LOW MACH NUMBER LIMIT OF STEADY EULER FLOWS IN
MULTI-DIMENSIONAL NOZZLES

MINGJIE LI, TIAN-YI WANG, AND WEI XIANG

Abstract. In this paper, we consider the steady irrotational Euler flows in multi-
dimensional nozzles. The first rigorous proof on the existence and uniqueness of the
incompressible flow is provided. Then, we justify the corresponding low Mach number
limit, which is the first result of the low Mach number limit on the steady Euler flows.
We establish several uniform estimates, which does not depend on the Mach number, to
validate the convergence of the compressible flow with extra force to the corresponding
incompressible flow, which is free from the extra force effect, as the Mach number goes
to zero. The limit is on the Hölder space and is unique. Moreover, the convergence rate
is of order $\varepsilon^2$, which is higher than the ones in the previous results on the low Mach
number limit for the unsteady flow.

1. Introduction

Incompressible and compressible Euler equations are fundamental equations in fluid
dynamics, which describe the motion of two different objects, for example, water and
gas. As one of the important topic in the mathematical theory of fluid dynamics, the
incompressible limit is devoted to building a bridge to fill the gap between those two
different type of fluids by determining in which sense that the compressible flows tend
to the incompressible ones as the compressibility parameter tends to zero.

One of the typical system to describe compressible flow is the steady homentropic
Euler equations. It reads

\[
\begin{align*}
\text{div}(\rho u) &= 0, \\
\text{div}(\rho u \otimes u) + \nabla p &= \rho F, \\
\end{align*}
\]

where $x = (x_1, \cdots, x_n) \in \mathbb{R}^n$, for $n \geq 2$, $u = (u_1, \cdots, u_n) \in \mathbb{R}^n$ is the fluid velocity, while
\( \rho, p, \) and \( F \) represent the density, pressure, and extra force respectively. The pressure is
a function of density with:

\[
p := \frac{\tilde{p}(\rho) - \tilde{p}(1)}{\varepsilon^2},
\]

where $\varepsilon > 0$ is the compressibility parameter as introduced in [36]. As the homentropic
flow, we require

\[
\tilde{p}'(\rho) > 0, \quad 2\tilde{p}'(\rho) + \rho \tilde{p}''(\rho) > 0 \quad \text{for} \ \rho > 0.
\]

We remark that condition (1.3) holds for the flows which satisfy the polytropic gases
that $\tilde{p} = \rho^\gamma$ with $\gamma > 1$, and the isothermal flows that $\tilde{p} = \rho$. The sound speed of the
flow is
\[ c := \sqrt{p'(\rho)} = \sqrt{\tilde{p}'(\rho)}, \]
and the Mach number is defined as
\[ M := \frac{|u|}{c} = \frac{\varepsilon |u|}{\sqrt{\tilde{p}'(\rho)}}, \]
where
\[ |u| := \left( \sum_{i=1}^{n} u_i^2 \right)^{1/2} \]
is the flow speed. The flow is subsonic when \( M < 1 \), sonic when \( M = 1 \), and supersonic when \( M > 1 \).

Generally speaking, there are two processes for deriving the incompressible fluid models from the respective compressible ones: one is that the compressible parameter \( \varepsilon \) goes to zero, which is called as the low Mach number limit; and the other one is that the adiabatic exponent \( \gamma \) goes to the infinity with the pressure defined as \( p = \rho^\gamma \), see \([9, 32]\).

The first theory of the low Mach number limit is due to Janzen and Rayleigh (see \([35, \text{Sect. 47}]\), \([39]\)), in which they are concerned with the steady irrotational flow. Their method of the expansion of solutions in power with respect to the Mach number was applied both as a computational tool and as a tool for the proof of existence of solutions. Klainerman and Majda \([28, 29]\) proved the convergence of compressible flow to the incompressible flow by directly deriving estimates of solutions of the partial differential equations in the scaled form (also see Ebin \([17]\)). In particular, they established the incompressible limit of smooth local solutions of the Euler equations (and the Navier-Stokes equations) for compressible fluids with well-prepared initial data, i.e., some smallness assumption on the divergence of initial velocity. By using the fast decay property of acoustic waves, Ukai \([38]\) verified the low Mach number limit for the general data. The exterior domain cases were considered in \([25]\). The major breakthrough on the general initial data is due to Métivier and Schochet \([33]\), in which they proved the low Mach number limit of the full Euler equations in the whole space by an elegant convergence lemma on acoustic waves. Later, Alazard \([1]\) extended the result to the exterior domain problem. For the one dimensional Euler equations, the low Mach number limit has been proved under the \( B.V. \) space in \([7]\). For other related fluid models and problems, see \([5, 11, 22, 26, 27, 30, 31, 33, 34, 36]\) and the references therein.

One of classical problems on the steady flows is the infinitely long nozzle problem. Let \( \Omega \subset \mathbb{R}^n \) be an infinitely long nozzle, which is homomorphism on the unit cylinder \( C = B(0,1) \times \mathbb{R} \) in \( \mathbb{R}^n \). The compressible fluid fills in the region \( \Omega \). At the boundary \( \partial \Omega \), the flow satisfies the slip boundary condition:
\[ u \cdot n = 0 \quad \text{on} \ \partial \Omega, \quad (1.4) \]
where \( n \) is the unit outward normal to the region \( \Omega \). Due to \([1.1]\) and \([1.4]\), one can obtain the fixed mass flux property: on the arbitrary cross section of the nozzle \( S_0 \)
\[ \int_{S_0} l \cdot \rho u ds =: m, \quad (1.5) \]
where \( l \) is the unit outer normal of the domain \( S_0 \). \( m \) is called the mass flux. See Figure \([1.1]\).
Formally, if $|u|$ is bounded and $\sqrt{\tilde{p}'(\rho)}$ does not vanish, $\varepsilon$ is the leading term of Mach number $M$. For this reason, the limit $\varepsilon \to 0$ is called the low Mach number limit\cite{28,29}. So, for the low Mach number limit, one should start from the case with sufficiently small Mach number, in which the flow is subsonic.

For the compressible flow, the mathematical theory on global subsonic flow in an infinitely long nozzle of various cross-section was formulated by Bers \cite{4} in 1958. Then the first rigorous proof for the irrotational flow was achieved by Xie and Xin \cite{40} by introducing the stream function. Later, they extended it to the 3D axis-asymmetric case in \cite{41}. The theorem for general infinitely long nozzle in $\mathbb{R}^n, n \geq 2$ was completed in Du-Xin-Yan \cite{15}, while the result was extended in \cite{20} to the extra force case. Besides the infinitely long nozzle problem, we also would like to mention the study of the other classical problem: the airfoil problem. Shiffman \cite{37}, Bers \cite{2,3}, and Finn-Gilbarg \cite{18} considered the two-dimensional irrotational subsonic flow. Finn and Gilbarg \cite{19} got the first result for three-dimensional subsonic flow past an obstacle under some restrictions on the Mach number. Then Dong \cite{13} and Dong-Ou \cite{14} extended these results to the case when Mach number $M < 1$ for arbitrarily dimensional case, while the case with conservative force effect was considered in \cite{21}. The respective subsonic-sonic flow was considered in \cite{24}. For the rotational subsonic flows, one can refer \cite{6,8,9,10,12,16,42}.

The expected corresponding homogeneous incompressible Euler equations as $\varepsilon \to 0$ are written as:

$$\begin{align*}
\text{div} \ u &= 0, \\
\text{div} (u \otimes u) + \nabla p &= F,
\end{align*}$$

(1.6)

where $u = (u_1, \cdots, u_n)$ and $p$ represents the velocity and pressure, respectively, while density $\rho \equiv 1$.

For the problem of the incompressible flow in an infinitely long nozzle, the flow also satisfies the slip boundary condition \cite{14}. Furthermore, from (1.6)$_1$, the fixed mass flux property \cite{15} holds with $\rho \equiv 1$.

As far as we know, up to now there is no mathematical result on the multidimensional incompressible flow in an infinitely long nozzle. Hence, we need to develop the methods to obtain the first results on the multidimensional incompressible flow in an infinitely long nozzle.
long nozzle. We remark, unlike the airfoil problem, the solutions of infinitely long nozzle problem are not expected to decay to the given states in general, which means the variational approach could not applied directly. So we need to introduce approximate problems for both the incompressible and compressible case, and then to show the localized uniform estimates such as the average lemma and the higher order estimates which do not depend on the Mach number, which is a singular parameter in the low Mach number limit. All the uniform estimates are new. Moreover, to avoid the singularity arising from the sufficiently small Mach number, we need to introduce the elliptic cut-off carefully, which is different from the ones in \cite{15,20}.

The rest of this paper is organized as follows. In Section 2, we formulate the problems mathematically and state the main theorems. Next, we introduce approximate problems and apply the variational approach to solve them in Section 3. In Section 4, uniform estimates and then the existence of modified flows are proven. Section 5 prove the uniqueness of modified flows, and complete the existence and uniqueness of the incompressible flow (Theorem 2.1). Finally, in Section 6, we complete the proof of the low Mach number limit (Theorem 2.2).

2. Formulation of the problem and main theorems

In this section we will formulate the problem concerned mathematically and introduce the main theorems of this paper.

First, we will give the basic assumptions on the multidimensional nozzle domain $\Omega$: there exists an invertible $C^{2,\alpha}$ map $T : \bar{\Omega} \to \bar{C} : x \to y$ which satisfies that

$$T(\partial \Omega) = \partial \bar{C},$$

$$\text{For any } k \in \mathbb{R}, \; T(\Omega \cap \{x_n = k\}) = B(0,1) \times \{y_n = k\},$$

$$\|T\|_{C^{2,\alpha}} + \|T^{-1}\|_{C^{2,\alpha}} \leq K < \infty,$$

(2.1)

where $K$ is a uniform constant, $\bar{C} = B(0,1) \times (-\infty, +\infty)$ is the cylinder in $\mathbb{R}^n$ with $B(0,1)$ being the unit ball in $\mathbb{R}^{n-1}$ centering at the origin, $x_n$ is the axial coordinate and $x' = (x_1, \ldots, x_{n-1}) \in \mathbb{R}^{n-1}$.

Remark 2.1. It is noticeable that there is no asymptotic restriction on $T$ as $x_n \to \pm \infty$, which implies $T$ could even be periodic respect to $x_n$.

For both the incompressible flow and the compressible flow, the boundary condition (1.4) and mass flux condition (1.5) hold.

Now, for any given mass flux $m$, we can introduce the problem in the multidimensional infinitely long nozzle mathematically for both the incompressible and compressible cases.

Problem ($m$). Let $n \geq 2$. Find functions $(\rho, u, p)$, which satisfies (1.1) or (1.6), with slip boundary condition (1.4) and mass flux condition (1.5), with

Then we will study Problem ($m$) for the incompressible and compressible cases separately.

2.1. Problem ($m$) for the incompressible case. Let us consider the incompressible case first. The steady irrotational incompressible Euler flow is governed by the following
LOW MACH NUMBER LIMIT OF STEADY EULER FLOWS IN MULTI-DIMENSIONAL NOZZLES

5

equations:
\[
\begin{align*}
\text{div } \bar{u} &= 0, \\
\text{div } (\bar{u} \otimes \bar{u}) + \nabla \bar{p} &= F, \\
curl \bar{u} &= 0.
\end{align*}
\] (2.2)

Here, the conservative force $F$ can be written as $F = \nabla \phi$. By (2.2), we have the Bernoulli law for the incompressible irrotational case that:
\[
\nabla \left( \frac{|\bar{u}|^2}{2} + \bar{p} - \phi \right) = 0,
\] (2.3)
which equals to:
\[
\bar{p} = \phi - \frac{|\bar{u}|^2}{2}
\] (2.4)
up to a constant.

Now we can introduce the following theorem for the incompressible case.

**Theorem 2.1.** For any fixed $m > 0$, there exists a unique solution $(\bar{\rho} \equiv 1, \bar{u}, \bar{p})$ of Problem (m) corresponding to equations (2.2), with $\bar{u} \in (C^{1,\alpha}(\Omega))^n$. Moreover, suppose $\phi \in L^\infty(\Omega)$ and $\nabla \phi \in L^q_{\text{loc}}(\Omega)$ for $q > n$. Then $\bar{p} \in C^{\alpha}(\Omega)$.

We remark that for the incompressible case, the velocity $\bar{u}$ is solved by solving the potential function $\bar{\phi}$, which does not depend on $\phi$. It is different from the compressible case.

2.2. Problem (m) for the compressible case and the low Mach number limit.

Now let us consider Problem (m) for the compressible case and the low Mach number limit. The irrotational compressible Euler flow with low Mach number is governed by the following equations
\[
\begin{align*}
\text{div } (\rho^\varepsilon \bar{u}^\varepsilon) &= 0, \\
\text{div } (\rho^\varepsilon \bar{u}^\varepsilon \otimes \bar{u}^\varepsilon) + \nabla p^\varepsilon &= \rho^\varepsilon F, \\
curl \bar{u}^\varepsilon &= 0,
\end{align*}
\] (2.6)
where the conservative force $F = \nabla \phi$ and $p^\varepsilon = p^{(\varepsilon)}(\rho^\varepsilon) = \bar{p}(\rho^\varepsilon) - \frac{\bar{p}(1) - \bar{p}(0)}{\varepsilon^2}$. The Mach number is defined as $M^\varepsilon = \frac{|\bar{u}|}{\sqrt{(p^{(\varepsilon)})'(\rho^\varepsilon)}} = \frac{\varepsilon |\bar{u}|}{\sqrt{\bar{p}'(\rho^\varepsilon)}}$.

By (2.6), we have the following Bernoulli law that
\[
\nabla \left( \frac{|\bar{u}^\varepsilon|^2}{2} + \int_1^{\rho^\varepsilon} \frac{p^{(\varepsilon)}(s)'(s)}{s} ds - \phi \right) = 0.
\] (2.7)
which is equivalent to
\[
\frac{|\bar{u}^\varepsilon|^2}{2} + \int_1^{\rho^\varepsilon} \frac{p^{(\varepsilon)}(s)'(s)}{s} ds = \phi,
\] (2.8)
up to a constant. Here, without loss of generality, we assume $0 \leq \phi \leq \phi^\ast$. Moreover, let us introduce the rescaled enthalpy function $\tilde{h}$, which satisfies:
\[
\tilde{h}'(\rho) = \frac{\bar{p}'(\rho)}{\rho}.
\]
Then, (2.8) becomes
\[
\frac{|u^\varepsilon|^2}{2} + h^\varepsilon(\rho^\varepsilon) - h^\varepsilon(1) = \phi, \tag{2.9}
\]
where \(h^\varepsilon(\rho) = \varepsilon^{-2} \tilde{h}(\rho)\). By (1.3), we can see that \(\tilde{h}(\rho)\) is a strictly increasing function with respect to \(\rho\), so does \(h^\varepsilon(\rho^\varepsilon)\).

Let
\[
\tilde{H}(\rho) := \frac{\tilde{p}'(\rho)}{2} + \tilde{h}(\rho).
\]

Then for each fixed \(\varepsilon\), we can introduce the critical density \(\rho^\varepsilon_{cr}\) which satisfies that
\[
\frac{1}{\varepsilon^2} \tilde{H}(\rho^\varepsilon_{cr}) = \phi + \frac{1}{\varepsilon^2} \tilde{h}(1). \tag{2.10}
\]

So
\[
\rho^\varepsilon_{cr}(\phi) = \tilde{H}^{-1} \left( \tilde{h}(1) + \varepsilon^2 \phi \right) \tag{2.11}
\]
and the critical speed is
\[
q^\varepsilon_{cr}(\phi) = \frac{1}{\varepsilon} \sqrt{\tilde{p}' \circ \tilde{H}^{-1} \left( \tilde{h}(1) + \varepsilon^2 \phi \right)}. \tag{2.12}
\]

Obviously, the critical speed \(q^\varepsilon_{cr}(\phi)\) will go to the infinity as \(\varepsilon\) goes to zero.

It is easy to see that \(|u^\varepsilon| < q^\varepsilon_{cr}(\phi)\) holds if and only if the flow is subsonic, \(i.e., M^\varepsilon(\phi) < 1\). Similarly, for each 0 < \(\theta < 1\), there exists \(q^\theta_{cr}(\phi)\) such that \(|u^\varepsilon| < q^\theta_{cr}(\phi)\) holds if and only if \(M^\varepsilon(\phi) \leq \theta\). Moreover, \(q^\theta_{cr}(\phi)\) is monotonically increasing with respect to \(\theta \in (0, 1)\). In addition, for \(\varepsilon > 0\), both \(q^\varepsilon_{cr}(\phi)\) and \(q^\theta_{cr}(\phi)\) are uniformly bounded with respect to \(\varepsilon\). For the subsonic flow, density \(\rho^\varepsilon\) can be represented as a function of \(|u^\varepsilon|^2\), \(i.e.,\)
\[
\rho^\varepsilon = \rho^\varepsilon(|u^\varepsilon|^2, \phi) = \tilde{h}^{-1} \left( \frac{\varepsilon^2 (2\phi - |u^\varepsilon|^2)}{2} + \tilde{h}(1) \right). \tag{2.13}
\]

For any fixed 0 < \(\varepsilon < 1\), when the flow is subsonic, it holds that
\[
\tilde{H}^{-1} \circ \tilde{h}(1) < \tilde{h}^{-1} \left( \tilde{h}(1) + \varepsilon^2 \phi \right) = \rho^\varepsilon_{cr} \leq \rho^\varepsilon(|u^\varepsilon|^2, \phi) \leq \tilde{h}^{-1} \left( \varepsilon^2 \phi + \tilde{h}(1) \right) < \tilde{h}^{-1} \left( \phi^* + \tilde{h}(1) \right).
\]

Finally, the low Mach number limit is the limit process when \(\varepsilon \to 0\). For the limit, we expect the compressible Euler flow will converge to the corresponding incompressible Euler flow. Actually, we have the following result which is the main theorem of the paper on Problem (m) for the compressible case and the low Mach number limit.

**Theorem 2.2.** Suppose (2.5) holds. For any fixed \(m > 0\), there exists constant \(\varepsilon_c\) such that when 0 < \(\varepsilon < \varepsilon_c\) there exists a unique solution \((\rho^\varepsilon, u^\varepsilon, p^\varepsilon) \in (C^0(\Omega))^n + 2\) of Problem (m) corresponding to equations (2.6) with \(M^\varepsilon < 1\). \(M^\varepsilon\) varies on (0, 1) as \(\varepsilon\) varies on (0, \(\varepsilon_c\)). Furthermore, as \(\varepsilon \to 0\), we have that
\[
\rho^\varepsilon = 1 + O(\varepsilon^2), \quad u^\varepsilon = \bar{u} + O(\varepsilon^2), \quad \nabla p^\varepsilon = \nabla \bar{p} + O(\varepsilon^2), \quad M^\varepsilon = O(\varepsilon) \tag{2.14}
\]

where \((1, \bar{u}, \bar{p})\) is the classical solution of Problem (m) corresponding to equations (2.2) obtained in Theorem 2.1.

**Remark 2.2.** It is noticeable that the condition (2.5) on \(\nabla \phi\) is local and without requirement on the decay behaviour at the infinity. In fact, for the infinitely long nozzle problem, the far field behaviour of flow can be treated by a quasi-one-dimensional problem, where the key point is the local average estimate.
Remark 2.3. It is easy to check the gravity:

\[ \phi = gx_i \]

for \( i = 1, \ldots, n - 1 \), satisfying the conditions (2.5) on \( \phi \). It can also be applied to the electric field.

Remark 2.4. In Theorem 2.2, the regularity of \((\rho, u, p)\) is restricted by the regularity of \( \phi \). One can lift the regularity of \( u \) and \( \rho \) by imposing higher regularity conditions on \( \phi \).

3. Approximate Problems and Variational Approach

Unlike the airfoil problem in [14], the asymptotic behaviours of the flow at the inlet and the outlet are different, in order to employ the variational approach, we also need to construct a series of truncated problems in bounded domains to approximate the Problem I1\((m)\) and Problem C1 \((m)\) which are introduced later. For \( L > 0 \), let

\[ \Omega_L = \{ x \in \Omega \mid |x_n| < L \}, \quad S_L^\pm = \Omega \cap \{ x_n = \pm L \}. \]  

(3.1)

Let \( H_L \) is a Hilbert space under \( H^1\)-norm such that

\[ H_L = \{ \varphi \in H^1(\Omega_L) : \varphi|_{S_L^\pm} = 0 \}. \]  

(3.2)

In this section, we will introduce the approximate problems of Problem \((m)\) to the incompressible case and the compressible case, and then obtain the existence of the solutions of the approximate problems by the variational approach.

3.1. Incompressible potential flow. Let us consider the incompressible case first. By (2.2)\(_3\), we can introduce the velocity potential \( \bar{\varphi} \) for the incompressible case that

\[ \nabla \bar{\varphi} = \bar{u}. \]  

(3.3)

Then, Problem \((m)\) for the incompressible case becomes:

**Problem I1 \((m)\).** Let \( n \geq 2 \). Find function \( \bar{\varphi} \) such that

\[
\begin{cases}
\Delta \bar{\varphi} = 0, & x \in \Omega, \\
\frac{\partial \bar{\varphi}}{\partial n} = 0, & x \in \partial \Omega, \\
\int_{S_0} \frac{\partial \bar{\varphi}}{\partial l} ds = m,
\end{cases}
\]  

(3.4)

where \( S_0 \) is any arbitrary cross section of the nozzle, and \( n \) and \( l \) are the unit outer normals of the nozzle wall \( \partial \Omega \) and \( S_0 \) respectively.

As said before, we will truncate the domain to introduce the approximated problems of Problem I1 \((m)\) in \( \Omega_L \) for \( L > 0 \). More precisely, Let us consider the following truncated problem for the incompressible flow that
Problem I2 \((m, L)\): Find a function \(\bar{\phi}_L\) such that,
\[
\begin{align*}
\Delta \bar{\phi}_L &= 0, \quad x \in \Omega_L, \\
\frac{\partial \bar{\phi}_L}{\partial n} &= 0, \quad \partial \Omega \cap \partial \Omega_L, \\
\frac{\partial \bar{\phi}_L}{\partial x_n} &= \frac{m}{|S^+_L|}, \quad \text{on } S^+_L \\
\bar{\phi}_L &= 0, \quad \text{on } S^-_L.
\end{align*}
\]
\[\tag{3.5}\]
Here \(|S^+_L|\) denotes the area of the cross section \(S^+_L\). We remark that boundary condition \((3.5)_3\) on \(S^+_L\) implies that the mass flux of the flow is \(m\).

Now we can introduce the variational approach to solve Problem I2 \((m, L)\).

Let functional \(J(\varphi)\) on \(H_L\) be defined as
\[
J(\varphi) = \frac{1}{2} \int_{\Omega_L} |\nabla \varphi|^2 dx - \frac{m}{|S^+_L|} \int_{S^+_L} \varphi dx',
\]
where \(x' = (x_1, x_2, \ldots, x_{n-1})\). Then in order to show the existence of solutions of Problem I2 \((m, L)\), we will solve the following variational problem:

Problem I3 \((m, L)\): Find a minimizer \(\bar{\phi}_L \in H_L\) such that
\[
J(\bar{\phi}_L) = \min_{\varphi \in H_L} J(\varphi).
\]
\[\tag{3.7}\]
For the minimizer of Problem I3 \((m, L)\), we have the following remark.

Remark 3.1. The minimizer of Problem I3 \((m, L)\) is a solution of Problem I2 \((m, L)\).

Proof. We only need to show that equation \((3.5)\) is the Euler-Lagrange equation of the variation problem. For any \(t \in \mathbb{R}^+\) and for any \(\varphi \in H_L\) and \(\eta \in H_L\), it is easy to know that \(\varphi + t\eta \in H_L\), so
\[
J(\varphi + t\eta) - J(\varphi) = \frac{1}{2} \int_{\Omega_L} (|\nabla \varphi + t\nabla \eta|^2 - |\nabla \varphi|^2) dx - \frac{m}{|S^+_L|} \int_{S^+_L} \eta dx'.
\]
Hence
\[
\lim \inf_{t \to 0^+} \frac{1}{t} (J(\varphi + t\eta) - J(\varphi)) = \int_{\Omega_L} \nabla \varphi \cdot \nabla \eta dx - \frac{m}{|S^+_L|} \int_{S^+_L} \eta dx'.
\]
If \(\varphi\) is the minimizer, then for any \(\eta \in H_L\), we have that
\[
J(\varphi + t\eta) - J(\varphi) \geq 0 \quad \text{and} \quad J(\varphi - t\eta) - J(\varphi) \geq 0.
\]
Therefore, for any \(\eta \in H_L\),
\[
\int_{\Omega_L} \nabla \varphi \cdot \nabla \eta dx - \frac{m}{|S^+_L|} \int_{S^+_L} \eta dx' = 0.
\]
It means that \(\varphi\) is the solution of Problem I2 \((m, L)\). \(\square\)

Therefore, in order to show the existence of solutions of Problem I2 \((m, L)\), we only need to show the existence of a minimizer of Problem I3 \((m, L)\).

For Problem I3 \((m, L)\), we have the following theorem:
Theorem 3.1. **Problem I3** \((m, L)\) admits a unique minimizer \(\bar{\varphi}_L \in H_L\). Moreover, it holds that

\[
\frac{1}{|\Omega_L|} \int_{\Omega_L} |\nabla \varphi_L|^2 dx \leq C m^2,
\]

(3.10)

where constant \(C\) does not depend on \(L\).

**Proof.** We divide the proof into four steps.

**Step 1.** \(J(\varphi)\) is coercive in \(H_L\). For any \(\varphi \in H_L\), we know that \(\varphi|_{S_L^+} = 0\) by the definition. So by the Hölder inequality,

\[
\left| \int_{S_L^+} \varphi dx' \right| = \int_{S_L^+} \int_{-L}^L \frac{\partial \varphi}{\partial x_n} dx_n dx' \leq C |\Omega_L|^{\frac{1}{2}} \|\nabla \varphi\|_{L^2}
\]

(3.11)

By the Cauchy inequality,

\[
J(\varphi) = \frac{1}{2} \int_{\Omega_L} |\nabla \varphi|^2 dx - \frac{m}{|S_L^+|} \int_{S_L^+} \varphi dx' \geq \frac{1}{4} \|\nabla \varphi\|^2_{L^2} - 2C(m, |S_L^+|, |\Omega_L|),
\]

which implies \(J(\varphi)\) is coercive.

**Step 2.** The existence of the minimizer \(\bar{\varphi}_L \in H_L\). Let \(\{\varphi_{L,n}\} \subset H_L\) be a minimizer sequence such that, as \(n \to \infty\)

\[
J(\varphi_{L,n}) \to \alpha = \inf_{\varphi \in H_L} J(\varphi) > -\infty.
\]

Since \(J(\varphi)\) is coercive in \(H_L\),

\[
\int_{\Omega_L} |\nabla \varphi_{L,n}|^2 dx \leq 4J(\varphi_{L,n}) + 8C(m, |S_L^+|, |\Omega_L|) \leq 4J(0) + 8C(m, |S_L^+|, |\Omega_L|) = 8C(m, |S_L^+|, |\Omega_L|).
\]

Therefore, there exists a subsequence, still denoted by \(\{\varphi_{L,n}\}\), which converges weakly to a function \(\bar{\varphi}_L \in H_L\). And, by the lower semi-continuity, it holds that

\[
\|\nabla \bar{\varphi}_L\|^2_{L^2} \leq \liminf_{n \to \infty} \int_{\Omega_L} |\nabla \varphi_{L,n}|^2 dx \leq 4C(m, |S_L^+|, |\Omega_L|).
\]

(3.12)

On the other hand, similar to the proof of (3.11), we have

\[
\int_{S_L^+} (\bar{\varphi}_{L,n} - \bar{\varphi}_L)^2 dx' \leq C(\Omega_L) \left( \int_{\Omega_L} |\varphi_{L,n} - \varphi_L|^2 dx \right)^{\frac{1}{2}} \left( \int_{\Omega_L} |\nabla \varphi_{L,n} - \nabla \bar{\varphi}_L|^2 dx \right)^{\frac{1}{2}}.
\]

(3.13)

Then, by the \(L^2(\Omega_L)\) strong convergence of the sequence of \(\{\varphi_{L,n}\}\), we have that

\[
\int_{S_L^+} |\bar{\varphi}_{L,n} - \bar{\varphi}_L| dx' \to 0, \quad \text{as } n \to \infty.
\]

(3.14)

Therefore, it follows from (3.12) and (3.14) that \(J(\bar{\varphi}_L) \leq \liminf_{n \to \infty} J(\varphi_{L,n}) = \alpha\), which means

\[
J(\bar{\varphi}_L) = \min_{\varphi \in H_L} J(\varphi) = \alpha.
\]

(3.15)

**Step 3.** The uniqueness of the minimizer. If there are two minimizers \(\varphi_1 \in H_L\) and \(\varphi_2 \in H_L\), then we know that

\[
J(\varphi_1) = J(\varphi_2) \leq J\left(\frac{\varphi_1 + \varphi_2}{2}\right).
\]
So
\[ 0 \geq J(\varphi_1) + J(\varphi_2) - 2 J\left(\frac{\varphi_1 + \varphi_2}{2}\right) \]
\[ = \frac{1}{2} \int_{\Omega_L} (|\nabla \varphi_1|^2 + |\nabla \varphi_2|^2 - 2|\nabla \left(\frac{\varphi_1 + \varphi_2}{2}\right)|^2) dx \]
\[ \geq \frac{1}{4} \int_{\Omega_L} |\nabla (\varphi_1 - \varphi_2)|^2 dx. \]

By the fact that \( \varphi_1 = \varphi_2 = 0 \) on \( S_L^- \), we know that \( \varphi_1 = \varphi_2 \). Therefore, the minimizer is unique.

**Step 4.** We will show (3.10) in this step. By direct computation and (3.11),
\[ \int_{\Omega_L} |\nabla \bar{\varphi}_L|^2 dx = J(\bar{\varphi}_L) + \frac{m}{|S_L^+|} \int_{S_L^+} \bar{\varphi}_L dx' \leq J(0) + \frac{m}{|S_L^+|} \int_{S_L^+} \bar{\varphi}_L dx' \leq C \frac{m}{|S_L^+|} \|\nabla \bar{\varphi}_L\|_{L^2}. \]

That is
\[ \frac{1}{|\Omega_L|} \int_{\Omega_L} |\nabla \bar{\varphi}_L|^2 dx \leq C \frac{m^2}{|S_L^+|^2} \leq C \frac{m^2}{S_{\text{min}}^2}, \]
where \( S_{\text{min}} \) is defined to be the minimum of \( |S_L^+| \).

For the regularity of the solution of Problem I2 \((m, L)\), by the standard elliptic estimate (cf. see [23]), we have the following lemma:

**Lemma 3.1.** Assume (2.1) holds, then there are constants \( 0 < \alpha < 1 \) and \( C \) depending on \( \Omega_L \) such that for any solution \( \bar{\varphi}_L \in H_L \) of Problem I2 \((m, L)\), we have
\[ \sup_{x \in \Omega_L/2} |\nabla \bar{\varphi}_L| \leq C \left( \|\nabla \bar{\varphi}_L\|^2_{L^2(\Omega_L)} \right), \]
and
\[ \sup_{x_1, x_2 \in \Omega_L/2} \frac{|\nabla \bar{\varphi}_L(x_1) - \nabla \bar{\varphi}_L(x_2)|}{|x_1 - x_2|^\alpha} \leq C \left( \|\nabla \bar{\varphi}_L\|^2_{L^2(\Omega_L)} \right). \]

We omit the proof since it is standard.

### 3.2. Compressible potential flow.

Now let us consider the compressible case. By (2.6), we can introduce the velocity potential \( \varphi^{(\epsilon)} \) for the compressible case such that
\[ \nabla \varphi^{(\epsilon)} = u^{\epsilon}. \]

Then Problem \((m)\) for the compressible case becomes

**Problem C1** \((m)\). Let \( n \geq 2 \). Find function \( \varphi^{(\epsilon)} \) such that
\[ \begin{cases} \text{div} \left( \rho^{\epsilon} |\nabla \varphi^{(\epsilon)}|^2, \varphi \right) \nabla \varphi^{(\epsilon)} = 0, & x \in \Omega, \\ \frac{\partial \varphi^{(\epsilon)}}{\partial n} = 0, & x \in \partial \Omega, \\ \int_{S_0} \rho^{\epsilon} |\nabla \varphi^{(\epsilon)}|^2 n \varphi^{(\epsilon)} ds = m. \end{cases} \]

By the straightforward computation, (3.19) can be rewritten as
\[ \sum_{i,j=1}^n a^{\epsilon}_{ij} \partial_j \varphi^{(\epsilon)} + \sum_{i=1}^n b^i \partial_i \varphi^{(\epsilon)} = 0, \]
(3.20)
where
\[ a_{ij} = \rho^\varepsilon \left( \delta_{ij} - \frac{\varepsilon^2 \partial_i \varphi^{(e)} \partial_j \varphi^{(e)}}{\bar{p}'(\rho^\varepsilon)} \right), \quad (3.21) \]
and
\[ b_i^\varepsilon = \frac{\varepsilon^2 \rho^\varepsilon \partial_i \varphi}{\bar{p}'(\rho^\varepsilon)}. \quad (3.22) \]

For \( 0 < \varepsilon < 1 \) and \( M^\varepsilon < \theta < 1 \), we have that
\[ 0 < \lambda_1 |\xi|^2 \leq \sum_{i,j=1}^{n} a_{ij}^\varepsilon \xi_i \xi_j \leq \lambda_2 |\xi|^2, \quad (3.23) \]
where constants \( \lambda_1 \) and \( \lambda_2 \) do not depend on \( \varepsilon \).

Since equation (3.20) is nonlinear, and is strictly elliptic if and only if \( M^\varepsilon(\phi) < 1 \). We do not know whether equation (3.20) is elliptic or not before solving it. Therefore we need to introduce the subsonic cut-off to truncate the coefficients of equation (3.20). For \( 0 < \varepsilon_0 < 1 \) and \( 0 < \theta < 1 \), we introduce \( \hat{q}_\theta^{(e)}(\phi) = \inf_{0 < \varepsilon < \varepsilon_0} q_\theta(\phi) \), and cut-off function on the phase plane
\[
\hat{q}(q^2, \phi) = \begin{cases} 
q^2 - 2\phi & \text{if } |q| \leq \hat{q}_\theta^{(e)}(\phi), \\
\text{monotone smooth function} & \text{if } \hat{q}_\theta^{(e)}(\phi) \leq |q| \leq \hat{q}_{\theta+1}^{(e)}(\phi), \\
\sup_{x \in \Omega} \left( \left( \frac{\hat{q}_\theta^{(e)}}{2} \right)^2 \phi \right) & \text{if } |q| \geq \hat{q}_{\theta+1}^{(e)}(\phi). 
\end{cases}
\]

Let \( \hat{\rho}^{(e)} \) satisfy
\[ \hat{q}(|u|^2, \phi) + h^{(e)}(\hat{\rho}^{(e)}) - h^{(e)}(1) = 0, \quad (3.24) \]
which is equivalent to
\[ \hat{\rho}^\varepsilon = \hat{\rho}^{(e)}(|u|^2, \phi) = \tilde{h}^{-1} \left( \tilde{h}(1) - \frac{\varepsilon^2 \hat{q}(|u|^2, \phi)}{2} \right). \quad (3.25) \]

We denote \( \hat{\rho}_A^{(e)}(\Lambda, \phi) := \frac{\partial}{\partial \Lambda} \hat{\rho}^\varepsilon(\Lambda, \phi) \), and \( \hat{\rho}_\theta^{(e)}(\Lambda, \phi) := \frac{\partial}{\partial \theta} \hat{\rho}^\varepsilon(\Lambda, \phi) \).

Then, Problem C1 (m) is reformulated into Problem C2 (m) as follows.

Problem C2 (m): Let \( n \geq 2 \). Find function \( \varphi^{(e)} \) to satisfy
\[
\left\{ \begin{array}{l}
\div \left( \hat{\rho}^\varepsilon (|\nabla \varphi^{(e)}|^2, \phi) \nabla \varphi^{(e)} \right) = 0, \quad x \in \Omega, \\
\frac{\partial \varphi^{(e)}}{\partial n} = 0, \quad x \in \partial \Omega, \\
\int_{\Sigma_0} \hat{\rho}^\varepsilon (|\nabla \varphi^{(e)}|^2) \frac{\partial \varphi^{(e)}}{\partial n} ds = m.
\end{array} \right. \quad (3.26)
\]

By the straightforward calculation, we know that (3.26) can be rewritten as
\[
\sum_{i,j=1}^{n} \hat{a}_{ij}(\nabla \varphi^{(e)}(\phi) \partial_{ij} \varphi^{(e)}) + \sum_{i=1}^{n} \hat{b}_i(\nabla \varphi^{(e)}(\phi) \partial_i \varphi^{(e)}) = 0,
\]
where
\[
\hat{a}_{ij}(\nabla \varphi^{(e)}(\phi)) = \hat{\rho}^\varepsilon (|\nabla \varphi^{(e)}|^2, \phi) \left( \delta_{ij} - \frac{\hat{q}_\Lambda(|\nabla \varphi^{(e)}|^2, \phi) \partial_i \varphi^{(e)} \partial_j \varphi^{(e)}}{(\hat{\rho}^\varepsilon)^2} \right)
= \hat{\rho}^\varepsilon (|\nabla \varphi^{(e)}|^2) \left( \delta_{ij} - \frac{\varepsilon^2 \hat{q}_\Lambda(|\nabla \varphi^{(e)}|^2, \phi) \partial_i \varphi^{(e)} \partial_j \varphi^{(e)}}{\bar{p}'(\hat{\rho}^\varepsilon)} \right), \quad (3.27)
\]
and
\[ \hat{b}_i (\nabla \varphi^{(e)}, \phi) = \frac{\varepsilon^2 \hat{p}^2 \hat{q}_\phi (|\nabla \varphi^{(e)}|^2, \phi) \partial_i \phi}{\hat{p} (\hat{p}^2)}. \] (3.28)

Obviously,
\[ \hat{\lambda}_1 \hat{\lambda}_1 \xi^2 \leq \sum_{i,j=1}^{n} \hat{a}_{ij} (\nabla \varphi^{(e)}, \phi) \xi_i \xi_j \leq \hat{\lambda}_2 |\xi|^2, \quad |\hat{b}_i (\nabla \varphi^{(e)}, \phi)| \leq C |\partial_i \phi|, \] (3.29)

where constants \( C, \hat{\lambda}_1, \) and \( \hat{\lambda}_2 \) depend only on the subsonic truncation parameters \( \theta \) and \( \varepsilon_0 \), and do not depend on solution \( \varphi^{(e)} \).

Next, as in the previous subsection for the incompressible case, we approximate Problem \( \hat{C}_1 (m) \) for any \( L \) sufficiently large, by considering the following approximate problem:

**Problem C3** \((m, L)\): For any sufficiently large \( L > 0 \), find a function \( \varphi_L^{(e)} \) such that,

\[
\begin{aligned}
\text{div} (\hat{\rho} (|\nabla \varphi_L^{(e)}|^2, \phi) \nabla \varphi_L^{(e)}) &= 0, \quad x \in \Omega_L, \\
\frac{\partial \varphi_L^{(e)}}{\partial n} &= 0, \quad \partial \Omega \cap \partial \Omega_L, \\
\hat{\rho} (|\nabla \varphi_L^{(e)}|^2, \phi) \frac{\partial \varphi_L^{(e)}}{\partial x_n} &= \frac{m}{|S_L^+|}, \quad \text{on } S_L^+, \\
\varphi_L^{(e)} &= 0, \quad \text{on } S_L^-.
\end{aligned}
\] (3.30)

Similarly to the incompressible case, we will solve Problem C3 \((m, L)\) by a variational approach. Here, we follow the idea used in [14] to introduce a variational formulation. Denote
\[ G^{(e)} (\Lambda, \phi) = \frac{1}{2} \int_0^\Lambda \hat{\rho}^{(e)} (\lambda, \phi) d\lambda. \]

In order to compare the solutions of Problem I2 \((m, L)\) and Problem C3 \((m, L)\), we introduce
\[ I^{(e)} (\varphi, \varphi_L) = \varepsilon^{-4} \int_\Omega \left[ G^{(e)} (|\nabla \varphi|^2, \phi) - G^{(e)} (|\nabla \varphi_L|^2, \phi) - \nabla \varphi_L \cdot (\nabla \varphi - \nabla \varphi_L) \right] dx. \] (3.31)

Define
\[ \tilde{\varphi} = \frac{\varphi - \varphi_L}{\varepsilon^2} \quad \text{and} \quad \tilde{\varphi}_L^{(e)} = \frac{\varphi_L^{(e)} - \varphi_L}{\varepsilon^2}. \] (3.32)

Obviously, both \( \varphi_L^{(e)} \) and \( \tilde{\varphi}_L^{(e)} \) belong to \( H_L \). Then in order to apply the variational approach to find solutions of Problem C3 \((m, L)\), let us consider the following problem that

**Problem C4** \((m, L)\): Find a minimizer \( \tilde{\varphi}_L^{(e)} \in H_L \) such that
\[ I^{(e)} (\tilde{\varphi}_L + \varepsilon^2 \tilde{\varphi}_L^{(e)}, \tilde{\varphi}_L) = \min_{\varphi \in H_L} I^{(e)} (\varphi_L + \varepsilon^2 \varphi, \varphi_L). \] (3.33)

For Problem C4 \((m, L)\), we have the following theorem:
Theorem 3.2. Problem C4 \((m, L)\) admits a unique minimizer \(\varphi^{(e)}_L \in H_L\). Moreover, the minimizer \(\varphi^{(e)}_L\) satisfies that

\[
\frac{1}{|\Omega_L|} \int_{\Omega_L} |\nabla \varphi^{(e)}_L|^2 dx \leq Cm^2, \tag{3.34}
\]

where constant \(C\) does not depend on \(L\).

Proof. The proof is divided into four steps.

Step 1. \(I^{(e)}(\varphi_L + \varepsilon \bar{\varphi}, \bar{\varphi}_L) = I^{(e)}(\varphi, \bar{\varphi}_L)\) is coercive with respect to \(\varphi\) on \(H_L\), i.e., we will show that

\[
I^{(e)}(\varphi, \bar{\varphi}_L) \geq \frac{C_1}{2} \int_{\Omega_L} |\nabla \bar{\varphi}|^2 dx - C_2 \int_{\Omega_L} |\nabla \bar{\varphi}_L|^2 dx. \tag{3.35}
\]

Let

\[
I^{(e)}(\varphi, \bar{\varphi}_L) = I^{(e)}_1(\varphi, \bar{\varphi}_L) + I^{(e)}_2(\varphi, \bar{\varphi}_L), \tag{3.36}
\]

where

\[
I^{(e)}_1(\varphi, \bar{\varphi}_L) = \varepsilon^{-4} \int_{\Omega_L} \left[ G^{(e)} \left( |\nabla \varphi|^2, \phi \right) - G^{(e)} \left( |\nabla \bar{\varphi}_L|^2, \phi \right) - 2G^{(e)}_\Lambda \left( |\nabla \bar{\varphi}_L|^2, \phi \right) \nabla \bar{\varphi}_L \cdot (\nabla \varphi - \nabla \bar{\varphi}_L) \right] dx,
\]

and

\[
I^{(e)}_2(\varphi, \bar{\varphi}_L) = \varepsilon^{-4} \int_{\Omega_L} \left( 2G^{(e)}_\Lambda \left( |\nabla \bar{\varphi}_L|^2, \phi \right) - 1 \right) \nabla \bar{\varphi}_L \cdot (\nabla \varphi - \nabla \bar{\varphi}_L) dx.
\]

First, we will show that \(I^{(e)}_1(\varphi, \bar{\varphi}_L)\) is coercive with respect to \(\varphi\) in \(H_L\).

Let \(p = (p_1, \cdots, p_n)\), and let \(F^{(e)}(p) = G^{(e)}(|p|^2, \phi)\). By straightforward computation, we can get that

\[
G^{(e)} \left( |\nabla \varphi|^2, \phi \right) - G^{(e)} \left( |\nabla \bar{\varphi}_L|^2, \phi \right) - 2G^{(e)}_\Lambda \left( |\nabla \bar{\varphi}_L|^2, \phi \right) \nabla \bar{\varphi}_L \cdot (\nabla \varphi - \nabla \bar{\varphi}_L)
\]

\[
= F^{(e)}(\nabla \varphi) - F^{(e)}(\nabla \bar{\varphi}) - \nabla F^{(e)}(\nabla \bar{\varphi}) \cdot (\nabla \varphi - \nabla \bar{\varphi})
\]

\[
= \sum_{i,j=1}^{n} \int_0^1 (1-t) \partial_{p_ip_j} F^{(e)}(t \nabla \varphi + (1-t) \nabla \bar{\varphi}) dt \partial_i(\varphi - \bar{\varphi}) \partial_j(\varphi - \bar{\varphi}).
\]

It is easy to check that \(\partial_{pp}^2 F^{(e)}\) is uniformly positive due to the subsonic cut-off. In fact, we have

\[
(\partial_{pp}^2 F^{(e)}(p))_{i,j} = \hat{a}_{ij}. \tag{3.37}
\]

From property (3.29), we get the uniformly positivity of \(\partial_{pp}^2 F\). As a consequence, we have

\[
C_1 \int_{\Omega_L} |\nabla \bar{\varphi}|^2 dx \leq I^{(e)}_1(\varphi, \bar{\varphi}_L) \leq \tilde{C}_1 \int_{\Omega_L} |\nabla \bar{\varphi}_L|^2 dx. \tag{3.38}
\]
Now, let us consider $I_2^{(e)}(\varphi, \varphi_L)$. Note that
\[
\left| \varepsilon^{-2} \left( 2G_A^{(e)} \left( |\nabla \varphi_L|^2, \phi \right) - 1 \right) \right| = \left| \varepsilon^{-2} \left( \hat{\rho}^{(e)} \left( |\nabla \varphi_L|^2, \phi \right) - 1 \right) \right|
\leq \varepsilon^{-2} \left( -\varepsilon^2 \hat{q} \left( |\nabla \varphi_L|^2, \phi \right) + \hat{h}(1) \right)
\leq \varepsilon^{-2} \left( -\varepsilon^2 \hat{q} \left( |\nabla \varphi_L|^2, \phi \right) + \hat{h}(1) \right) - \varepsilon^{-4} \left( -\varepsilon^2 \hat{q} \left( |\nabla \varphi_L|^2, \phi \right) + \hat{h}(1) \right) dt
\leq C,
\]
where constant $C$ is independent of $\varepsilon$. Then
\[
\left| I_2^{(e)}(\varphi, \varphi_L) \right| = \left| \varepsilon^{-4} \int_{\Omega_L} \left[ \left( 2G_A^{(e)} \left( |\nabla \varphi_L|^2, \phi \right) - 1 \right) \nabla \varphi_L \cdot (\nabla \varphi - \nabla \varphi_L) \right] dx \right|
\leq C \varepsilon^{-2} \int_{\Omega_L} \nabla \varphi_L \nabla (\varphi - \varphi_L) dx
\leq C \int_{\Omega_L} |\nabla \varphi_L|^2 dx + \frac{C_1}{2} \varepsilon^{-4} \int_{\Omega} |\nabla (\varphi - \varphi_L)|^2 dx
= C \int_{\Omega_L} |\nabla \varphi_L|^2 dx + \frac{C_1}{2} \int_{\Omega_L} |\nabla \varphi|^2 dx.
\]
By (3.38) and (3.40), we get (3.35). It also implies that $I^{(e)}(\varphi, \varphi_L)$ is bounded from below, i.e., there exists a constant $C > 0$ such that, for all $\check{\varphi} \in H_L$,
\[
I^{(e)}(\varphi, \varphi_L) \geq -C.
\]

**Step 2.** Note that $\Omega_L$ is a bounded domain, so $I^{(e)}(\varphi, \varphi_L) = I^{(e)}(\varphi_L + \varepsilon^2 \tilde{\varphi}, \varphi_L)$ is finite for any $\check{\varphi} \in H_L$. Moreover, by (3.38) and (3.40), we can also show that
\[
I^{(e)}(\varphi, \varphi_L) \leq C_1 + 2\hat{C}_1 \int_{\Omega_L} |\nabla \check{\varphi}|^2 dx + C_3 \int_{\Omega_L} |\nabla \varphi_L|^2 dx.
\]

**Step 3.** We will prove that $I^{(e)}(\varphi, \varphi_L)$ is uniformly convex in space $H_L$.

Note that $I_2^{(e)}(\varphi, \varphi_L)$ is linear with respect to $\varphi$. Then for any $\varphi_1, \varphi_2 \in H_L$, we have that
\[
I^{(e)}(\varphi_1, \varphi_L) + I^{(e)}(\varphi_2, \varphi_L) - 2I^{(e)} \left( \frac{\varphi_1 + \varphi_2}{2}, \varphi_L \right)
= \left( \varphi_1 + \varphi_2 \right) \left( \frac{\nabla \varphi_1 + \nabla \varphi_2}{2} \right) dx
\geq \varepsilon^{-4} \left| \nabla \varphi_1 - \nabla \varphi_2 \right|^2_{L^2}
= \frac{C_1}{2} \left| \nabla \varphi_1 - \nabla \varphi_2 \right|^2_{L^2}.
\]
It is the uniform convexity of $I^e$.

**Step 4.** We are now ready to show the unique existence of the minimizer $\hat{\varphi}^e \in H_L$ of Problem C4 ($m$, $L$), which satisfies (3.34).

Firstly, we will show the continuity of $I^e(\hat{\varphi}_L + \varepsilon \hat{\varphi}, \hat{\varphi}_L)$ with respect to $\hat{\varphi}$ in $H_L$. Let $\hat{\varphi}_1$ and $\hat{\varphi}_2$ in $H_L$, correspond to $\varphi_1$ and $\varphi_2$ via (3.32) respectively. We have

$$I^e(\varphi_1, \hat{\varphi}_L) - I^e(\varphi_2, \hat{\varphi}_L) = \varepsilon^4 \int_{\Omega_L} \left[ \frac{1}{2} \int_{|\nabla \varphi_1|^2} \hat{\rho}^e(\Lambda, \phi) d\Lambda - \nabla \hat{\varphi}_L \cdot \nabla (\varphi_1 - \varphi_2) \right] dx$$

$$= \varepsilon^4 \int_{\Omega_L} \left[ \frac{1}{2} \int_{|\nabla \varphi_2|^2} \hat{\rho}^e(\Lambda, \phi) d\Lambda - \hat{\rho}^e(|\nabla \hat{\varphi}_L|^2) \nabla \hat{\varphi}_L \cdot \nabla (\varphi_1 - \varphi_2) \right] dx$$

$$+ \varepsilon^{-2} \int_{\Omega_L} \left[ \varepsilon^2 \hat{\rho}^e(|\nabla \hat{\varphi}_L|^2, \phi) - 1 \right] \nabla \hat{\varphi}_L \cdot \nabla (\varphi_1 - \varphi_2) dx$$

Similar to the argument as done in Step 1 to obtain (3.38) and (3.40), and by the H"older inequality, we have:

$$\left| I^e(\varphi_1, \hat{\varphi}_L) - I^e(\varphi_2, \hat{\varphi}_L) \right|$$

$$\leq \frac{\bar{C}_1}{2} \int_{\Omega_L} |\nabla (\hat{\varphi}_1 - \hat{\varphi}_2)|^2 dx + C\varepsilon^{-2} \int_{\Omega_L} |\nabla \hat{\varphi}_L| |\nabla (\varphi_1 - \varphi_2)| dx$$

$$\leq C ||\nabla \hat{\varphi}_1 - \nabla \hat{\varphi}_2||_{L^2}^2 + C ||\nabla \varphi_1 - \nabla \varphi_2||_{L^2}.$$  

(3.44)

Then we have proved the continuity of the functional $I^e(\hat{\varphi}_L + \varepsilon \hat{\varphi}, \hat{\varphi}_L)$ with respect to $\hat{\varphi}$ in $H_L$. Based on it, we can show the existence of the minimizer $\hat{\varphi}^e$ by the standard compactness argument via selecting a subsequence from the subsequence of $\hat{\varphi}^e$, where $I^e(\hat{\varphi}_L + \varepsilon \hat{\varphi}^e, \hat{\varphi}_L)$ converges to the minimal value of the functional $I^e(\hat{\varphi}_L + \varepsilon \hat{\varphi}, \hat{\varphi}_L)$ in $H_L$.

For the uniqueness, if $\varphi_1$ and $\varphi_2$ are two minimizers such that

$$I^e(\varphi_1, \hat{\varphi}_L) = I^e(\varphi_2, \hat{\varphi}_L) \leq I^e(\frac{\varphi_1 + \varphi_2}{2}, \hat{\varphi}_L).$$

Then by (3.43), we know that

$$0 \geq I^e(\varphi_1, \hat{\varphi}_L) + I^e(\varphi_2, \hat{\varphi}_L) - 2I^e(\frac{\varphi_1 + \varphi_2}{2}, \hat{\varphi}_L) \geq \frac{\bar{C}_1}{2} \varepsilon^{-4} ||\nabla \varphi_1 - \nabla \varphi_2||_{L^2}^2.$$  

(3.45)

Therefore,

$$\nabla \varphi_1 - \nabla \varphi_2 = 0.$$  

(3.46)

Note that $\varphi_1, \varphi_2 \in H_L$. So $\varphi_1 = \varphi_2$. It means that the minimizer is unique in $H_L$.

Finally, replacing $\varphi$ by $\varphi_L$, we know that $I^e(\varphi, \hat{\varphi}_L) \leq I^e(\hat{\varphi}_L, \hat{\varphi}_L)$. So (3.35) leads to

$$\int_{\Omega_L} |\nabla \varphi|^2 dx \leq C \int_{\Omega_L} |\nabla \hat{\varphi}_L|^2 dx,$$  

(3.47)

which leads to (3.34) from (3.10).

Next, we will show that the minimizer of Problem C4 ($m$, $L$) is actually a solution of Problem C3 ($m$, $L$).

**Proposition 3.3.** The minimizer of Problem C4 ($m$, $L$) satisfies equations (3.30).
Proof. For any \( t \in \mathbb{R}_+ \) and for any \( \eta \in H_L \), we have that \( \varphi^{(e)}_L + t\eta \in H_L \). Then,

\[
0 \leq \lim_{t \to 0^+} \frac{1}{t} \left( I^{(e)}(\varphi^{(e)}_L + t\eta, \bar{\varphi}_L) - I^{(e)}(\varphi, \bar{\varphi}_L) \right)
\]

\[
= \lim_{t \to 0^+} \frac{1}{t} \epsilon^{-4} \int_{\Omega_L} \left[ G^{(e)}(\|
abla(\varphi^{(e)}_L + t\eta)\|^2, \phi) - G^{(e)}(\|
abla \bar{\varphi}_L\|^2, \phi) - \nabla \bar{\varphi}_L \cdot \left( \nabla(\varphi^{(e)}_L + t\eta) - \nabla \bar{\varphi}_L \right) \right] dx
\]

\[
= \epsilon^{-4} \int_{\Omega} \left[ 2G^{(e)}_\Lambda (\|
abla \bar{\varphi}_L\|^2, \phi) \nabla \bar{\varphi}_L \cdot \nabla \eta - \nabla \bar{\varphi}_L \cdot \nabla \eta \right] dx
\]  

(3.48)

Note that \( \eta \) is arbitrary, so

\[
\int_{\Omega_L} \rho^{(e)}(\|
abla \bar{\varphi}_L\|^2, \phi) \nabla \bar{\varphi}_L \cdot \nabla \eta dx = \int_{\Omega} \left[ 2G^{(e)}_\Lambda (\|
abla \bar{\varphi}_L\|^2, \phi) \nabla \bar{\varphi}_L \cdot \nabla \eta \right] dx
\]

\[
= \int_{\Omega_L} \nabla \bar{\varphi}_L \cdot \nabla \eta dx
\]

\[
= \frac{m}{|S_L^+|} \int_{S_L^+} \eta dx'.
\]

Then (3.30) follows by the integration by part. \( \square \)

Finally, for the regularity of solution of Problem \( C_3 \) \((m, L)\), by the standard elliptic estimate (cf. see [23]), we actually have the following lemma.

**Lemma 3.2.** Assume (2.1) holds, then there exist constants \( 0 < \alpha < 1 \) and \( C \) depending on \( \Omega_L \) such that for any solution \( \varphi_L \) of Problem \( C_3 \) \((m, L)\), we have the same estimates as the ones in Lemma 3.1 by replacing \( \bar{\varphi}_L \) by \( \varphi_L \).

4. Existence of Solutions of Problem \( I_1 \) \((m)\) and Problem \( C_2 \) \((m)\)

In order to pass the limit \( L \to \infty \) to obtain solutions of Problem \( I_1 \) \((m)\) and Problem \( C_2 \) \((m)\) from solutions of Problem \( I_1 \) \((m, L)\) or Problem \( C_1 \) \((m, L)\) respectively, we need to derive the uniform estimate of solutions of Problem \( I_1 \) \((m, L)\) or Problem \( C_2 \) \((m, L)\) with respect \( L \). It is the local average estimate.

For the local average estimate, we need to introduce the local set: For \( x_0 = (x_0', x_{0n}) \in \Omega \), let

\[
\Omega_{(a,b)} := \{ x = (x', x_n) \in \Omega \mid a < x_n < b \},
\]

and define

\[
P_{(a,b)}(\varphi) = \frac{1}{|\Omega_{(a,b)}|} \int_{\Omega_{(a,b)}} \varphi(x) dx.
\]  

(4.1)

First, from the properties of the nozzle (2.1), we have the following lemma and proposition of the Poincaré inequality.

**Lemma 4.1** (Uniform Poincaré Inequality). For any \( a \in \mathbb{R}, 1 \leq p < \infty \), one has

\[
\| \varphi(x) - P_{(a,a+1)}(\varphi) \|_{L^p(\Omega_{(a,a+1)})} \leq C \| \nabla \varphi(x) \|_{L^p(\Omega_{(a,a+1)})},
\]

(4.2)

where \( C \) is a positive constant depending only on \( p, \Omega \), independent of \( a \).
This lemma is Theorem 3 in [15], so we omit the proof.

Moreover, in $\Omega$, it follows from Lemma 4.1 that we also have the following Poincaré type inequality.

**Proposition 4.1.** For $a < b$, one can obtain:

\[
|P_{[a-1,a]}(\varphi) - P_{[b,b+1]}(\varphi)| \leq C \int_{\Omega_{(a-1,b+1)}} |\nabla \varphi| dx,
\]

where constant $C$ only depends on $\Omega$ and does not depend on $a$ and $b$.

Based on the inequalities, we will introduce the local average lemma case by case.

### 4.1. The local average lemma for the incompressible case

Now, let us introduce the local average lemma for the incompressible case firstly.

**Lemma 4.2.** There is a uniform $L$ depending only on $\Omega$, such that for any $b - a > L$ and $\Omega_{(a-1,b+1)} \subset \Omega_{\frac{a+b}{2}}$, the solution $\tilde{\varphi}_L$ of equations (3.5) satisfies

\[
\frac{1}{|\Omega_{(a,b)}|} \int_{\Omega_{(a,b)}} |\nabla \tilde{\varphi}_L|^2 dx \leq Cm^2,
\]

where $C$ does not depend on $L$.

**Proof.** For any $\frac{b-a}{2} < a - 1 < a < b < b + 1 < \frac{b + a}{2}$, let $\eta$ be a smooth function such that $\eta \in C^{\infty}(\Omega_L)$, $0 \leq \eta \leq 1$, $|\nabla \eta| \leq 1$, $\eta|_{\Omega_{(a,b)}} = 1$, and $\eta|_{\Omega - \Omega_{(a-1,b+1)}} = 0$.

Then, define the test function as $\eta^2 \tilde{\phi} \in H^1(\Omega_L)$, where

\[
\tilde{\phi}(x) = \begin{cases} 
\tilde{\varphi}_L(x) - P_{[a-1,a]}(\tilde{\varphi}_L), & x_n \leq a, \\
\tilde{\varphi}_L(x) - P_{[a-1,a]}(\tilde{\varphi}_L) - (P_{[b,b+1]}(\tilde{\varphi}_L) - P_{[a-1,a]}(\tilde{\varphi}_L)) \frac{x_n - a}{b - a}, & a \leq x_n \leq b, \\
\tilde{\varphi}_L(x) - P_{[b,b+1]}(\tilde{\varphi}_L), & x_n \geq b.
\end{cases}
\]

Obviously, $\eta^2 \tilde{\phi} \in H_L$. From equations (3.5) and by the integration by part, we have

\[
\int_{\Omega_L} \nabla \tilde{\varphi}_L \cdot \nabla (\eta^2 \tilde{\phi}) dx = 0.
\]

Note that $\nabla \tilde{\phi} = \nabla \tilde{\varphi}_L - \frac{P_{[b,b+1]}(\tilde{\varphi}_L) - P_{[a-1,a]}(\tilde{\varphi}_L)}{b - a} \chi_{(a,b)}(x) \tilde{e}_n$, where $\tilde{e}_n = (0, \cdots, 0, 1)$, and $\chi_{(a,b)}(x)$ is the characteristic function of $\Omega_{(a,b)}$.

Therefore,

\[
\int_{\Omega_{(a-1,b+1)}} \eta^2 |\nabla \tilde{\varphi}_L|^2 dx - \int_{\Omega_{(a,b)}} \eta^2 \frac{\partial \tilde{\varphi}_L}{\partial x_n} \left( \frac{P_{[b,b+1]}(\tilde{\varphi}_L) - P_{[a-1,a]}(\tilde{\varphi}_L)}{b - a} \right) dx
\]

\[= -2 \int_{\Omega_{(a-1,b+1)}} \eta \nabla \tilde{\varphi}_L \cdot \nabla \eta \tilde{\phi} dx.
\]

Note that for any $a < x_n < b$, the conservation of mass flux (1.5) implies that

\[
\int_{S_{x_n}} \frac{\partial \tilde{\varphi}_L}{\partial x_n} dx' = m.
\]
Then, we have
\[
\int_{\Omega(a,b+1)} \eta^2 |\nabla \varphi_L|^2 \, dx = -2 \int_{\Omega(a,b+1)} \eta \nabla \varphi_L \cdot \nabla \eta \hat{\phi} \, dx + (P_{b,b+1}(\varphi_L) - P_{a-1,a}(\varphi_L)) m.
\]

Consequently, by the fact that \( \nabla \eta = 0 \) on \( \Omega(a,b) \), we have
\[
\int_{\Omega(a,b)} |\nabla \varphi_L|^2 \, dx \leq \int_{\Omega(a-1,b+1)} \eta^2 |\nabla \varphi_L|^2 \, dx
\]
\[
\leq 2 \int_{\Omega(a-1,a) \cup \Omega(b,b+1)} \eta \nabla \varphi_L \cdot \nabla \eta \hat{\phi} \, dx + |P_{b,b+1}(\varphi_L) - P_{a-1,a}(\varphi_L)| \, m
\]
\[
\leq C \left( \int_{\Omega(a-1,a) \cup \Omega(b,b+1)} |\nabla \varphi_L| \hat{\phi} \, dx \right)^{\frac{1}{2}} \left( \int_{\Omega(a-1,a)} |\varphi_L - P_{a-1,a}(\varphi_L)|^2 \, dx \right)^{\frac{1}{2}}
\]
\[
+C \left( \int_{\Omega(b,b+1)} |\nabla \varphi_L|^2 \, dx \right)^{\frac{1}{2}} \left( \int_{\Omega(b,b+1)} |\varphi_L - P_{b,b+1}(\varphi_L)|^2 \, dx \right)^{\frac{1}{2}} + |P_{b,b+1}(\varphi_L) - P_{a-1,a}(\varphi_L)| \, m.
\]

Then, by Lemma 4.1, Proposition 4.1 and (4.6), we know that
\[
\int_{\Omega(a,b)} |\nabla \varphi_L|^2 \, dx \leq C_1 \int_{\Omega(a-1,b+1) - \Omega(a,b)} |\nabla \varphi_L|^2 \, dx + C_2 m \int_{\Omega(a-1,b+1)} |\nabla \varphi_L| \, dx
\]  
(4.7)

where \( C_1 \) and \( C_2 \) are two uniform positive constants.

On the other hand, for any \( \delta \ll 1 \), we have
\[
m \int_{\Omega(a-1,b+1)} |\nabla \varphi_L| \, dx \leq \delta \int_{\Omega(a-1,b+1)} |\nabla \varphi_L|^2 \, dx + \frac{1}{4\delta} |\Omega(a-1,b+1)| m^2.
\]  
(4.8)

Here \( |\Omega(a-1,b+1)| \) is the measure of \( \Omega(a-1,b+1) \). Combining (4.7) and (4.8) together, we have
\[
\int_{\Omega(a,b)} |\nabla \varphi_L|^2 \, dx \leq \left( \frac{C_1 + C_2 \delta}{C_1 + 1} \right) \int_{\Omega(a-1,b+1)} |\nabla \varphi_L|^2 \, dx + \frac{C_2}{4\delta(C_1 + 1)} |\Omega(a-1,b+1)| m^2.
\]

Introduce
\[A_{(a,b)} = \frac{1}{b-a} \int_{\Omega(a,b)} |\nabla \varphi_L|^2 \, dx.\]

Then it becomes
\[A_{(a,b)} \leq \left( \frac{C_1 + C_2 \delta}{C_1 + 1} \right) \frac{b-a + 2}{b-a} A_{(a-1,b+1)} + \frac{C_2}{4\delta(C_1 + 1)} |\Omega(a-1,b+1)| \frac{m}{b-a} m^2.\]  
(4.9)

By choosing constant \( \delta \) sufficiently small, one can find the uniform constant \( l \) such that, when \( b-a > l \),
\[
\left( \frac{C_1 + C_2 \delta}{C_1 + 1} \right) \frac{b-a + 2}{b-a} < \vartheta < 1.
\]
Hence, (4.9) becomes
\[ A_{(a,b)} \leq \vartheta A_{(a^{-1},b+1)} + C m^2. \]

By Lemma 8.23 in [23] and (3.10), we know that there exists \( \alpha > 0 \) such that
\[ A_{(a,b)} \leq C \left( \frac{b-a}{2L} \right)^\alpha A_{(-L,L)} + m^2 \leq C \left( \frac{b-a}{2L} \right)^\alpha + 1 \] \( m^2. \)

If \( L > l \), where \( l \) is sufficiently large, then (4.4) holds where the constant \( C \) does not depend on \( L \).

Combining Lemma 3.1, above lemma leads to

**Lemma 4.3.** Assume (2.1) holds, then there are constants \( 0 < \alpha < 1 \) and \( C \) independent of \( L \), for any \( b - a > l \) and \( \Omega_{(a-1,b+1)} \subset \Omega_{\frac{L}{2}} \), such that for any solution \( \bar{\varphi}_L \in H_L \) of Problem I2 \((m, L)\),
\[ \sup_{x \in \Omega_{(a,b)}} |\nabla \varphi_L| \leq C m^2, \]
and
\[ \sup_{x,y \in \Omega_{(a,b)}} \frac{|\nabla \varphi_L(x) - \nabla \varphi_L(y)|}{|x-y|^{\alpha}} \leq C m^2. \]

4.2. The local average lemma for the compressible case. Next, let us consider the average lemma for the compressible case.

**Lemma 4.4.** There is a uniform constant \( l \) depending only on \( \Omega \), such that for any \( b - a > l \) and \( \Omega_{(a-1,b+1)} \subset \Omega_{\frac{L}{2}} \), the solution \( \varphi_L^{(e)} \) of equations (3.30) satisfies
\[ \frac{1}{|\Omega_{(a,b)}|} \int_{\Omega_{(a,b)}} |\nabla \varphi_L^{(e)}|^2 dx \leq C m^2, \]
where constant \( C \) does not depend on \( L \).

**Proof.** For any \(-\frac{L}{2} < a - 1 < a < b < b + 1 < \frac{L}{2}\), define smooth function \( \eta \) such that \( \eta \in C^\infty(\Omega_L) \), \( 0 \leq \eta \leq 1 \), \( |\nabla \eta| \leq 1 \), \( \eta|_{\Omega_{(a,b)}} = 1 \) and \( \eta|_{\Omega - \Omega_{(a-1,b+1)}} = 0 \). Then as done in the proof of Lemma 4.2, we introduce
\[ \hat{\phi}(x) = \begin{cases} \varphi_L^{(e)}(x) - P_{[a-1,a]}(\varphi_L^{(e)}), & x_n \leq a, \\ \varphi_L^{(e)}(x) - P_{[a-1,a]}(\varphi_L^{(e)}) - (P_{[b-1,b]}(\varphi_L^{(e)}) - P_{[a-1,a]}(\varphi_L^{(e)})) \frac{x_n-a}{b-a}, & a \leq x_n \leq b, \\ \varphi_L^{(e)}(x) - P_{[b,b+1]}(\varphi_L^{(e)}), & x_n \geq b. \end{cases} \]

Then the test function \( \eta^2 \hat{\phi} \) satisfies that \( \eta^2 \hat{\phi} \in H^1(\Omega_L) \) and \( (\eta^2 \hat{\phi}) \big|_{x_n=\pm L} = 0 \).

Therefore \( \eta^2 \hat{\phi} \in H_L \) and
\[ \int_{\Omega_L} \left( \rho^e (|\nabla \varphi_L^{(e)}|^2, \phi) \nabla \varphi_L^{(e)} - \nabla \varphi_L^{(e)} \right) \cdot \nabla (\eta^2 \hat{\phi}) dx = 0. \]

So
\[ \int_{\Omega_{(a-1,b+1)}} \eta^2 \left( \rho^e (|\nabla \varphi_L^{(e)}|^2, \phi) \nabla \varphi_L^{(e)} - \nabla \varphi_L^{(e)} \right) \cdot \nabla \hat{\phi} dx \]
\[ = -2 \int_{\Omega_{(a-1,b+1)}} \eta \left( \rho^e (|\nabla \varphi_L^{(e)}|^2, \phi) \nabla \varphi_L^{(e)} - \nabla \varphi_L^{(e)} \right) \cdot \nabla \eta \hat{\phi} dx. \]
Note that $\nabla \hat{\phi} = \nabla \varphi^{(e)}_{L} - \frac{P_{[b,b+1]}(\varphi^{(e)}_{L}) - P_{[a-1,a]}(\varphi^{(e)}_{L})}{b-a} \chi_{a,b}(x) \hat{e}_{n}$. So,

\[
\int_{\Omega_{(a-1,b+1)}} \eta^{2} \left( \rho^{\varepsilon} (|\nabla \varphi^{(e)}_{L}|^{2}, \phi) \nabla \varphi^{(e)}_{L} - \nabla \varphi_{L} \right) \cdot \nabla \varphi^{(e)}_{L} dx \\
+ \int_{\Omega_{(a,b)}} \eta^{2} \left( \rho^{\varepsilon} (|\nabla \varphi^{(e)}_{L}|^{2}, \phi) \frac{\partial \varphi^{(e)}_{L}}{\partial x_{n}} + \frac{\partial \varphi_{L}}{\partial x_{n}} \right) \frac{P_{[b,b+1]}(\varphi^{(e)}_{L}) - P_{[a-1,a]}(\varphi^{(e)}_{L})}{a-b} dx \\
= -2 \int_{\Omega_{(a-1,b+1)}} \eta \left( \rho^{\varepsilon} (|\nabla \varphi^{(e)}_{L}|^{2}, \phi) \nabla \varphi^{(e)}_{L} - \nabla \varphi_{L} \right) \cdot \nabla \eta \hat{\phi} dx. \tag{4.11}
\]

Since $\eta = 1$ on $\Omega_{a,b}$ and $\int_{\Omega_{a,b}} \rho^{\varepsilon} (|\nabla \varphi^{(e)}_{L}|^{2}, \phi) \frac{\partial \varphi^{(e)}_{L}}{\partial x_{n}} dx' = m = \int_{\Omega_{a,b}} \frac{\partial \varphi_{L}}{\partial x_{n}} dx'$, the above identity becomes

\[
\int_{\Omega_{(a-1,b+1)}} \frac{\eta^{2}}{\varepsilon^{2}} \left( \rho^{\varepsilon} (|\nabla \varphi^{(e)}_{L}|^{2}, \phi) \nabla \varphi^{(e)}_{L} - \nabla \varphi_{L} \right) \cdot \nabla \varphi^{(e)}_{L} dx \\
= -\frac{2}{\varepsilon^{2}} \int_{\Omega_{(a-1,b+1)}} \eta \left( \rho^{\varepsilon} (|\nabla \varphi^{(e)}_{L}|^{2}, \phi) \nabla \varphi^{(e)}_{L} - \nabla \varphi_{L} \right) \cdot \nabla \eta \hat{\phi} dx. \tag{4.12}
\]

For the left hand side of the identity above,

\[
\int_{\Omega_{(a-1,b+1)}} \frac{\eta^{2}}{\varepsilon^{2}} \left( \rho^{\varepsilon} (|\nabla \varphi^{(e)}_{L}|^{2}, \phi) \nabla \varphi^{(e)}_{L} - \nabla \varphi_{L} \right) \cdot \nabla \varphi^{(e)}_{L} dx = \int_{\Omega_{(a-1,b+1)}} \eta^{2} \rho^{\varepsilon} (|\nabla \varphi^{(e)}_{L}|^{2}, \phi) |\nabla \varphi^{(e)}_{L}|^{2} dx \\
+ \int_{\Omega_{(a-1,b+1)}} \frac{\eta^{2}}{\varepsilon^{2}} \rho^{\varepsilon} (|\nabla \varphi^{(e)}_{L}|^{2}, \phi) - 1 \nabla \varphi_{L} \cdot \nabla \varphi^{(e)}_{L} dx.
\]

Because $\frac{\rho^{\varepsilon}(|\nabla \varphi^{(e)}_{L}|^{2}, \phi)}{\varepsilon^{2}}$ is bounded, for arbitrary $\nu > 0$,

\[
\left| \int_{\Omega_{(a-1,b+1)}} \frac{\eta^{2}}{\varepsilon^{2}} \rho^{\varepsilon} (|\nabla \varphi^{(e)}_{L}|^{2}, \phi) - 1 \nabla \varphi_{L} \cdot \nabla \varphi^{(e)}_{L} dx \right| \leq \nu \int_{\Omega_{(a-1,b+1)}} |\nabla \varphi^{(e)}_{L}|^{2} dx + C \nu \int_{\Omega_{(a-1,b+1)}} |\nabla \varphi_{L}|^{2} dx.
\]

For the right hand side of the identity (4.12), note that $\nabla \eta = 0$ on $\Omega_{[a-1,b+1]} \setminus \Omega_{[a,b]}$, so

\[
\left| \frac{\varepsilon^{2}}{\eta^{2}} \int_{\Omega_{(a-1,b+1)}} \eta \left( \rho^{\varepsilon} (|\nabla \varphi^{(e)}_{L}|^{2}, \phi) \nabla \varphi^{(e)}_{L} - \nabla \varphi_{L} \right) \cdot \nabla \eta \hat{\phi} dx \right| \\
= \left| \int_{\Omega_{(a-1,b+1)}} \eta \rho^{\varepsilon} (|\nabla \varphi^{(e)}_{L}|^{2}, \phi) \nabla \varphi^{(e)}_{L} \cdot \nabla \eta \hat{\phi} dx + \int_{\Omega_{(a-1,b+1)}} \frac{\eta^{2}}{\varepsilon^{2}} \rho^{\varepsilon} (|\nabla \varphi^{(e)}_{L}|^{2}, \phi) - 1 \nabla \varphi_{L} \cdot \nabla \eta \hat{\phi} dx \right| \\
\leq C_{1} \int_{\Omega_{[a-1,b+1]} \setminus \Omega_{[a,b]}} |\nabla \varphi^{(e)}_{L}| |\hat{\phi}| dx + C_{2} \int_{\Omega_{[a-1,b+1]} \setminus \Omega_{[a,b]}} |\nabla \varphi_{L}| |\hat{\phi}| dx \\
\leq C_{1} \int_{\Omega_{[a-1,b+1]} \setminus \Omega_{[a,b]}} |\nabla \varphi^{(e)}_{L}|^{2} dx + C_{2} \int_{\Omega_{[a-1,b+1]} \setminus \Omega_{[a,b]}} |\nabla \varphi_{L}|^{2} dx + C_{3} \int_{\Omega_{[a-1,b+1]} \setminus \Omega_{[a,b]}} |\hat{\phi}|^{2} dx.
\]
Notice that,
\[
\int_{\Omega_{[a-1,b+1]}} |\hat{\phi}|^2 dx = \int_{\Omega_{[a-1,a]}} |\hat{\phi}|^2 dx + \int_{\Omega_{[b+1,b+1]}} |\hat{\phi}|^2 dx = \int_{\Omega_{[a-1,a]}} |\hat{\phi}_L(x) - P_{[a-1,a]}(\hat{\phi}_L)|^2 dx + \int_{\Omega_{[b+1,b+1]}} |\hat{\phi}_L(x) - P_{[b+1,b+1]}(\hat{\phi}_L)|^2 dx \leq C_4 \int_{\Omega_{[a-1,a]}} |\nabla \hat{\phi}_L(x)|^2 dx + C_4 \int_{\Omega_{[b+1,b+1]}} |\nabla \hat{\phi}_L(x)|^2 dx = C_4 \int_{\Omega_{[a-1,b+1]}} |\nabla \hat{\phi}_L(x)|^2 dx.
\]
(4.13)

Then, taking \( \nu = \frac{\lambda}{2} \), we have
\[
\frac{\lambda}{2} \int_{\Omega_{(a,b)}} |\nabla \hat{\phi}_L(x)|^2 dx \leq \int_{\Omega_{(a-1,b+1)}} \eta^2 \rho^\varepsilon |\nabla \hat{\phi}_L(x)|^2 dx - \frac{\lambda}{2} \int_{\Omega_{(a,b)}} |\nabla \hat{\phi}_L(x)|^2 dx \leq C_5 \int_{\Omega_{(a-1,b+1)}} |\nabla \hat{\phi}_L(x)|^2 dx + C_6 \int_{\Omega_{(a-1,b+1)}} |\nabla \hat{\phi}_L(x)|^2 dx \leq C_5 \int_{\Omega_{(a-1,b+1)}} |\nabla \hat{\phi}_L(x)|^2 dx + C_7 (b - a + 2)m^2 \quad (4.14)
\]
where we have used (4.4) for the last inequality. From (4.14), we further have that
\[
\int_{\Omega_{(a,b)}} |\nabla \hat{\phi}_L(x)|^2 dx \leq \frac{C_5}{C_5 + \frac{\lambda}{2}} \int_{\Omega_{(a-1,b+1)}} |\nabla \hat{\phi}_L(x)|^2 dx + \frac{C_7}{C_5 + \frac{\lambda}{2}} (b - a + 2)m^2 \quad (4.15)
\]
Set
\[
B_{a,b} = \frac{1}{b - a} \int_{\Omega_{(a,b)}} |\nabla \hat{\phi}_L(x)|^2 dx,
\]
It follows from (4.15) that
\[
B_{a,b} \leq \frac{b - a + 2}{b - a} \frac{C_5}{C_5 + \frac{\lambda}{2}} B_{a-1,b+1} + \frac{C_7}{C_5 + \frac{\lambda}{2}} \frac{b - a + 2}{b - a} m^2.
\]

Now, we take \( l < b - a \) such that \( \frac{b - a}{b - a} \frac{C_5}{C_5 + \frac{\lambda}{2}} \) \( \leq \vartheta_0 < 1 \). Then, for any \( -\frac{b}{2} < a < 1 \)
\( a < b < b + 1 < \frac{b}{2} \), we have
\[
B_{a,b} \leq \vartheta_0 B_{a-1,b+1} + C_8 m^2,
\]
where \( C_8 \) is uniformly bounded. Hence, following the same argument in the proof of Lemma 4.2 to obtain (4.4), we have [4.10].

**Lemma 4.5.** Assume (2.1) holds, then there are constants \( 0 < \alpha < 1 \) and \( C \) independent of \( L \), for any \( b - a > l \) and \( \Omega_{(a-1,b+1)} \subset \Omega_{\frac{b}{2}} \), such that for any solution \( \hat{\phi}_L(x) \in H_L \) of Problem C4 (\( m, L \)),
\[
\sup_{x \in \Omega_{(a,b)}} |\nabla \hat{\phi}_L(x)| \leq C m^2,
\]
and
\[
\sup_{x,y \in \Omega_{(a,b)}} |\nabla \hat{\phi}_L(x) - \nabla \hat{\phi}_L(y)| \leq C m^2.
\]
In order to prove Lemma 4.5, we need the following proposition.

**Proposition 4.2.** Let $a_{ij}^l$ for $i, j = 1, \ldots, n$ be $L^\infty$ functions on $B_1$, and $\lambda$ be a positive constant. Assume that

$$\forall \xi \in \mathbb{R}^n, \lambda|\xi|^2 \leq \sum_{i,j=1}^n a_{ij}^l \xi_i \xi_j \leq \lambda^{-1}|\xi|^2,$$

and $f_i^l \in L^q$, $q > n$.

Let $w(x)$ be a function in $H^1$. Let $f_i^l$ be functions in $L^q$ with $q > n$. Suppose

$$\sum_{i,j=1}^n \partial_i \left[ a_{ij}^l(x) \partial_j w(x) \right] + \sum_{i=1}^n \partial_i f_i^l = 0$$

holds in the distribution sense. Then $w(x)$ is Hölder continuous in $B_{1/2}$ and there exist two constants $0 < \alpha \leq 1$, $k$, depending on $\lambda$ such that

$$\sup_{x \in B_{1/2}} |w(x)| \leq k \left( ||w||_{L^2(B_1)} + ||f_i^l||_{L^q(B_1)} \right),$$

$$\sup_{x,y \in B_{1/2}} \frac{|w(x) - w(y)|}{|x - y|^\alpha} \leq k \left( ||w||_{L^2(B_1)} + ||f_i^l||_{L^q(B_1)} \right).$$

The proof of this proposition can be found in [23] (see Theorem 8.24).

Based on Proposition 4.2, we can show the $C^{1,\alpha}$-regularity of $\nabla \phi_L^{(\epsilon)}$, which is Lemma 4.5.

**Proof.** Let $\Phi = \partial_k \phi_L^{(\epsilon)}$, $\phi' = \partial_k \phi_L$ for $k = 1, \ldots, n$. Then by the straightforward calculation, $\Phi$ satisfies

$$\sum_{i,j=1}^n \partial_i (a_{ij} \partial_j \Phi) + \sum_{i=1}^n \partial_i (b \partial_i \phi^{(\epsilon)}) + \epsilon^{-2} \sum_{i,j=1}^n \partial_i (\hat{a}_{ij} \partial_j \phi') = 0.$$

Since $\Delta \phi_L = 0$, $\Delta \phi' = 0$. We can change the equation above to:

$$\sum_{i,j=1}^n \partial_i \left( \hat{a}_{ij} \partial_j \Phi \right) = -\epsilon^{-2} \sum_{i,j=1}^n \partial_i ((\hat{a}_{ij} - \delta_{ij}) \partial_j \phi') - \sum_{i=1}^n \partial_i (\hat{b} \partial_i \phi^{(\epsilon)}).$$

Here, we introduce

$$f_{ij} = \epsilon^{-2} (\hat{a}_{ij} - \delta_{ij})$$

$$= \frac{\hat{b}^{(\epsilon)} - 1}{\epsilon^2} \delta_{ij} - \epsilon^{-2} \frac{\hat{q} \Lambda (|\nabla \phi^{(\epsilon)}|^2, \phi) \partial_i \phi^{(\epsilon)} \partial_j \phi^{(\epsilon)}}{(|\phi|)^2},$$

then,

$$\epsilon^{-2} \sum_{i,j=1}^n \partial_i ((\hat{a}_{ij} - \delta_{ij}) \partial_j \phi') = \sum_{i=1}^n \partial_i (\sum_{j=1}^n f_{ij} \partial_j \phi'),$$

(4.16)
Now we are going to show the uniform $L^\infty$ estimate of $f_{ij}$. For the first term,
\[ \frac{\hat{\rho}^s - 1}{\varepsilon^2} = \frac{\hat{\rho}^s (|\nabla \varphi^{(s)}|^2, \phi) - 1}{\varepsilon^2} = \frac{\tilde{h}^{-1} \left( -\frac{\varepsilon^2 \hat{q}(|\nabla \varphi^{(s)}|^2, \phi)}{2} + \tilde{h}(1) \right) - 1}{\varepsilon^2} = \frac{\tilde{h}^{-1} \left( -\frac{\varepsilon^2 \hat{q}(|\nabla \varphi^{(s)}|^2, \phi)}{2} + \tilde{h}(1) \right) - \tilde{h}^{-1}(h(1))}{\varepsilon^2} = \frac{-\hat{q}(|\nabla \varphi^{(s)}|^2, \phi) \int_0^1 \left( \tilde{h}^{-1}' \left( -t \varepsilon^2 \hat{q}(|\nabla \varphi^{(s)}|^2, \phi) + \tilde{h}(1) \right) \right) dt \ (4.18)}{\varepsilon^2} \]

For the second term,
\[ \varepsilon^{-2} \frac{\hat{q}_A(|\nabla \varphi^{(s)}|^2, \phi) \partial_i \varphi^{(s)} \partial_j \varphi^{(s)}}{(c^s)^2} = \frac{\hat{q}_A(|\nabla \varphi^{(s)}|^2, \phi) \partial_i \varphi^{(s)} \partial_j \varphi^{(s)}}{\hat{p}'(\rho^s)}. \ (4.19) \]

Therefore, due to the cut-off, we have that the uniform $L^\infty$ estimate of $f_{ij}$.

Also, for $i, k = 1, \cdots, n$,
\[ \left| \hat{b}_k \partial_i \varphi^{(s)} \right| \leq C |\partial_k \phi|. \ (4.20) \]

By $\nabla \psi \in L^q$, we can show $\hat{b}_k \partial_i \varphi^{(s)}$ are bounded in $L^q$ for $q > n$.

By employing Proposition 4.2, Lemma 4.4 leads to the interior estimate of $\phi$, which conclude the uniformly $L^\infty$ and Hölder continuous estimates.

Next for the boundary estimate near $\partial \Omega$, one can apply Theorem 8.29 in [23] to replace Proposition 4.2 to follow the arguments above to show the boundary estimates near $\partial \Omega_L$.

\[ \square \]

4.3. Existence of solutions of Problem I1 (m) and Problem C2 (m). Based on the local average lemmas obtained from the previous subsections, we can pass the limit for $(\bar{\varphi}_L, \bar{\varphi}^{(s)}_L)$ as $L \to \infty$ to obtain the existence of solutions of Problem I1 (m) and Problem C2 (m).

For any fixed suitably large $L$, according to previous subsections, one can get $H^1$ functions $\bar{\varphi}_L(x)$ and $\bar{\varphi}^{(s)}_L(x)$, which are the weak solution to Problem I2 (m, $L$) and Problem C3 (m, $L$) respectively. Without loss of the generality, $\bar{\varphi}_L(0) = 0$ and $\bar{\varphi}^{(s)}_L(0) = 0$. Moreover, Lemma 4.3 and Lemma 4.5 showed $\bar{\varphi}_L \in C^{1,\alpha}(\overline{\Omega}/2)$ and $\bar{\varphi}^{(s)}_L \in C^{1,\alpha}(\overline{\Omega}/2)$ with
\[ \| \bar{\varphi}_L \|_{C^{0,\alpha}(\Omega/2)} \leq Cm^2, \quad \text{and} \quad \| \bar{\varphi}^{(s)}_L \|_{C^{0,\alpha}(\Omega/2)} \leq Cm^2. \]

Also, for any $\eta \in C_0^\infty(\Omega_L)$, we have
\[ \int_{\Omega} \nabla \bar{\varphi}_L \cdot \nabla \eta dx = 0 \quad \text{and} \quad \int_{\Omega} \hat{\rho}^s(|\nabla \varphi^{(s)}_L|^2, \phi) \nabla \varphi^{(s)}_L \cdot \nabla \eta dx = 0, \]
where $\varphi^{(s)}_L = \bar{\varphi}_L + \varepsilon^2 \bar{\varphi}^{(s)}_L$. For the mass flux condition,
\[ \int_{S_0} \frac{\partial \bar{\varphi}_L}{\partial n} ds = m \quad \text{and} \quad \int_{S_0} \hat{\rho}^s \left( |\nabla \varphi^{(s)}_L|^2, \phi \right) \frac{\partial \varphi^{(s)}_L}{\partial \nu} ds = m, \]
where $S_0$ is an arbitrary cross section of $\Omega_L$, $l$ are the unit outer normals of $S_0$. 
By a standard diagonal argument, there exist functions \( \bar{\varphi} \in C^{1,\alpha}(\Omega) \) and \( \bar{\varphi}^{(e)} \in C^{1,\alpha}(\Omega) \) with the subsequences \( \bar{\varphi}_{L_n} \) and \( \bar{\varphi}^{(e)}_{L_n} \) such that for any \( K \), for some \( \alpha' < \alpha \), \( \bar{\varphi}_{L_n} \to \bar{\varphi} \) and \( \bar{\varphi}^{(e)}_{L_n} \to \bar{\varphi}^{(e)} \) in \( C^{1,\alpha'}(\Omega_K) \) as \( n \to \infty \). Therefore, \( \bar{\varphi} \) is the solution of Problem I1(m), and \( \varphi^{(e)} \) is the solution Problem C2(m) with \( \varphi^{(e)} = \bar{\varphi} + \varepsilon^2 \bar{\varphi}^{(e)} \).

5. Uniqueness of Solutions in the Infinity Long Nozzle

5.1. Uniqueness of incompressible flow. In this subsection, we will show the uniqueness of solutions to Problem I1(m).

Lemma 5.1. Suppose that \( \Omega \) satisfies the assumptions [2.1], and \( \bar{\varphi}_k \), \( (k = 1, 2) \) are weak solutions to the following problem

\[
\begin{align*}
\Delta \varphi_k &= 0, \quad x \in \Omega, \\
\frac{\partial \varphi_k}{\partial n} &= 0, \quad \partial \Omega,
\end{align*}
\]

(5.1)

associated with the same incoming mass flux \( m \). There exists a constant \( \bar{C} \) such that \( \|\nabla \varphi_k\|_{L^\infty} < \bar{C} \). Then

\[
\nabla \varphi_1 = \nabla \varphi_2, \quad x \in \Omega.
\]

Proof. Set \( \hat{\varphi} = \varphi_1 - \varphi_2 \). Then \( \hat{\varphi} \) satisfies

\[
\begin{align*}
\Delta \hat{\varphi} &= 0, \quad x \in \Omega, \\
\frac{\partial \hat{\varphi}}{\partial n} &= 0, \quad \partial \Omega.
\end{align*}
\]

(5.2)

Let \( \eta(x) \) be a \( C^\infty_0 \) function satisfying: \( \eta|_{\Omega(-L,L)} = 1 \), \( \eta|_{\Omega(-L-1,L+1)} = 0 \), and \( |\nabla \eta| \leq 1 \). And

\[
\hat{\psi}(x) = \begin{cases}
\hat{\varphi}(x) - \frac{1}{|\Omega(-L-1,L)|} \int_{\Omega(-L-1,L)} \hat{\varphi}(x)dx, & x \in \Omega(-L-1,L), \\
\hat{\varphi}(x) - \bar{\varphi}_L^- - \frac{\hat{\varphi}_L^- - \bar{\varphi}_L^-}{2L}(x_n + L), & x \in \Omega(-L,L), \\
\hat{\varphi}(x) - \bar{\varphi}_L^+, & x \in \Omega(L,L+1),
\end{cases}
\]

where \( \bar{\varphi}_L^- = \frac{1}{|\Omega(-L-1,L)|} \int_{\Omega(-L-1,L)} \bar{\varphi}(x)dx \), and \( \bar{\varphi}_L^+ = \frac{1}{|\Omega(L,L+1)|} \int_{\Omega(L,L+1)} \bar{\varphi}(x)dx \).

Multiplying on the both sides of the first equation in (5.2) by \( \eta^2 \hat{\psi} \), and integrating it over \( \Omega_L \), one obtains

\[
\int_{\Omega(-L-1,L+1)} \eta^2 |\nabla \hat{\varphi}|^2 dx - \frac{\hat{\varphi}_L^+ - \bar{\varphi}_L^-}{2L} \int_{\Omega(-L,L)} \eta^2 \frac{\partial \hat{\varphi}}{\partial x_n} dx = -2 \int_{\Omega(-L-1,L)} \eta(\hat{\varphi} - \bar{\varphi}_L^-) \nabla \eta \nabla \varphi dx - 2 \int_{\Omega(L,L+1)} \eta(\hat{\varphi} - \bar{\varphi}_L^+) \nabla \eta \cdot \nabla \varphi dx.
\]

(5.3)

The second term in (5.3) vanishes due to the cancellation of mass flux condition. Similar to the calculation in Lemma 4.2 we have

\[
\int_{\Omega(-L,L)} |\nabla \varphi|^2 dx \leq C_3 \int_{\Omega(-L-1,L) \cup \Omega(L,L+1)} |\nabla \varphi|^2 dx,
\]

(5.4)
where $C_3$ is independents on $L$. Then, we can have the iteration inequality:

$$
\int_{\Omega_{(-L,L)}} |\nabla \phi|^2 dx \leq \tilde{\vartheta} \int_{\Omega_{(-L-1,L+1)}} |\nabla \phi|^2 dx,
$$

(5.5)

where $\frac{C_3}{C_3+1} =: \tilde{\vartheta} < 1$ is a uniform constant. By repeating the previous argument, one can get: for $n \geq 1$

$$
\int_{\Omega_{(-L,L)}} |\nabla \tilde{\varphi}|^2 dx \leq \tilde{\vartheta}^n \int_{\Omega_{(-L-n+L+n)}} |\nabla \phi|^2 dx \leq \tilde{\vartheta}^n C_3 \int_{\Omega_{(-L-n+L-n+1)\cup \Omega_{(L+n,L+n+1)}}} |\nabla \phi|^2 dx \leq 2\tilde{\vartheta}^n \tilde{C}|S_{max}|,
$$

(5.6)

where $|S_{max}|$ denotes the maximal of the cross section of the nozzle, and we used $\|\nabla \varphi_k\|_{L^\infty} < \tilde{C}$, for $k = 1, 2$. Taking $n \to \infty$ in (5.6) yields

$$
\nabla \varphi = 0 \quad \text{in} \quad \Omega_L.
$$

Then, it yields for $x \in \Omega$, $\nabla \tilde{\varphi}_1 = \nabla \tilde{\varphi}_2$.

Based on Lemma 5.1, we can conclude the proof of Theorem 2.1.

**Proof of Theorem 2.1.** It is easy to see the existence and uniqueness of a classic solution in Theorem 2.1 follows directly from subsection 4.3 and Lemma 5.1 Moreover, it follows from Lemma 4.3 that $\bar{u} = \nabla \bar{\phi} \in (C^\alpha(\Omega))^n$. It is noticeable that $\tilde{\phi} \in W^{1,q}_0$ for $q > n$, which leads $\phi$ is in the Hölder space for some $\alpha$. By (2.4), $\bar{p} \in C^\alpha(\Omega)$.

5.2. Uniqueness of compressible flow $\phi^{(e)}$.

**Lemma 5.2.** Suppose that $\Omega$ satisfies the assumptions (2.1), and $\phi_k^{(e)}$ ($k = 1, 2$) are the solutions of Problem C2 (m), with $\|\nabla \phi_k^{(e)}\|_{L^\infty} < \tilde{C}$ Then, for $x \in \Omega$, $\nabla \phi_1^{(e)}(x) = \nabla \phi_2^{(e)}(x)$.

**Proof.** Set $\tilde{\phi}^{(e)} = \phi_1^{(e)} - \phi_2^{(e)}$. Then $\tilde{\phi}^{(e)}$ satisfies

$$
\begin{align*}
\partial_t (A_{ij} \partial_j \tilde{\phi}^{(e)}) &= 0, \quad \text{in} \quad \Omega, \\
\frac{\partial \tilde{\phi}^{(e)}}{\partial n} &= 0, \quad \text{on} \quad \partial \Omega,
\end{align*}
$$

(5.7)

where

$$
A_{ij} = \int_1^2 \left( \rho^e (|\nabla \phi_s^{(e)}|^2, \phi) \delta_{ij} + 2 \rho^e (|\nabla \phi_s^{(e)}|^2, \phi) \partial_i \phi_s^{(e)} \partial_j \phi_s^{(e)} \right) ds,
$$

with $\phi_s^{(e)} = (2-s) \phi_1^{(e)} + (s-1) \phi_2^{(e)}$. Moreover, there exist a positive constant $\lambda$, such that for any vector $\xi \in \mathbb{R}^n$

$$
\lambda |\xi|^2 < A_{ij} \xi_i \xi_j < \lambda^{-1} |\xi|^2.
$$

(5.8)

Let $\eta(x) = \eta(x_n)$ be a $C_0^\infty$ function satisfying

$$
\eta(x_n) \equiv 1 \quad \text{for} \quad |x_n| \leq L; \quad \eta(x_n) \equiv 0 \quad \text{for} \quad |x_n| \geq L + 1, \quad \text{and} \quad |\eta'(x_n)| \leq 1,
$$
For $L > 0$

\[
\hat{\phi}(x) = \begin{cases} 
\varphi^{(e)}(x) - \varphi^{(e)}_{L-}, & x \in \Omega_{(-L-1,-L)}; \\
\varphi^{(e)}(x) - \varphi^{(e)}_{L-} - \frac{\varphi^{(e)}_{L-} - \varphi^{(e)}_{L+}}{2L} (x_n + L), & x \in \Omega_{(-L,L)}, \\
\varphi^{(e)}(x) - \varphi^{(e)}_{L+}, & x \in \Omega_{(L,L+1)},
\end{cases}
\]

where

\[
\varphi^{(e)}_{L-} = \frac{1}{|\Omega_{(-L-1,-L)}|} \int_{\Omega_{(-L-1,-L)}} \varphi^{(e)}(x) dx, \quad \varphi^{(e)}_{L+} = \frac{1}{|\Omega_{(L,L+1)}|} \int_{\Omega_{(L,L+1)}} \varphi^{(e)}(x) dx.
\]

Note that $\nabla \hat{\phi} = \nabla \varphi^{(e)} = \frac{\varphi^{(e)}_{L-} - \varphi^{(e)}_{L+}}{2L} \chi_{-L,L}(x_n) \vec{e}_n$, $\vec{e}_n = (0, \cdots, 0, 1)$. Here, $\chi_{-L,L}(x_n)$ is the characteristic function of $(-L, L)$.

Multiplying on both sides of the first equation in (5.7) by $\eta^2 \hat{\phi}$, and integrating it over $\Omega$, one obtains

\[
\int_{\Omega_{(-L-1,-L+1)}} \eta^2 A_{ij} \partial_i \varphi^{(e)} \partial_j \varphi^{(e)} dx - \frac{\varphi^{(e)}_{L-} - \varphi^{(e)}_{L+}}{2L} \int_{\Omega_{(-L,L)}} \eta^2 A_{nj} \partial_j \varphi^{(e)} dx = -2 \int_{\Omega_{(-L-1,-L)}} \eta (\varphi^{(e)} - \varphi^{(e)}_{L-}) A_{ij} \partial_i \eta \partial_j \varphi^{(e)} dx + \int_{\Omega_{(-L-1,-L+1)}} \eta^2 \rho^2 (|\nabla \varphi_1^{(e)}|^2, \varphi) \nabla \varphi_1^{(e)} - \rho^2 (|\nabla \varphi_2^{(e)}|^2, \varphi) \nabla \varphi_2^{(e)}) \cdot \vec{e}_n dx.
\]

The second integral on the left hand side vanishes. Indeed,

\[
\int_{\Omega_{(-L,L)}} \eta^2 A_{nj} \partial_j \varphi^{(e)} dx = -2 \int_{\Omega_{(-L-1,-L)}} \eta^2 (|\nabla \varphi_1^{(e)}|^2, \varphi) \nabla \varphi_1^{(e)} - \rho^2 (|\nabla \varphi_2^{(e)}|^2, \varphi) \nabla \varphi_2^{(e)}) \cdot \vec{e}_n dx.
\]

since the two solutions possess the same mass flux $m$.

It follows from (5.9) and (5.8) that

\[
\lambda \int_{\Omega_{(-L,L)}} |\nabla \varphi^{(e)}|^2 dx \leq 4\lambda^{-1} \int_{\Omega_{(-L-1,-L)}} |\varphi^{(e)} - \varphi^{(e)}_{L-}| |\nabla \varphi^{(e)}| dx + 4\lambda^{-1} \int_{\Omega_{(L,L+1)}} |\varphi^{(e)} - \varphi^{(e)}_{L+}| |\nabla \varphi^{(e)}| dx \leq C \int_{\Omega_{(-L-1,-L) \cup \Omega_{(L,L+1)}}} |\nabla \varphi^{(e)}|^2 dx.
\]

where $C$ is independent of $L$. We have

\[
\lambda \int_{\Omega_{(-L,L)}} |\nabla \varphi^{(e)}|^2 dx \leq C \int_{\Omega_{(-L-1,-L) \cup \Omega_{(L,L+1)}}} |\nabla \varphi^{(e)}|^2 dx.
\]

and

\[
\int_{\Omega_{(-L,L)}} |\nabla \varphi^{(e)}|^2 dx \leq \bar{\theta} \int_{\Omega_{(-L-1,-L) \cup \Omega_{(L,L+1)}}} |\nabla \varphi^{(e)}|^2 dx,
\]

(5.12)
where \( \frac{C}{c^+} =: \bar{c} < 1 \). By repeating the previous argument, one can get: for \( n \geq 1 \)

\[
\int_{\Omega_{(-L,L)}} |\nabla \phi^{(e)}|^2 \, dx \leq \bar{c}^n \int_{\Omega_{(-L-n,L+n)}} |\nabla \phi^{(e)}|^2 \, dx
\]

\[
\leq \bar{c}^n C_3 \int_{\Omega_{(-L-n-1,L-n)} \cup \Omega_{(L-n,L+n+1)}} |\nabla \phi^{(e)}|^2 \, dx
\]

\[
\leq 2\bar{c}^n C |S_{\text{max}}|,
\]

(5.13)

where we used \( \|\nabla \phi^{(e)}_k\|_{L^\infty} < \hat{C} \), for \( k = 1, 2 \). Taking \( n \to \infty \) in (5.13) yields

\[ \nabla \phi^{(e)} = 0 \quad \text{in} \quad \Omega_L. \]

Then, it yields for \( x \in \Omega \), \( \nabla \phi^{(e)}_1 = \nabla \phi^{(e)}_2 \).

\[ \square \]

**Remark 5.1.** It is easy to see that when \( |\nabla \phi^{(e)}| < \hat{q}_\theta^0(\phi) \), \( \phi^{(e)} \) is the same solution as the one obtained in [15].

### 6. Proof of Theorem 2.2

In this section, we will conclude the proof of Theorem 2.2 by showing the solutions of Problem C2 \((m)\) are solutions of Problem C1 \((m)\), and then consider the convergent rate of the low Mach number limit.

**Proof.** Up to now, we have shown that for a given fixed cut-off parameter \( \theta \) and \( \varepsilon_0 \), there exists a unique solution of Problem C2 \((m)\), which is denoted as \( \phi^{(e)}(x; \varepsilon_0, \theta) \). It is noticeable that for a given \( \theta \in (0, 1) \), if \( |\nabla \phi^{(e)}(x; \varepsilon_0, \theta)| < \hat{q}_\theta^0(\phi) \), then \( \phi^{(e)}(x; \varepsilon_0, \theta) \) is the unique solution of Problem C2 \((m)\). Note that

\[
|\nabla \phi^{(e)}(x; \varepsilon_0, \theta)| = |\varepsilon^2 \nabla \tilde{\phi}^{(e)}(x; \varepsilon_0, \theta) + \nabla \tilde{\varphi}(x)| \leq \max |\nabla \tilde{\phi}| + C(\varepsilon_0, \theta)\varepsilon^2.
\]

(6.1)

Hence, there exists \( \varepsilon_{0,\theta} \leq \varepsilon_0 \) such that \( |\nabla \phi^{(e)}(x; \varepsilon_0, \theta)| < \hat{q}_\theta^0(\phi) \), for any \( 0 < \varepsilon < \varepsilon_{0,\theta} \). Form the definition and uniqueness of \( \phi^{(e)} \), \( \{\varepsilon_{0,\theta}\} \) is a non-decreasing sequence respect to \( \theta \) with upper bound \( \varepsilon_0 \). Then, we introduce \( \varepsilon_{0,cr} = \overline{\lim}_{0 < \theta < 1} \varepsilon_{0,\theta} \) such that for \( 0 < \varepsilon < \varepsilon_{0,cr} \), there exists a unique \( \phi(x; \varepsilon_0) \),

\[
|\nabla \phi^{(e)}(x; \varepsilon_0)| = |\varepsilon^2 \nabla \tilde{\phi}^{(e)}(x; \varepsilon_0) + \nabla \tilde{\varphi}(x)| < \hat{q}_{cr}^0(\phi),
\]

(6.2)

which equals \( M^\varepsilon(\phi) < 1 \). In this case, the cut-off can be removed such that the solution is a solution of Problem C1 \((m)\). After removing the subsonic cut-off, we want to optimise the critical \( \varepsilon_{cr} \). For each \( 0 < \varepsilon_0 < 1 \), there exists an \( \varepsilon_{0,cr} \), with \( 0 < \varepsilon_{0,cr} \leq \varepsilon_0 < 1 \). Then, the critical \( \varepsilon_c = \sup_{0 < \varepsilon_0 < 1} \varepsilon_{0,cr} \) satisfies for any \( \varepsilon \in (0, \varepsilon_c) \), \( 0 < M^\varepsilon(\phi) < 1 \), and \( |\nabla \phi^{(e)}| \) is uniform bounded respect \( \varepsilon \).

Finally, let us consider the convergence rate of the low Mach number limit. Note that \( \phi^{(e)} = \tilde{\phi} + \varepsilon^2 \tilde{\phi}(\varepsilon) \) in the Hölder space, so \( \nabla \phi^{(e)} = \nabla \tilde{\phi} + \nabla \tilde{\phi}(\varepsilon) \), which equals to

\[
u^\varepsilon = \tilde{u} + \varepsilon^2 \tilde{u}^{(e)}.
\]

(6.3)

It is noticeable that \( \phi \in W^{1,q}_{loc} \) for \( q > n \), so \( \phi \) is in some Hölder space. Therefore, for the density, by (2.13) \( \rho^{\varepsilon} \in C^\alpha(\Omega) \). Then \( \rho^{\varepsilon} \in C^\alpha(\Omega) \). By the straightforward computation like in (4.18), we have

\[
\rho^{\varepsilon} = 1 + O(\varepsilon^2).
\]

(6.4)
Consequently, the definition of the Mach number leads to $M^\varepsilon = O(\varepsilon)$. Finally, for the gradients of the pressure, we have
\[
\nabla p^\varepsilon - \nabla \bar{p} = -\text{div}(\rho^\varepsilon u^\varepsilon \otimes u^\varepsilon) + \text{div}(\bar{u} \otimes \bar{u}) + \text{div}(\rho^\varepsilon u^\varepsilon \otimes u^\varepsilon)
\]
(6.5)
From (6.3) and (6.4), we can conclude: in the weak sense,
\[
\nabla p^\varepsilon = \nabla \bar{p} + O(\varepsilon^2).
\]
(6.6)
It completes the proof of Theorem 2.2.
