The Archetypal Homoleptic Lanthanide Quadruple-Decker—Synthesis, Mechanistic Studies, and Quantum Chemical Investigations

Luca Münzelfeld, Adrian Hauser, Pauline Hädinger, Florian Weigend,* and Peter W. Roesky*

Dedicated to Professor Glen B. Deacon on the occasion of his 85th birthday

Abstract: Reduction of [SmIII(COT1,4-SiPr3)(BH4)(thf)] (COT1,4-SiPr3 = 1,4-(Pr3Si)3C8H6) with KC8 resulted in [SmIII/II/III(COT1,4-SiPr3)]4, the first example of a homoleptic lanthanide quadruple-decker. As indicated by an analysis of the bond metrics in the solid-state, the inner Sm ion is present in the divalent oxidation state, while the outer ones are trivalent. This observation could be confirmed by quantum chemical calculations. Mechanistic studies revealed not only insight into possible formation pathways of [SmIII/II/III(COT1,4-SiPr3)]4 but also resulted in the transformation to other mixed metal sandwich complexes with unique structural properties. These are the 1D-polymeric chain structured [KSmIII(COT1,4-SiPr3)]2, the first example of a homoleptic lanthanide quadruple-decker described in this work.

The synthesis and structural characterization of ferrocene [FeCp2] (Cp = C5H5) marked the beginning of a new era in modern organometallic chemistry 70 years ago. Thereafter, sandwich complexes became widely used materials in all kinds of different fields ranging from basic research to industrial applications, fueling the quest for new synthetic approaches towards ever new compounds with striking properties and structural features. In the course of this development, different cyclic, planar and π-conjugated ligands with ring sizes from 4–9 carbon atoms varying peripheral substitution patterns and heteroatom incorporation were successfully employed to stabilize classical sandwich as well as multiple-decker sandwich complexes. Especially in the case of d-element and also f-element sandwich complexes heterocyclic ring systems like boranes or carboranes as well as purely inorganic systems such as Pr8 (Pr = P, As, Sb) and P4 rings have facilitated the synthesis of different multi-decker compounds. Together with their exclusively carbon ligand-based analogues, these have been subject to intense research. The interest in the compounds ranges from structural aspects to application approaches such as nano wires. Numerous multiple-decker complexes have been reported all over the periodic table starting with [M(Cp)] (M = Li, Na, K) s-block poly-decker assemblies over classical d-metal triple-decker complexes like the archetypal [NiII(Cp)][BF4] to p-block species as the cationic [Sn2-(Cp*)]3[Ca(C2F5)3] (Cp* = C5Me5) triple-decker. However, well-defined neutral and homoleptic (same metal, same ligand) all-carbon-based quadruple-decker complexes are to the best of our knowledge unknown.

In 4f-element chemistry sandwich complex (e.g. [LnIII(COT)]) : Scheme 1, I) and multiple-decker chemistry is considerably underdeveloped and essentially limited to COT (COT = C8H8) derivatives as bridging ligand. Typical examples are the heteroleptic [LnII(COT)(Cp)]3 (Ln = Sm, Eu, Yb) the bent and asymmetric [[(COT)LaIII(COT)LaIII(COT)LaIII][BF4]4] (La = La, Ce, Nd, Er) and [LnIII(COT)3] (Scheme 1, II). COT+ = 1,4-(Me3Si)3C8H6; Ln = La, Ce, Nd, Sm, Tb, Ho, Er, Tm, Lu) triple-decker compounds, as well as one example of a heteroleptic quadruple-decker [CrII(YbIII)3(COT)2]? (COT+) = 1,3,6-(Me3Si)3C8H6. [13]
Aside from these homometallic species, mixed metallic Ln-K quadruple-deckers of the type \([\text{K}_2(\text{thf})_2\text{Ln}_{3n/2}(\text{COT})_n]\) (Ln = Gd, Er)\(^{[14]}\) have been isolated. Additionally, homoleptic \([\text{Ln}_{3n/2}(\text{COT})_n]\) \((\text{Ln} = \text{Sc, Y, La, Ce, Nd, Eu, Tb, Ho, Tm, Yb); up to n = 30 for Eu}\); \(m = n, n-1, n+1\) poly-decker compounds have been extensively studied as molecular nanowires. However, these species, which are usually prepared by combination of laser vaporization and molecular beam methods as a mixture of compounds are not accessible as well-defined species via standard synthetic methods.\(^{[15]}\) Note, complexes ligated by nitrogen-based macrocycles like tetraphenylporphinates are not considered as sandwich complexes from a classical point of view, as they do not have planar and \(\pi\)-conjugated aromatic ligands and do not feature Ln–C bonds.\(^{[16]}\)

Despite decades of research in this area, to the best of our knowledge homoleptic quadruple-decker complexes of the f-elements are unknown. This missing link of textbook complexes may be theoretically constructed from four COT-ligands and three lanthanide ions. The corresponding neutral compound would necessarily have to be mixed-valent (vide infra). While examples for mixed-valent d-metal carbon-based sandwich compounds have been known for a long time,\(^{[17]}\) analogue 4f species are hitherto unknown.

Herein, we present the unprecedented synthesis and characterization of the mixed-valent and homoleptic samarium quadruple-decker \([\text{Sm}_{3n/2}(\text{COT})_3]_2\) \((\text{COT})_2=1.4-(\text{Pr}_3\text{Si})_2\text{C}_8\text{H}_6\) by partial reduction of \([\text{Sm}(\text{COT})_2(\text{BH}_4)(\text{thf})]_2\) with KCs.

The synthesis of a neutral COT-based homoleptic lanthanide quadruple-decker requires one divalent and two trivalent lanthanide ions to balance the eightfold negative charge of four COT ligands in the anticipated stacked assembly (Scheme 2, left). We developed some retrosynthetic pathways towards a rational approach and defined a few requirements. These are: i) As center metal a lanthanide is needed, which is sufficiently stable in di- and trivalent oxidation state to allow the synthesis of the necessary building blocks in both oxidation states. As COT ligands are known to act as reducing agents towards Yb\(^{[1]}\) and COT-Eu\(^{[8]}\) species are completely unknown, samarium was chosen based on literature data.\(^{[19]}\) ii) Solubility and steric protection: the bulky disilylated COT\(^{[4]-}\) was employed as ligand. As result, \([\text{Sm}_{3n/2}(\text{COT})_3]_2\) \((\text{COT})_2\) (Scheme 2) was defined as target compound.

Next, three retro-synthetic pathways were defined: A) \([\text{Sm}_{3n/2}(\text{COT})_3]_2\) \((\text{COT})_2\) as reagent for \(\text{Sm}_3\); the elsewhere reported compound \([\text{Sm}_{3n/2}(\text{COT})_3]_2\) \((\text{COT})_2\) as reagent for \(\text{Sm}_3\) and \([\text{Sm}_{3n/2}(\text{COT})_3]_2\) \((\text{COT})_2\) as reagent for \(\text{Sm}_3\) (Scheme 3).

The trivalent building block \([\text{KSm}_{3n/2}(\text{COT})_3]_2\) \((\text{COT})_2\), was obtained from SmI\(_3\) and \([\text{K}_2(\text{COT})_3]_2\) \((\text{COT})_2\) at room temperature in THF (Scheme 3, Figure 1). Compound 2 exhibits a Lewis-base-free polymeric structure in the solid state when crystallized from toluene. The repeating unit is a zigzag-type polymer chain with potassium ions are each bound to one neighboring \(\text{K}[\text{Ln}_{3n/2}(\text{COT})_3]_2\) compounds, which usually only crystallize, when the potassium atom is coordinated by ethereal solvents, crown ethers or cryptands. In this case the formation of monomeric complexes is observed.\(^{[21]}\) One example for a similar polymeric compound is \([\text{Li}(\text{dme})\text{Tb}](\text{COT})_3]_2\), which was reported to crystallize as a Li-bridged polymer from "pentane."\(^{[22]}\) In compound 2 the potassium ions are each bound to one neighboring \(\text{K}[\text{Ln}_{3n/2}(\text{COT})_3]_2\) ligand in a \(\eta^1\)-mode \((\text{K}-\text{C}1-\text{C}2=2.499(6)\text{Å})\) while the opposing ligand is coordinated in a \(\eta^1\)-allyl-type-mode \((\text{K}-\text{C}1-\text{C}6=3.123(2); \text{C}7=2.883(2); \text{C}8=3.170(2))\) in \([\text{KSm}_{3n/2}(\text{COT})_3]_2\). (2). The bent \(\text{K}-\text{COT}_{1,4-\text{SiPr}_3}\) fragment leads to a zigzag-type polymer chain with a bending angle of 149.78(2°) \((\text{C}1-\text{K}-\text{C}12)\) at the potassium positions.

These are not the final page numbers!
Si

Pr3 ligand in the solid state. As expected, the samarium ions are each \( m^8 \cdot h^8 \) coordinated by two COT 1,4-SiPr3 ligands with Sm-Ct (Ct = centroid) distances of 1.9718(4) \( \text{Å} \) (Ct1) and 2.0128(4) \( \text{Å} \) (Ct2) and a Ct1-Sm1-Ct2 bending angle of 171.32(2).\(^8\) The Ct-Sm-Ct angle slightly deviates from the perfectly linear arrangement reported for the unsubstituted complex.\(^{21b}\)

The divalent building block \([(\text{tol})\text{K}(\text{COT} 1,4-\text{SiPr3})-\text{Sm}^\text{II}(\text{COT} 1,4-\text{SiPr3})\text{K}]\), (4), which was synthesized from [SmIII(\text{thf})\_2], and [K(\text{COT} 1,4-\text{SiPr3})]\)\(^{20}\) does not form a polymeric structure in the solid state when crystallized from toluene (Scheme 3). Instead, two \( [\text{Sm}^\text{II}(\text{COT} 1,4-\text{SiPr3})]\)\(^3\) units formally dimerize, whereas the outer potassium ions are capped by toluene molecules (Figure 1). The resulting structure can be considered as Sm/K\(_4\) hexa-decker with an interconnecting slipped dipotassium middle deck. This is to the best of our knowledge an unprecedented structural motif in lanthanide coordination chemistry, which is in stark contrast to reported, unsubstituted COT-based \([(\text{K}(\text{L})\_n)\_2\text{Ln}^\text{II}(\text{COT})\_2]\) \( (\text{L} = \text{thf} \ (n = 3), 18\text{-c}-\text{6} \ (n = 1); \text{Ln} = \text{Eu}, \text{Tm}, \text{Yb}) \) species. Similar to the above-described trivalent compounds, these are commonly isolated as monomeric species where the potassium ions are saturated by Lewis-base-ligands.\(^{23}\) The inner potassium ions are each bound to one COT 1,4-SiPr3 ligand in the expected \( h^8 \)-coordination mode (K1-Ct1 = 2.3000(5) \( \text{Å} \) and connected to the neighboring K2[SmII(COT1,4-SiPr3)]\(^2\) fragment via a \( h^2 \)-bonding mode to a COT 1,4-SiPr3 ligand (K-C6\(_\text{'}\) = 3.045(2) \( \text{Å} \) and K-C7\(_\text{'}\) = 3.168(2) \( \text{Å} \)).

Similar to compound 2, isopropyl groups of the COT 1,4-SiPr3 ligand sterically shield the open potassium atom faces of the inner complex fragment. The \( [\text{Sm}^\text{III}(\text{COT} 1,4-\text{SiPr3})]\)\(^3\) fragments exhibit a twofold \( h^8 \)-coordinated Sm ion with Sm-Ct distances of 2.1876- (3) \( \text{Å} \) (Ct1) and 2.1541- (3) \( \text{Å} \) (Ct2) and a Ct1-Sm1-Ct2 bending angle of 168.98(2).\(^8\)

The Ln-Ct values are in good agreement with the Eu-Ct distance of 2.153 \( \text{Å} \) in \([(\text{K}(\text{thf})\_3)\_2\text{Eu}^\text{II}(\text{COT})\_2]\). In contrast, the strong bending of this fragment is rather surprising compared to literature examples: All reported \([(\text{K}(\text{thf})\_3)\_2\text{Ln}^\text{II}(\text{COT})\_2]\) \( (\text{Ln} = \text{Eu}, \text{Tm}, \text{Yb}) \) compounds exhibit a [\( \text{Ln}^\text{II}(\text{COT})\]\(^2\)- moiety with almost no deviation from linearity.\(^{23b}\) Solely \([(\text{K}(18\text{-c}-\text{6}))\_2\text{Fm}^\text{II}(\text{COT})\_2]\) features a bent central complex unit with a Ct-Tm-Ct angle of 173.9. Consequently, the coordination spheres of the potassium
cations seem to play a significant role for the electrostatic bonding interactions in the lanthanide sandwich fragment. The outer potassium deck is assembled by a \( \eta^8 \)-bound COT\(^{1,4}\)-Si\(_3\)Pr\(_3\) ligand (K2-Ct2 = 2.2832(5) Å) and a disordered \( \eta^9 \)-coordinated toluene moiety (K2-Ct3A/B = 2.9041(5)/2.8874–(5) Å) with a bending angle of Ct2-K-Ct3A/B of 148.90(2)/155.30(2)°. In agreement with the other potassium-COT\(^{1,4}\)-Si\(_3\)Pr\(_3\) assemblies described before, steric shielding by isopropyl groups stabilizes the outer fragments of the hexa-decker type sandwich complex. Aside from investigations towards the application of complex 4 as novel reducing agent in organic and inorganic transformation, the unprecedented hexa-decker motif is of great interest in terms of a possible thulium analogue. Especially, considering recent advances in the synthesis of divalent thulium SMMs. \(^{[23c]}\)

Following the strategies outlined in Scheme 2, [KSm\(^{III}\)(COT\(^{1,4}\)-Si\(_3\)Pr\(_3\))]\(_n\) (2) was reacted with [Sm\(^{II}\)\(_2\)(thf)] (Scheme 2, A and Scheme 4 top) first. Surprisingly, we were not able to isolate the desired product from these attempts. Only intractable product mixtures were obtained even in different solvents and under varying conditions. Also the reaction of [(tol)K(COT\(^{1,4}\)-Si\(_3\)Pr\(_3\))Sm\(^{II}\)(COT\(^{1,4}\)-Si\(_3\)Pr\(_3\))K] (4) with [Sm\(^{III}\)(COT\(^{1,4}\)-Si\(_3\)Pr\(_3\))(BH\(_4\))(thf)] (3) (Scheme 2, B) in different solvents and under varying conditions did not result in the desired product. Instead, only the trivalent compound [KSm\(^{III}\)(COT\(^{1,4}\)-Si\(_3\)Pr\(_3\))]\(_n\) (2) could be isolated as the sole crystalline product (experimental details for all attempts can be found in the SI, page S6). This indicates that ligand rearrangement pathways might be active in addition to the anticipated salt elimination. The fate of the employed divalent Sm\(^{II}\) species could not be clarified. Following the unsuccessful salt elimination approach, we aimed to synthesize the mixed valent quadruple-decker by partial reduction of a trivalent precursor (Scheme 2, C), which might induce ligand rearrangement and formation of the otherwise inaccessible quadruple-decker. Indeed, 3 rapidly reacts with KC\(_8\) at −78 °C as indicated by a quick color change from deep purple to brown. The desired quadruple-decker 1 can be isolated as a yellow-brown crystalline solid in 48 % yield (as single crystals based on the proposed side products listed in Scheme 4) after workup. The molecular structure of 1 in the solid state consists of four COT\(^{1,4}\)-Si\(_3\)Pr\(_3\) ligands and three Sm ions forming the anticipated homoleptic quadruple-decker motif (Figure 2). As result of the partial reduction one of these three Sm ions is in the divalent oxidation state. The resulting eightfold positive charge of all Sm atoms is balanced by the eightfold negative charge of four COT\(^{1,4}\)-Si\(_3\)Pr\(_3\) ligands. An initial analysis of Sm-Ct distances in compound 1 suggests, that the inner samarium ion Sm2 is the divalent one, as the Sm-Ct distances (Sm2-Ct2 = 2.2262(4) Å and Sm2-Ct3 = 2.2157(4) Å) are longer than the corresponding distances for the outer samarium ions Sm1 and Sm3 (Sm1-Ct1 = 1.8803–(4) Å, Sm1-Ct2 = 2.1363(4) Å and Sm3-Ct3 = 2.1594(4) Å, Sm3-Ct4 = 1.8942–(3) Å). The inner Sm-Ct distances are in good agreement with the corresponding Sm-Ct distances in 4 (vide supra), underpinning a III/II/III oxidation state distribution in the sandwich complex.

**Scheme 4.** Transformations based on the Sm\(^{III}\)/ Sm\(^{II}\)/Sm\(^{III}\) system, that are accessible by reduction with KC\(_8\). The denotation “NMR” on reaction arrows indicates that the reaction was performed on an NMR scale and no yields were determined.
Interestingly, the presumably trivalent outer samarium ions Sm1 and Sm3 exhibit a significantly longer distance to the corresponding inner COT1,4-SiPr3 ligands compared to the outer ones. This implies that the bonding situation in compound 1 resembles a dianionic [SmII(COT1,4-SiPr3)]2− fragment that is capped by two [SmIII(COT1,4-SiPr3)3]+ cations. The COT1,4-SiPr3 ligands adapt a staggered conformation with an average torsion angle of 84°. Additionally, the complete sandwich complex is slightly bent with a Sm1-Sm2-Sm3 angle of 156.508(13)° whereas the inner Sm1(COT1,4-SiPr3) unit (Ct2-Sm2-Ct3 = 159.59(2)°) is bent stronger than the outer ones (Ct1-Sm1-Ct2 = 172.75(2)° and Ct3-Sm3-Ct4 = 168.49(2)°). The bent metallocene structure of the presumably divalent fragment is even more pronounced than in complex 4 and to the best of our knowledge unprecedented for divalent Ln-COT complexes. A possible explanation is the presence of eight bulky Pr3Si groups in the quadruple-decker, inducing a comparatively strong bending of the central fragment to relief steric pressure from the system.

To support the structure-implied calculations a mixed valent quadruple-decker complex with a III/III oxidation state distribution, quantum chemical calculations23 at DFT level (PBE025/def2-SV(P)26) were performed for 1. With the Fermi-smearing approach27 applied to the calculations of the experimental structure, a high-spin state with altogether 16 unpaired electrons was found. For this state, the valence s/p/d/f contributions from the Sm atoms to total and spin density were calculated with the natural population analysis28 and compared to that of the typical SmII and SmIII compounds SmIIIX2 and SmIIIX3, (X = Cl, Br, I). The results are shown in Table 1. Concerning the total density, the most striking differences of SmIIIX3 compared to SmIIIX2 are found in the contributions of the f- and the d-orbitals. For SmIII, f/d valence orbital contributions amount to ca. 5.26/0.80 electrons, for SmII to 6.01/0.26 electrons. The f/d contributions of Sm1, 5.40/0.87 and Sm3, 5.41/0.84 electrons, are very close to that of SmIII, while that of Sm2, 5.99/0.33 electrons, are very close to that of SmIIIX3. s and p contributions are small and similar for all situations and compounds. For the spin density, the f-orbital contributions again show the corresponding agreements within 0.1 electrons, and the other contributions are below 0.1 electrons. Thus, the assignment of oxidation states +3 for the outer atoms Sm1 and Sm3 and +2 for the inner Sm2 is very well supported by the calculations. Also, interpreting 1 as dianionic [SmII(COT1,4-SiPr3)]2− capped by two [SmIII(COT1,4-SiPr3)3]+ cations (vide supra) is in line with the calculated partial charges for the three parts, amounting to −1.22 and twice +0.61. We finally note that the magnetic coupling between the Sm atoms is small. The difference of the high-spin state to the broken-symmetry state (with a surplus of six beta electrons for Sm2) amounts to less than 0.5 J/mol−1; moreover, the s/p/d/f contributions of the Sm atoms for this state are virtually identical to that for the high-spin state, see Table S5.

To gain some insight into the formation mechanism of the quadruple-decker 1 NMR experiments were performed. Especially the origin of the fourth COT1,4-SiPr3 ligand is in question at this point. The stoichiometry of the reaction can either be balanced by the formation of [Sm(BH4)2(thf)]3 or elemental SmI, both of which explain the presence of four ligands per three Sm ions. The existence of [Sm(BH4)2(thf)], in the reaction mixture can easily be precluded, as no signs of this species could be found in the bulk reaction mixture or in NMR experiments. Additionally, it could be shown that [Sm(BH4)2(thf)], is not stable under the here applied reducing conditions. NMR-scale reactions of [Sm(BH4)2(thf)] with KC8 in [D8]THF result in silent ‘H- and 11B-NMR spectra, accompanied by the formation of a dark grey solid, presumably elemental samarium.29 Likewise, the simultaneous formation of SmII and [K2(COT1,4-SiPr3)] by reduction of the starting material 3 seems feasible. To further prove the presence of [K2(COT1,4-SiPr3)], NMR experiments with varying KC8 ratios were performed (Scheme 4). Reaction of 3 and KC8 in a 4:1 ratio in d8-THF yields a 2:1 mixture of complexes 2 and 3 (Figure S12). Compound 2 could be produced by salt elimination between 3 and in situ formed [K2(COT1,4-SiPr3)]2. Residual starting material 3 can be explained by insufficient amounts of KC8 for full conversion. If 3 and KC8 are conversely reacted in a 1:4 ratio in d8-THF, clean and quantitative conversion to the divalent compound 4 was observed. In concordance with the 4:1 reaction this can again be explained by formation of [K2(COT1,4-SiPr3)] which quickly reacts to 2. The trivalent species 2 is subsequently reduced by excess KC8 to give compound 4 (Scheme 4). A similar reactivity was recently described for the reduction of trivalent [K(thf)3Tm(COT)]2.25d. Likewise, isolated 2 can be reduced by KC8 to give 4 in an NMR scale reaction. Finally, the 1:1 reaction of 3 and KC8 yields the quadruple-decker 1, as already described above. Consequently, 1, 2, and 4 can be formed by reducing 3 with KC8 depending on the exact stoichiometric ratio of the precursors. This rather surprising diversity of possible transformations in this simple system is depicted in Scheme 4. Moreover, it is feasible that the formation of the quadruple-decker 1 is initiated by complete reduction of parts of the employed starting material 3 to give SmII and

| Valence population | SmIIIX2 | Sm1 in 1 | Sm3 in 1 | SmIIIX3 | Sm2 in 1 |
|--------------------|---------|---------|---------|---------|---------|
| s+ + s+ | 0.198 | 0.074 | 0.073 | 0.099 | 0.054 |
| p+ + p+ | 0.038 | 0.000 | 0.000 | 0.047 | 0.007 |
| d+ + d+ | 0.800 | 0.870 | 0.836 | 0.262 | 0.334 |

Our findings highlight that the structural diversity of 4f-element metalloccenes is still far from being exhausted. During our attempts to rationally synthesize a homoleptic samarium quadruple-decker, two building blocks with unique structural properties could be isolated. These are likely induced by the peripheral substitution pattern of the employed COT1,4-Si ligands. Especially the eye-catching molecular solid-state structure of compound \( \text{K}_2(\text{COT}^{1,4-\text{Si}^3}) \) with its mixed-metallic hexa-decker type sandwich assembly demonstrates that ligand substitution can greatly influence the structure of lanthanide-COT metalloccenes. Moreover, we could show that the reduction of the half-sandwich complex \( \text{COT} \) yields the archetypal homoleptic quadruple-decker \( 1 \). This metalloccene is the first homoleptic quadruple-decker of the f-elements and due to the inherent need of charge balance the only classical mixed valent sandwich assembly of the lanthanides reported to date. Additionally, NMR experiments to probe the influence of the stoichiometric ratio \( 3/\text{KC} \) on the formation of \( 1 \) unveiled a surprising variety of reductive transformations that are accessible starting from compound \( 3 \). Therefore, we hope that our findings will, aside from their importance in basic research and structural chemistry, stimulate further investigations in this area based on uncommon reaction pathways in this highly flexible and versatile system.

These are not the final page numbers!
The synthesis of the first well-defined neutral and homoleptic (same metal, same ligand) all-carbon-based quadruple-decker complexes $[\text{Sm}^{III/II/III}\{(\text{COT}^{1,4-iPr})_3\}]$ along with other unique sandwich complexes is shown.
