ABSTRACT

Context. Molecular line surveys are among the main tools to probe the structure and physical conditions in protoplanetary disks (PPDs), the birthplace of planets. The large radial and vertical temperature as well as density gradients in these PPDs lead to a complex chemical composition, making chemistry an important step to understand the variety of planetary systems.

Aims. We aimed to study the chemical content of the protoplanetary disk surrounding GG Tau A, a well-known triple T Tauri system.

Methods. We used NOEMA with the new correlator PolyFix to observe rotational lines at ∼2.6 to 4 mm from a few dozen molecules. We analysed the data with a radiative transfer code to derive molecular densities and the abundance relative to 12CO, which we compare to those of the TMC1 cloud and LkCa 15 disk.

Results. We report the first detection of CCS in PPDs. We also marginally detect OCS and find 16 other molecules in the GG Tauri outer disk. Ten of them had been found previously, while seven others (13CN, N2+H+, HNC, DNC, HC3N, CCS, and C34S) are new detections in this disk.

Conclusions. The analysis confirms that sulphur chemistry is not yet properly understood. The D/H ratio, derived from DCO+/HCO+, DCN/HCN, and DNC/HNC ratios, points towards a low temperature chemistry. The detection of the rare species CCS confirms that GG Tau is a good laboratory to study the protoplanetary disk chemistry, thanks to its large disk size and mass.

Key words. astrochemistry – molecular data – protoplanetary disks – stars: individual: GG Tau A

1. Introduction

The chemical content in a protoplanetary disk (PPD) is thought to be a combination of parent cloud inheritances and the product of in situ reactions. PPDs are flared and layered, displaying important radial and vertical temperature and density gradients that result in a complex chemical structure and evolution. Each layer in the disk has conditions suitable for different chemical reactions, leading to different molecular abundances. For example, photo sensitive molecules such as CN and CCH are believed to probe the upper most layer which is directly irradiated by stellar UV; CO and its isotopologues arise from the layer just below it, while molecules are frozen on the dust grains (millimetre-sized) settled in the cold disk midplane. So far, more than thirty molecules have been detected in PPDs (see Phuong et al. 2018 for a list, and the more recent detections of H2CS by Le Gal et al. 2019, DNC by Loomis et al. 2020, SO by Rivière-Marichalar et al. 2020, and SO2 by Booth et al. 2021).

In this Letter, we report the first deep survey of a PPD covering the 2.6 to 4.2 mm window, where fundamental transitions of most simple molecules occur. We observed the GG Tau A system with the NOEMA interferometer. GG Tau A is a triple T Tauri system (AA-Ab1/b2) with respective separations of 35 and 4.5 au (Di Folco et al. 2014), located in the Taurus-Auriga star forming...
region (150 pc, Gaia Collaboration 2018). It is surrounded by a large and massive Keplerian circumbinary (or ternary) disk with an estimated mass \((M_{\text{disk}} = 0.15 M_\odot)\) using dust properties that are typically assumed for PPDs. The disk consists of a dense, narrow (radius from \(~180\) to \(260\) au) ring that contains 70% of the disk mass. Beyond the ring, the outer gas disk extends out to \(~800\) au. The temperature profile of the disk has been studied by Dutrey et al. (2014a), Guilhouet al. (1999), and Phuong et al. (2020); the dust temperature is 14 K at 200 au, and the kinetic temperature derived from CO analysis is \(\sim\)25 K at the same radius. The large size, low temperature, and large mass make GG Tau A disk an ideal laboratory to study cold molecular chemistry.

We present the observations and results in Sect. 2. Data analysis using the radiative transfer code DiskFit is presented in Sect. 3. We then discuss the results in Sect. 4.

2. Observations and results

2.1. Observations

Observations were carried out using the NOEMA array between Sep. 2019 and Apr. 2020 (Projects S19AZ and W19AV). Four frequency setups were used to cover the frequency range \(70.5–113.5\) GHz. The PolyFix correlator covered the full bandwidth of \(~15\) GHz at 2 MHz resolution (\(~6.5\) km s\(^{-1}\)) while the total line width of GG Tau A is around \(3.5\) km s\(^{-1}\), see Fig. 1], plus a large number of spectral windows with a \(62.5\) kHz channel spacing (resolution \(0.2–0.3\) km s\(^{-1}\), comparable to the local thermal linewidth in GG Tau), optimised to cover a maximum number of spectral lines. The phase calibrators used were J0440+146 and 0507+179. Flux calibration was done using MWC349 and LkHa101. The standard pipeline in the CLIC package was used for calibration, with minor data editing. Three setups covering [70.5–78; 86–93.5], [80.5–88; 96–103.5], and [90.5–98; 106.3–113.5] GHz used the C and D configuration, while the band [88.8–96.5; 104.3–112] used the C and A configuration, providing enhanced sensitivity and angular resolution in the overlapping frequencies. In total, we covered at high spectral resolution of 70 rotational lines of 38 molecular species.

2.2. Data reduction and imaging

We used the IMAGER\(^1\) interferometric imaging package to produce images. Continuum removal was carried out by the subtraction of a zero-order frequency baseline for each visibility in the \(uv\) plane. Various combinations of natural or robust weightings were used in the image processing to highlight the image properties. Beam sizes and sensitivities are summarised in Table 1 for all of the detected molecules. We note that HCN and CCS have faint lines coming from similar rotational levels and similar line strengths: to illustrate their detection, lines from each molecule were stacked in velocity to produce a single data set. As synthesised beams exhibit significant sidelobes, deconvolution was done using the Hogbom method down to the rms noise. Integrated spectra are shown in Fig. 1, and moment 0 maps are shown in Figs. 2 and 3. To further enhance the S/N, we used the Keplerian deprojection technique using kinematics and geometrical parameters from Dutrey et al. (2014a), see Table 2. The images are deprojected and the velocities were corrected from the rotation pattern, thereby bringing all signals to the systemic velocity (see Teague et al. 2016; Yen et al. 2016). The resulting spectra and radius-velocity (RV) diagrams are shown in Figs. 4 and E.1. The ‘teardrop’ pattern (Teague 2019) expected for Keplerian disks transformed into ‘Eiffel tower’-like plots, because of the lack of emission from the tidal cavity of GG Tau A. Radial profiles of the line peak brightness are displayed in Appendix C.

2.3. Results

Among the 38 molecules which were observed in the survey, 17 are detected, including \(^{13}\)CO and C\(^{18}\)O, which we do not present in this Letter. The high resolution maps of these two molecules can be found in Phuong et al. (2020).

\(^1\) https://imager.oasu.u-bordeaux.fr/
The CN, HCN, HNC, HCO\(^+\), CS, N\(_2\)H\(^+\), and CCH lines were detected at high S/N, as it can be seen in Fig. 2. All lines appear optically thin, as illustrated by the hyperfine ratios of HCN, CN, CCH, and N\(_2\)H\(^+\) (see Fig. E.1), and also by the peak brightness of HCO\(^+\) (5.5 K).

Some molecules observed with a sufficiently high angular resolution (HCO\(^+\), HCN, and N\(_2\)H\(^+\)) display a clear east-west asymmetry. In a tilted Keplerian disk, the maximum opacity was obtained along the major axis, resulting in two symmetric peaks. The observed asymmetry is most obvious in HCO\(^+\), suggesting that it is related to the ‘hot spot’ detected at PA 120\(^\circ\) (Dutrey et al. 2014a; Tang et al. 2016; Phuong et al. 2020). Furthermore, CCH may also be enhanced there, while the HNC map suggests a (marginal) deficit at this position.

The apparent peak towards GG Tau for CN and CS emission is due to the lower angular resolution of these data. Their RV diagrams (Figs. 4 and E.1) clearly show that no emission is coming from inside about 200 au.

As is shown in Figs. 2–4, H\(^{13}\)CO\(^+\), para-H\(_2\)CO, HC\(_2\)N, and C\(^{18}\)S molecules have been detected with moderate S/N. The RV diagrams show that H\(^{13}\)CO\(^+\) and N\(_2\)H\(^+\) are more prominent in the dense ring, while CCH and H\(_2\)CO come only from the outer disk, beyond 300 au out to about 600 au (see Fig. E.1). The non-detection of the o-H\(_2\)CO \(\ell_1(5)-\ell_1(6)\) transition is consistent with the expected temperature and an ortho-para ratio of 3.

The DNC, \(^{13}\)CS, \(^{13}\)CN, and CCS lines have been detected at low S/N (\(-6\)–\(-8\sigma\)). Since the data are very noisy, in Fig. 4, we have chosen to only present their integrated spectra (top) and the RV diagram (bottom) obtained after Keplerian velocity correction, which best illustrate the detectability.

Regarding the undetected molecules list, we may have marginal detections (~2–3\(\sigma\)) of OCS, and perhaps DCO\(^+\) and DCN. However, could not detect \(^{13}\)C\(^{17}\)O, N\(_3\)D\(^+\), H\(^{13}\)CN, HC\(^{15}\)N, H\(_3\)N\(^+\), H\(_{15}\)NC, HOC\(^+\), HC\(_{18}\)N\(^+\), HCCCHO, SO, SO\(_2\), H\(_2\)CS, SiO, CCD, HDO, D\(_2\)CO, c-C\(_3\)H\(_2\), or CH\(_3\)CN molecules.

### 3. Radiative transfer modelling with DiskFit

The data were compared in the \(uv\)-plane with visibilities predicted for a disk model using the radiative transfer code DiskFit (Piétu et al. 2007). A description of DiskFit usage for GG Tau can be found in the appendix of Phuong et al. (2020).

The geometric parameters (inclination, orientation) and the physical power laws (velocity and temperature), derived from previous papers, are given in Table 2. As in Phuong et al. (2018), we kept the velocity and temperature laws as well as the power index \(p = 1.5\) of the molecular surface density fixed. Only \(\Sigma_{250}\), the value of the molecular surface density at 250 au, was left free and varied during the minimisation process.

We assumed that all molecules, except sulphur-bearing species, arise from the same layer as CO, so that they share the same temperature profile, \(T(r) = 25\ (r/200\ au)^{-1.0}\ K\). Following Dutrey et al. (2017) on the Flying Saucer edge-on disk, CS arises from the lower part of the molecular layer, closest to the disk midplane. We thus decided to analyse sulphur-bearing species with a lower temperature, namely the temperature profile

---

**Table 2. GG Tau parameters.**

| Geometry     | Law        |
|--------------|------------|
| Inclination  | \(35^\circ\) |
| Orientation  | \(T = T_0 \left(\frac{r}{r_0}\right)^{-1.0}\) |
| Systemic velocity | 6.4 km s\(^{-1}\) |
|              | \(\Sigma(r) = \Sigma_{250} \left(\frac{r}{r_0}\right)^{-1.5}\) |

**Notes.** The inner and outer radii are 180 and 600 au for detected molecules, respectively, and 800 au for undetected molecules.
Table 3. Molecular surface density at 250 au derived with DiskFit.

| Molecules | Surface density (cm⁻²) | Molecules | Surface density (cm⁻²) |
|-----------|------------------------|-----------|------------------------|
| ¹²CO      | 1.10 × 10¹⁵           | CS        | (2.6 ± 0.03) × 10¹⁵   |
| C⁵⁰⁴⁰     | 2.42 × 10¹⁰           | ¹²¹⁴CO   | (1.5 ± 0.02) × 10¹²   |
| CN        | <1.2 × 10¹¹           | Ccts      | <8.2 × 10¹⁰           |

| HCN⁻²¹⁷   | <2.9 × 10¹¹           | BD        | <1.9 × 10¹⁰           |
| HNC       | 3.4 ± 0.03 × 10¹²     | DNC       | (2.7 ± 0.7) × 10¹¹    |
| HN²⁺⁰⁺    | <1.7 × 10¹¹           | DCO       | <1.6 × 10¹⁰           |
| HCO⁺      | (1.50 ± 0.01) × 10¹⁷  | DCO⁺      | (2.2 ± 0.7) × 10¹¹    |
| H¹⁳⁰⁰C⁺    | (4.0 ± 0.2) × 10¹¹    | p-H₂CO⁺   | (3.6 ± 0.2) × 10¹²    |
| HOC⁺      | <3.2 × 10¹²           | c-H₂CO⁺   | <1.0 × 10¹²           |
| HCNH⁺     | <2.2 × 10¹³           | HCN⁺      | (5.4 ± 1.1) × 10¹¹    |
| HCCCHO    | <1.4 × 10¹⁷           | CH₂CN     | <2.5 × 10¹¹           |
| C⁴⁸⁰⁸⁸⁺    | (1.0 ± 0.1) × 10¹²    |

Notes. The temperature uncertainty only affects the derived densities by factors smaller than 2. D = detected, U = undetected, and M = marginal detected Tₗₐₜ = 15 K for S-bearing species, and Tₗₐₜ = 25 K for all other molecules. The values are taken from Phuong et al. (2020).

4. Discussion

4.1. Sulphur in protoplanetary disk: First detection of CCS

Beyond CS, only a few S-bearing species observed in molecular clouds are detected in disks: H₂S (Phuong et al. 2018), H₂CS (Le Gal et al. 2019), SO (Rivière-Marichalar et al. 2020), and SO₂ (although in a very atypical, warm disk, Booth et al. 2021).

In the GG Tau ring, we detected CCS, ¹²CS, and ¹³CS but failed to detect H₂CS, SO, and SO₂. Though OCS may be marginally detected, however (see appendix).

The CCS surface density measured in the GG Tau ring, (1.5 ± 0.2) × 10¹² cm⁻², is of the order of the best previously reported upper limits in TTS and HAe disks. Using the IRAM array, Chapillon et al. (2012) reported upper limits (at 300 au) of (0.9−1.4) × 10¹² cm⁻² in LkCa 15, GO Tau, DM Tau, and MWC 480 disks, while Le Gal & MAPS Collaboration (2021) through the ALMA Large Program Maps, obtained limits...
in the range $10^{12}$–$10^{13}$ cm$^{-2}$ for IM Lup, GM Aur, AS 209, HD 163296, and MWC 480 disks. It is also consistent with our previous upper limit of $<1.7 \times 10^{12}$ cm$^{-2}$ in GG Tau (Phuong et al. 2018).

Using Nautilus, a three phase gas-grain chemical model (Ruaud et al. 2016), Phuong et al. (2018) modelled the chemistry in the GG Tau ring. They predicted a CCS surface density of $7.2 \times 10^{10}$ cm$^{-2}$ at 250 au, a factor 20 lower than the observed value. Our new upper limits of SO and SO$_2$ are comparable with the previous ones and are still in reasonable agreement with the chemical model presented in Phuong et al. (2018). This model is also compatible with our detection of HC$_3$N, which was not detected by Phuong et al. (2018). However, for H$_2$S, Phuong et al. (2018) predicted a surface density of $3.4 \times 10^{11}$ cm$^{-2}$ a factor 100 larger than what was observed. They conclude that H$_2$S is likely transformed in more complex species at grain surfaces, precluding any thermal desorption. The failure to predict CCS further supports the idea of an incomplete handling of the complex sulphur chemistry in disk chemical models, in addition to the difficulty of estimating the amount of sulphur depletion in refractory materials in grains prior to disk formation.

4.2. Comparison with TMC1 and LkCa15

Table 4 is a comparison of molecular abundances relative to $^{13}$CO with the TMC1 dark cloud and the transition disk (cavity of radius 50 au) Piétu et al. (2007) of LkCa 15, a T Tauri star with a disk mass $\sim 0.028 M_\odot$ (Guilloteau et al. 2011). For GG Tau A, we used a $^{13}$CO column density of $\Sigma_{^{13}CO} = 1.1 \times 10^{16}$ cm$^{-2}$ (Phuong et al. 2020), while for LkCa 15 we used $\Sigma_{^{13}CO} \approx 3.6 \times 10^{15}$ cm$^{-2}$ (Piétu et al. 2007).

For TMC-1, we used $\sim 1.1 \times 10^{16}$ cm$^{-2}$, following Cernicharo et al. (2021). Relative abundances were then calculated using different studies. At first order, these abundances (and the observed D/H ratios, see Appendix A) suggest that the GG Tau and LkCa 15 disks share similar chemical properties. We note however that the radical abundances (CN and CCH) are much less abundant than in molecular clouds.

Phosphorus starts with the S$^+$ ion, while Le Gal et al. (2019) found 0.015 in LkCa 15. and somewhat higher than the value reported in TMC1 (Ruaud et al. 2016), indicating the idea of an incomplete handling of the complex sulphur chemistry in molecular clouds, while the third route $\text{CS} \rightarrow \text{CCS}$ via several reactions (Vastel et al. 2018; Semenov et al. 2018). In the outer region of a protoplanetary disk, the sulphur chemistry starts with the S$^+$ ion, the least efficient formation route of CCS. This probably makes the molecule in PPDS much less abundant than in molecular clouds.

The angular resolution of these data is insufficient for proper comparisons with a chemical model and the determination of radial variations, although physical conditions in the dense ring and the outer disk are known to be different (Phuong et al. 2020). Such comparisons would require high angular resolution images, but this is a challenging task given the low frequencies at which heavy molecules such as CCS or OCS have their peak emission at temperatures of 15–25 K or below. Nevertheless, the detection of a new rare species, CCS, in the dense ring of GG Tau confirms it is a good laboratory to study the cold PPD chemistry, thanks to its large size and mass.

Appendix A: Deuterated species

All D/H ratios (Fig. A.1) are very similar (within the error bars) and around 0.01-0.05. As already quoted by several studies, such values are in agreement with dark cloud measurements and consistent with a low temperature chemistry (e.g. Phuong et al. 2018; van Dishoeck et al. 2003; Bergin et al. 2013; Dutrey et al. 2014b; Huang et al. 2017; Aikawa et al. 2018).

Fig. A.1. D/H ratios in TMC-1, LkCa 15, and GG Tau A.

Appendix B: Molecular surface density derived with power index of $p = 1.0$ for surface density law

Table B.1. Molecular surface density at 250 au assuming $p = 1$.

| Molecules | Surface density $(\text{cm}^{-2})$ | Molecules | Surface density $(\text{cm}^{-2})$ |
|-----------|----------------------------------|-----------|----------------------------------|
| $^{13}$CO D | $1.10 \times 10^{16}$ | CS D | $(1.97 \pm 0.02) \times 10^{13}$ |
| $^{13}$C$^{18}$O D | $2.42 \times 10^{15}$ | $^{13}$CS D | $(2.0 \pm 0.5) \times 10^{13}$ |
| $^{13}$C$^{17}$O U | $< 2.1 \times 10^{13}$ | CCS D | $(9.0 \pm 0.5) \times 10^{13}$ |
| CN D | $(7.0 \pm 0.2) \times 10^{13}$ | OCS M | $(1.3 \pm 0.4) \times 10^{13}$ |
| $^{13}$CN D | $(2.1 \pm 0.8) \times 10^{12}$ | $p/\text{o-} \text{H}_2$CS U | $< 7.3 \times 10^{12}/3.7 \times 10^{12}$ |
| CCH D | $(5.0 \pm 0.1) \times 10^{11}$ | SO U | $< 2.8 \times 10^{12}$ |
| $^{13}$NH$^+$ D | $(8.4 \pm 0.7) \times 10^{11}$ | SO$_2$ U | $< 1.9 \times 10^{12}$ |
| $^{13}$ND$^+$ U | $< 2.0 \times 10^{10}$ | SiO U | $< 3.3 \times 10^{11}$ |
| HCN D | $(4.89 \pm 0.03) \times 10^{12}$ | DCN M | $(1.2 \pm 0.8) \times 10^{13}$ |
| $^{13}$HCN U | $< 1.1 \times 10^{11}$ | CCD U | $< 7.35 \times 10^{13}$ |
| $^{13}$HC$^{15}$N U | $< 2.0 \times 10^{11}$ | HDO U | $< 2.2 \times 10^{11}$ |
| HNC D | $(2.47 \pm 0.02) \times 10^{12}$ | DNC D | $(2.0 \pm 0.5) \times 10^{13}$ |
| $^{13}$HN$^{13}$C U | $< 1.3 \times 10^{11}$ | D$_2$CO U | $< 2.5 \times 10^9$ |
| HCO$^+$ D | $(1.10 \pm 0.03) \times 10^{13}$ | DCO$^+$ M | $(1.6 \pm 0.5) \times 10^{13}$ |
| $^{13}$H$^{15}$CO$^+$ D | $(2.8 \pm 0.2) \times 10^{11}$ | $p$-$\text{H}_2$CO D | $(2.6 \pm 0.1) \times 10^{12}$ |
| HOC$^+$ U | $< 1.9 \times 10^{10}$ | c-C$_3$H$_2$ U | $< 9.7 \times 10^{11}$ |
| HCNH$^+$ U | $< 1.5 \times 10^{13}$ | HC$_3$N D | $(3.5 \pm 1.2) \times 10^{13}$ |
| HCCCHO U | $< 1.3 \times 10^{17}$ | CH$_3$CN U | $< 2.2 \times 10^{11}$ |
| C$^{15}$S D | $(7.7 \pm 0.8) \times 10^{11}$ | |

Notes. D=detected, U=undetected, and M=marginal detected $T_0 = 15$ K for S-bearing species, and $T_0 = 25$ K for all other molecules. *The values are taken from Phuong et al. (2020).

Appendix C: Radial profiles

Fig. C.1. Radial profiles of brightness temperature at systemic velocity of 6.4 km s$^{-1}$ of molecular lines detected at SNR > 5.

Appendix D: Radial-velocity diagram of OCS

Fig. D.1. Integrated spectra (top) and radial-velocity diagram (bottom) of OCS obtained after making a Keplerian velocity correction and line stacking.
Appendix E: Radial-velocity diagrams of other detected molecules

![Figures showing integrated spectra and radial-velocity diagrams of various molecules including CN, HCO$^+$, HCN, N$_2$H$^+$, HNC, CCH, H$_2$CO, and HCN (with Gaussian fits, including hyperfine structure when needed, in red). The values indicate the fit results. Bottom: Corresponding radial-velocity diagram obtained after making Keplerian velocity correction and line stacking.](image-url)
