substitutions previously reported to mediate ceftaroline resistance (Table 1). Two isolates (ASARM167 and A38) belonging to ST22 (epidemic MRSA-15) had an E239K substitution in PBP2a. ASARM167 was isolated from a patient with bacteraemia at Cambridge University Hospitals NHS Foundation Trust (CUH) in 2008 and A38 was isolated from a canine wound infection in 2006 treated in Wiltshire, south-west England. Phylogenetic analysis of these two isolates based on core genome SNPs placed them in different clades separated by >120 SNPs (data not shown), indicating that the E239K mutation arose independently in these two isolates. The third isolate (ASARM130) had the N146K substitution in PBP2a, belonged to ST241 (CC8) and was isolated from a patient with bacteraemia at CUH in 2007. This isolate was also noted to have an N204K substitution, which has not been reported previously in isolates with the N146K substitution.  

The effect of these PBP2a substitutions on the ceftaroline resistance phenotype was evaluated for these three isolates using the disc diffusion assay based on EUCAST guidelines and the Etest (bioMérieux, Lyon, France) according to the manufacturer’s instructions. Two isolates were susceptible and one was resistant to ceftaroline by disc diffusion, but all three isolates were susceptible by Etest (Table 1). Although isolates with the N146K substitution have been reported previously to have an MIC of 0.5 mg/L (susceptible), all previously reported isolates with E239K had an MIC of ≥2 mg/L (resistant). The lack of association between a resistant phenotype and the N146K substitution indicates that secondary chromosomal mutations are likely to be involved, as reported previously. The three study isolates were cultured before the clinical phenotype and the N146K substitution indicates that secondary chromosomal mutations are likely to be involved, as reported previously.

Sir,

Tetracycline can still be used for treatment of infections caused by *Acinetobacter baumannii* as tetracycline resistance is often caused by *tetA* (A) and *tetA* (B), which encode efflux pumps, and occasionally by *tet(M)*, which encodes a ribosomal protection protein. In addition, a novel determinant, *tet39* (*tetA*39-*tetR*39), was found in tetracycline-resistant *Acinetobacter* strains recovered from freshwater fish farms in Denmark and Thailand and from a clinical *Acinetobacter calcoaceticus/baumannii* complex isolate recovered from human urine in 1986. The *tetA*39 gene encodes an efflux pump that was reported to confer resistance to tetracycline but not minocycline.

In strains belonging to global clone 1 (GC1), the *tetA* gene is part of the AbaR resistance island while in GC2 isolates the *tetA* (B) gene is found in an AbGRI1 resistance island. However, there is little information about the tetracycline resistance determinants and their context in strains that do not belong to the two major global clones. Here, we have examined the cause of tetracycline resistance in RCH52, a clinical multiply antibiotic-resistant *A. baumannii* strain recovered prior to 2010 in a Queensland hospital.

RCH52 was found to be resistant to ampicillin, ceftazidime, ticarcillin/clavulanic acid, imipenem, meropenem, streptomycin, spectinomycin, sulphonamides, trimethoprim, kanamycin, gentamicin and tetracycline. The genome of RCH52 was sequenced using the Illumina HiSeq platform and assembled as described previously, generating 60 contigs. RCH52 was ST729 (Institut Pasteur scheme), a novel single locus variant of ST3 (*rpoB*4 in ST729 differs from *rpoB*3 in ST3 by a single base pair) and RCH52 therefore belongs to the European clone III. To the best of our knowledge this is the first report of the European clone III in Australia. ResFinder 2.1 (https://cge.cbs.dtu.dk/services/ResFinder/) was used to identify resistance genes, and RCH52 contains *aphA1b, aacC2, aadA1, floR, cmlA1, arr-2, sul1, sul2, dfrA14, oxa10, blatem, oxa23* (encoding a variant of OXA-23 differing by four amino acids) and the *tet39* determinant, accounting for the resistances observed. The *comM* gene is uninterrupted and ISAb1 was not found upstream of the *ampC* gene.

The *tet39* determinant was found on an 11 kb contig that was shown to be circular using PCR followed by sequencing. The plasmid carrying *tet39*, named pRCH52-1 (GenBank accession number KT346360; Figure 1), is 11146 bp. Plasmid DNA was

---

**Figure 1.** Linearized map of pRCH52-1 compared with other plasmids. (a) Comparison of the original *tet39* region found in pLUH5605 with the corresponding region found in pRCH52-1 and pAB11H8. (b) pRCH52-1 compared with the cryptic plasmids pAb-G7-1 and pD72-1 seen in GC1 and GC2 strains, respectively. Arrows indicate the extent and direction of genes and ORFs. The *tetA* gene and *tetR* genes of *tet39* are shown in red and rep genes are coloured blue. The *tonB* gene encodes a TonB-dependent transporter homologue. The green box indicates ISAb125 and the arrow inside represents the transposase gene. The extents of regions with significant DNA identities are shown in grey and red numbers represent DNA identities. A scale bar is also shown. The picture is drawn to scale from the following GenBank entries: pRCH52-1, GenBank accession number KT346360; pAb-G7-1, GenBank accession number KJ586856; pD72-1, GenBank accession number KM051986; pLUH5605, GenBank accession number AY743590; and pAB11H8, GenBank accession number ANNC01000048. This figure appears in colour in the online version of JAC and in black and white in the print version of JAC.
isolated and electroporated into A. baumannii ATCC 17978, which is tetracycline susceptible. Transformants were selected on L-agar supplemented with 20 mg/L tetracycline (transformation frequency $= 4.5 \times 10^7$ transformants/µg of DNA). None of the transformants grew on L-agar containing other antibiotics that RCH52 was resistant to, indicating that only the tetracycline resistance had transferred into the recipient cells. Primers tet39-F (5’-GCAGCTAATGCCCATACCAT-3’) and tet39-R (5’-GCCCTTTTGCCGTGTTACCAT-3’) were designed to amplify a 219 bp internal fragment of the tetA39 gene. This PCR generated the expected product for all of the transformants tested. Although it was reported that tet39 does not confer resistance to minocycline, transformants tested here exhibited reduced susceptibility to minocycline, with inhibition zone diameters of 18 mm compared with 26 mm for ATCC 17978.

The original study showed that tet39 was located on plasmids but only a 3727 bp fragment of one plasmid (named pLUH5605) was sequenced (GenBank accession number AY741590). This sequence, the only complete tet39 sequence found in the GenBank non-redundant database, includes tetA39, tetR39 and two ORFs (Figure 1a), one of which encodes a replication initiation protein. Only 2360 bp of the pLUH5605 sequence was present in prior RCH52-1 (Figure 1a). To explore the distribution of the tet39 determinant in Acinetobacter strains, the whole genome sequence database of NCBI was explored using the sequences of pRCH52-1 and pLUH5605. Twenty-one Acinetobacter strains belonging to different species were found to contain tet39 (Table S1, available as Supplementary data at JAC Online). However, the tet39 region appears to be in different contexts in all but one A. baumannii strain, AB1H8 (GenBank accession number ANNC010000048). AB1H8 appears to include a plasmid that contains a Rep that is 97% identical in terms of amino acids to the pLUH5605 RepA (Figure 1a). Hence, discrete boundaries surrounding tet39 were not found.

pRCH52-1 encodes a replication initiation protein Rep that belongs to the Rep_3 superfamily (pfam01051) and differs from the Rep found in pLUH5605 by 43%. The pRCH52-1 Rep is identical to the Rep protein found in a strain belonging to the A. calcoaceticus/baumannii complex (NCBI Reference Sequence number WP_0008485850). Thereafter, the closest Rep is RepAc7 (GenBank accession number GU978996), with 96% amino acid identity.

pRCH52-1 also encodes a TonB-dependent transporter homologue. These outer membrane proteins bind and transport siderophores, vitamin B$_12$, nickel complexes and carbohydrates. This gene is also present in several cryptic plasmids of A. baumannii including pAb-G7-1 and pD72-1 from GC1 and GC2 strains, respectively. However, the amino acid sequence of Rep encoded by pRCH52-1 differs from those in pAb-G7-1 (GenBank accession number KJS86856) and pD72-1 (GenBank accession number KM051986) by 24% and 21%, indicating that the tonB gene, which is a potential virulence determinent, is widely distributed.

The tet39 determinant is widespread in Acinetobacter species. It has also been found in other species of Gram-negative and Gram-positive bacteria recovered from a polluted Nigerian river. Its location on plasmids in clinical isolates would facilitate the spread of tetracycline resistance amongst Acinetobacter strains, leading to further restriction of treatment options.

Acknowledgements

We thank Dr Mohammad Katouli for sending us RCH52. We also thank the team of curators of the Institut Pasteur Acinetobacter MLST system for curating the data and making them publicly available at http://pubmlst.org/abauumannii/.
