed to investigate the prevalence of mupirocin and chlorhexidine resistance in both colonized and infection causing Staphylococcus aureus in children, and find factors associated with increased virulence.

Methods. Staphylococcus aureus, isolated from children <18 years old admitted at a single center, were collected prospectively from August 2017 to July 2018. The isolates underwent multicolumn sequence typing and were screened for genes causing chlorhexidine resistance (qacA/B), quaternary ammonium resistance (smr), mupirocin resist- ance (ileS mutation, Map A, MupB), and Pantone Valentine Leucocidin (pvl) toxin.

Results. During the study period, a total of 49 non-duplicate isolates were included, of which 69.4% (n = 34) were Methicillin-resistant Staphylococcus aureus (MRSA). Of the colonizers (n = 25), the most common sequence type was ST 72 (68.0%), whereas among pathogens (n = 24), ST 72 (29.2%) and ST 89 (29.2%) were most prevalent. Pathogens in this study caused abscess formation (n = 3), sepsis (n = 4), and primary infections such as cellulitis and emphysematous bullae (n = 17). Mupirocin resist- ance was found in 16.0% among colonizers vs. 45.8% among pathogens (P = 0.023). High-level mupirocin resistance was more common (n = 3/25, 12.0%) than low-level mupirocin resistance (n = 1/25, 4.0%) in colonizers, whereas, pathogens had similar rates of low-level (25.0%) and high-level (20.8%) mupirocin resistance. PVL toxin gene was more frequently found in colonizers than pathogens (64.0% vs. 33.3%, P = 0.032), and all isolates had quaternary ammonium resistance genes. Chlorhexidine resis- tance gene was found in only 3 MRSA isolates colonized in the nares of preterm infants. All were SCCmec type II, however, two were ST 72, spa type 11054, which had high-level mupirocin resistance and PVL toxin gene.

Conclusion. A PVL toxin gene-positive MRSA which had genes causing mupiroc- in and chlorhexidine resistance were found in the nasal carriage of preterm infants. These stains may be a source of MRSA eradication in hospital settings, using conven- tional methods of nasal mupirocin application and chlorhexidine bathing.

Thursday, October 3, 2019: 12:15 PM

Background. Published reports have raised concern that RNs spend less time in hospital rooms of patients requiring isolation precautions. Other patient-related factors including race/ethnicity, primary language, and socio-economic factors report- edly influence the mean time spent in the room by RNs and certified nursing assis- tants. The aim of this study was to assess the influence of patient isolation status on time spent in the room by RNs and CNAs to understand the reasons why these workers may be spending less time in the rooms of patients who require isolation.

Methods. RNs and CNAs routinely wore badges with infrared signal technology to monitor hand hygiene compliance, generating time-stamped data for room entries and exits, identified by user job category. Over a 30 day period, April 2016, RN and CNA time in the room was compared by patient characteristics including: length of stay, white yes/no, Hispanic yes/no, interpreter needed yes/no, and isolation status of contact-droplet, contact, or none. Mean minutes spent in the room for RNs and CNAs were evaluated with a random-effects linear model and gamma distribution.

Results. Admissions for 220 patients occurred in the 24 hours during the evalu- ation period with 186 RNs and 28 CNAs completing room entries and exits. The natural log of patient length of stay (hours) was significantly associated with increased RN and CNA minutes spent in the room (P < 0.001). Interpreter required was not associated with time in the room (P = 0.72), nor was race (P = 0.60), nor was Hispanic-ethnicity (P = 0.81). There was no significant association of minutes spent in time in the room for contact, contact-droplet, and no isolation (P = 0.92).

Conclusion. Data derived from infrared signal AHIMS badges can provide in- sight into RN and CNA care patterns. Isolation status and patient demographics were unrelated to mean RN and CNA time in the room. Patient length of stay was the only predictor of increased nursing time spent providing direct patient care. These results contrast with previous reports demonstrating fewer nursing interactions based on patient demographics or isolation.

593. Burden of Healthcare-Associated Infections among Hospitalized Infants within Community Hospitals
Ibukonoluwa C. Akinboyo, MD1; Rebecca R. Young, MS, MSc2; Michael J. Smith, MD, MSCE3; Becky A. Smith, MD4; Sarah S. Lewis, MD5 and Deverick J. Anderson, MD, MPH6; 1Duke University, Durham, North Carolina; 2Duke University Medical Center, Durham, North Carolina; 3Duke University Hospital, Durham, North Carolina; 4Duke University Medical Center, Durham, North Carolina; 5Duke University Hospital, Durham, North Carolina; 6Duke Center for Antimicrobial Stewardship and Infection Prevention, Durham, North Carolina
Session: 64. HAI: Pediatric
Thursday, October 3, 2019: 12:15 PM

Background. Healthcare-associated infections (HAI) remain the leading cause of morbidity and mortality among hospitalized children. Within community hospitals with limited infection prevention capacity, participation in an infection control net- work has led to significant decreases in device or procedure-related infections among adult patients. The impact of these interventions has not been assessed in pediatric patients admitted to community hospitals.

Methods. We conducted a retrospective cohort study to describe the burden of HAI among hospitalized infants (< 1 year old) within 53 community hospitals participating in the Duke Infection Control Outreach Network (DICON) from 2013–2018. We determined the frequency of device-related HAI, central line-associated bloodstream infections (CLABSI) and hospital-associated pneumonia or ventilator-associated events (HAP/VAEs) using National Healthcare Safety Network (NHSN) definitions; and the burden of HAIs among neonatal intensive care units (NICU) and non-NICU centers. The trend of HAI was analyzed with Spearman’s correlation.

Results. Thirty hospitals reported 150 HAI among 141 infants over the 6-year period. Median (IQR) time to infection was 10 (4, 20) days after admission. Hospitals with a NICU (15) reported more HAI (median 5, (IQR: 3, 12)) than hospitals without a NICU (median 2 (IQR: 1, 2)) (P = 0.031). CLABSI represented 35% of HAI, HAP/VAEs were 23% and CAUTI were 12%. There were no infections isolated from a single NICU patient for all HAI was Escherichia coli (22 HAI, 15%) which was also isolated in 39% of CAUTI. Methicillin-resistant and methicillin-susceptible Staphylococcus aureus (S. aureus) were the most commonly isolated organisms among CLABSI (17%) and HAP/VAEs (33%). Nine centers with ≥24 NICU and Central line (CL) use reported a median (IQR) rate of 1.2 (0.2, 4.0) CLABSI/s/1,000 central line days. There was no change in median CLABSI rate over time (P = 0.47), Figure 1.

Conclusion. CLABSI, most commonly caused by S. aureus, represented the majority of HAI reported in NICUs; the majority of infections within community hospitals participating in an infection control network. Further research into device utilization practices may inform future interventions to reduce HAI.
