Abstract
This paper is a sequel to [19] and continues the study of quantum logic via dagger kernel categories. It develops the relation between these categories and both orthomodular lattices and Foulis semigroups. The relation between the latter two notions has been uncovered in the 1960s. The current categorical perspective gives a broader context and reconstructs this relationship between orthomodular lattices and Foulis semigroups as special instance.

1 Introduction
Dagger kernel categories have been introduced in [19] as a relatively simple setting in which to study categorical quantum logic. These categories turn out to have orthomodular logic built in, via their posets KSub(X) of kernel subobjects that can be used to interpret predicates on X. The present paper continues the study of dagger kernel categories, especially in relation to orthomodular lattices and Foulis semigroups. The latter two notions have been studied extensively in the context of quantum logic. The main results of this paper are as follows.

(1) A special category \textbf{OMLatGal} is defined with orthomodular lattices as objects and Galois connections between them as morphisms; it is shown that:

- \textbf{OMLatGal} is itself a dagger kernel category—with some additional structure such a dagger biproducts, and an opclassifier;

- for each dagger kernel category \textbf{D} there is a functor \textbf{D} \rightarrow \textbf{OMLatGal} preserving the dagger kernel structure; hence \textbf{OMLatGal} contains in a sense all dagger kernel categories.
For each object \(X\) in a dagger kernel category, the homset \(\text{Endo}(X) = D(X,X)\) of endo-maps is a Foulis semigroup.

Every Foulis semigroup \(S\) yields a dagger kernel category \(\mathcal{K}^\dagger(S)\) via the “dagger Karoubi” construction \(\mathcal{K}^\dagger(\cdot)\).

Translations between orthomodular lattices and Foulis semigroups have been described in the 1960s, see e.g. [12, 13, 14, 4, 26]. These translations appear as special instances of the above results:

- given a Foulis semigroup \(S\), all the kernel posets \(\text{KSub}(s)\) are orthomodular lattices, for each object \(s \in \mathcal{K}^\dagger(S)\) of the associated dagger kernel category (using point (3) mentioned above). For the unit element \(s = 1\) this yields the “old” translation from Foulis semigroups to orthomodular lattices;

- given an orthomodular lattice \(X\), the set of (Galois) endomaps \(\text{Endo}(X) = \text{OMLatGal}(X,X)\) on \(X\) in the dagger kernel category \(\text{OMLatGal}\) forms a Foulis semigroup—using points (1) and (2). Again this is the “old” translation, from orthomodular lattices to Foulis semigroups.

Since dagger kernel categories are essential in these constructions we see (further) evidence of the relevance of categories in general, and of dagger kernel categories in particular, in the setting of quantum (logical) structures.

The paper is organised as follows. Section 2 first recalls the essentials about dagger kernel categories from [19] and also about the (dagger) Karoubi envelope. It shows that dagger kernel categories are closed under this construction. Section 3 introduces the fundamental category \(\text{OMLatGal}\) of orthomodular lattices with Galois connections between them, investigates some of its properties, and introduces the functor \(\text{KSub}: D \to \text{OMLatGal}\) for any dagger kernel category \(D\). Subsequently, Section 4 recalls the definition of Foulis semigroups, shows how they arise as endo-homsets in dagger kernel categories, and proves that their dagger Karoubi envelope yields a dagger kernel category. The paper ends with some final remarks and further questions in Section 5.

## 2 Dagger kernel categories

Since the notion of dagger kernel category is fundamental in this paper we recall the essentials from [19], where this type of category is introduced. Further details can be found there.

A dagger kernel category consists of a category \(D\) with a dagger functor \(\dagger: D^{\text{op}} \to D\), a zero object \(0 \in D\), and dagger kernels. The functor \(\dagger\) is the identity on objects \(X \in D\) and satisfies \(f^\dagger \dagger = f\) on morphisms \(f\). The zero object \(0\) yields a zero map, also written as \(0\), namely \(X \to 0 \to Y\) between any two objects \(X, Y \in D\). A dagger kernel of a map \(f: X \to Y\) is a kernel map, written as \(k: K \dagger \to X\), which is—or can be chosen as—a dagger mono, meaning that \(k^\dagger \circ k = \text{id}_K\). Often we write \(k = \ker(f)\), and \(\text{coker}(f) = \ker(f^\dagger)^\dagger\).
for the cokernel of $f$. The definition $k^\perp = \ker(k^\dagger)$ for a kernel $k$ yields an orthocomplement.

We write $\text{DKC}$ for the category with dagger kernel categories as objects and functors preserving $\dagger, 0, \ker$.

The main examples of dagger kernel categories are: $\text{Rel}$, the category of sets and relations, its subcategory $\text{pInj}$ of sets and partial injections, $\text{Hilb}$, the category of Hilbert spaces and bounded/continuous linear maps between them, and $\text{PHilb}$, the category of projective Hilbert spaces. This paper adds another example, namely $\text{OLatGal}$.

The main results from [19] about dagger kernel categories are as follows.

1. Each poset $\text{KSub}(X)$ of kernel subobjects of an object $X$ is an orthomodular lattice; this is the basis of the relevance of dagger kernel categories to quantum logic.

2. Pullbacks of kernels exist along arbitrary maps $f: X \to Y$, yielding a pullback (or substitution) functor $f^{-1}: \text{KSub}(Y) \to \text{KSub}(X)$. Explicitly, like in [15], $f^{-1}(n) = \ker(\text{coker}(n) \circ f)$.

3. This pullback functor $f^{-1}$ has a left adjoint $\exists_f: \text{KSub}(X) \to \text{KSub}(Y)$, corresponding to image factorisation. These $f^{-1}$ and $\exists_f$ only preserve part of the logical structure—meets are preserved by $f^{-1}$ and joins by $\exists_f$, via the adjointness—but for instance negations and joins are not preserved by substitution $f^{-1}$, unlike what is standard in categorical logic, see e.g. [25]. Substitution $f^{-1}$ and existential quantification $\exists_f$ are inter-expressible, via $f^{-1}(m)^\perp = \exists_f(m^\perp)$.

4. The logical “Sasaki” hook $\supset$ and “and-then” $\&$ connectives—together with the standard adjunction between them [11, 7]—arise via this adjunction $\exists_f \dashv f^{-1}$, namely for $m, n, k \in \text{KSub}(X)$ as:

\[
m \supset n = \mathcal{E}(m)^{-1}(n) \quad k \& m = \exists_{\mathcal{E}(m)}(k) = m^\perp \vee (m \wedge n) = m \wedge (m^\perp \vee k),
\]

where $\mathcal{E}(m) = m \circ m^\dagger: X \to X$ is the effect (see [10]) associated with the kernel $m$.

2.1 Karoubi envelope

Next we recall the essentials of the so-called Karoubi envelope (see [27] or [15, Chapter 2, Exercise B]) construction—and its “dagger” version—involving the free addition of splittings of idempotents to a category. The construction will be used in Section 3 to construct a dagger kernel category out of a Foulis semigroup. It is thus instrumental, and not studied in its own right.

An idempotent in a category is an endomap $s: X \to X$ satisfying $s \circ s = s$. A splitting of such an idempotent $s$ is a pair of maps $e: X \to Y$ and $m: Y \to X$
with \( m \circ e = s \) and \( e \circ m = \text{id}_Y \). Clearly, \( m \) is then a mono and \( e \) is an epi. Such a splitting, if it exists, is unique up-to-isomorphism.

For an arbitrary category \( C \) the so-called Karoubi envelope \( K(C) \) has idempotents \( s: X \to X \) in \( C \) as objects. A morphism \( (X \xrightarrow{s} X) \to (Y \xrightarrow{t} Y) \) in \( K(C) \) consists of a map \( f: X \to Y \) in \( C \) with \( f \circ s = f = t \circ f \). The identity on an object \( (X,s) \in K(C) \) is the map \( s \) itself. Composition in \( K(C) \) is as in \( C \). The mapping \( X \mapsto (X, \text{id}_X) \) thus yields a full and faithful functor \( \mathcal{I}: C \to K(C) \).

The Karoubi envelope \( K(C) \) can be understood as the free completion of \( C \) with splittings of idempotents. Indeed, an idempotent \( f: (X,s) \to (X,s) \) in \( K(C) \) can be split as \( f = ((X,s) \xrightarrow{s} (X,f)) \). If \( F: C \to D \) is a functor to a category \( D \) in which endomorphisms split, then there is an up-to-isomorphism unique functor \( F: K(C) \to D \) with \( F \circ \mathcal{I} \cong F \).

Hayashi [17] (see also [22]) has developed a theory of semi-functors and semi-adjunctions that can be used to capture non-extensional features, without uniqueness of mediating maps, like for of exponents \( \Rightarrow [31, 28] \). The Karoubi envelope can be used to turn such “semi” notions into proper (extensional) ones. This also happens in Section 4.

Now assume \( D \) is a dagger category. An endomap \( s: X \to X \) in \( D \) is called a self-adjoint idempotent if \( s^\dagger = s = s \circ s \). A splitting of such an \( s \) consists, as before, of maps \( m, e \) with \( m \circ e = s \) and \( e \circ m = \text{id} \). In that case \( e^\dagger, m^\dagger \) is also a splitting of \( s \), so that we get an isomorphism \( \varphi = m^\dagger \circ m \) in a commuting diagram:

![Diagram](image)

Hence \( e^\dagger = m \), as subobjects, and \( m^\dagger = e \) as quotients.

The dagger Karoubi envelope \( K^\dagger(D) \) of \( D \) is the full subcategory of \( K(D) \) with self-adjoint idempotents as objects, see also [33]. This is again a dagger category, since if \( f: (X,s) \to (Y,t) \) in \( K^\dagger(D) \), then \( f^\dagger: (Y,t) \to (X,s) \) because:

\[
s \circ f^\dagger = s^\dagger \circ f^\dagger = (f \circ s)^\dagger = f^\dagger.
\]

Similarly \( f^\dagger \circ t = f^\dagger \). The functor \( \mathcal{I}: D \to K(D) \) factors via \( K^\dagger(D) \to K(D) \). One can understand \( K^\dagger(D) \) as the free completion of \( D \) with splittings of self-adjoint idempotents.

Selinger [33] shows that the dagger Karoubi envelope construction \( K^\dagger(-) \) preserves dagger biproducts and dagger compact closedness. Here we extend this with dagger kernels in the next result. It will not be used in the sequel but is included to show that the dagger Karoubi envelope is quite natural in the current setting.

**Proposition 1** If \( D \) is a dagger kernel category, then so is \( K^\dagger(D) \). Moreover, the embedding \( \mathcal{I}: D \to K^\dagger(D) \) is a map of dagger kernel categories.
Proof For each object \( X \in D \), the zero map \( 0: X \to X \) is a zero object in \( D \), since there is precisely one map \( (X, 0) \to (Y, t) \) in \( K^\dagger(D) \), namely the zero map \( 0: X \to Y \). As canonical choice we take the zero object \( 0 \in D \) with zero map \( 0 = \text{id}_0: 0 \to 0 \), which is in the range of \( \mathcal{T}: D \to K^\dagger(D) \).

For an arbitrary map \( f: (X, s) \to (Y, t) \) in \( K^\dagger(D) \), let \( k: K \to X \) be the kernel of \( f: X \to Y \) in \( D \). We obtain a map \( s': K \to K \), as in:

\[
\begin{array}{cc}
K & X \\
\downarrow^k & \downarrow^f \\
K & X
\end{array}
\]
since \( f \circ s \circ k = f \circ k = 0 \). We obtain that \( s' \) is a self-adjoint idempotent, using that \( k \) is a dagger mono (i.e. satisfies \( k^\dagger \circ k = \text{id} \)).

\[
s' \circ s = k^\dagger \circ k \circ s', \quad s'^\dagger = s'^\dagger \circ k^\dagger \circ k \\
= k^\dagger \circ s \circ k \circ s', \quad = (k \circ s')^\dagger \circ k \\
= k^\dagger \circ s \circ s \circ k, \quad \quad = (s \circ k)^\dagger \circ k \\
= k^\dagger \circ s \circ k, \quad \quad = k^\dagger \circ s^\dagger \circ k \\
= k^\dagger \circ k \circ s', \quad \quad = k^\dagger \circ s \circ k \\
= s'. \quad \quad \quad \quad \quad \quad \quad = s'.
\]

This yields a dagger kernel in \( K^\dagger(D) \),

\[
(K, s') \xrightarrow{s \circ k} (X, s) \xrightarrow{f} (Y, t)
\]
since:

\( \bullet \) \( s \circ k \) is a morphism in \( K^\dagger(D) \): \( s \circ (s \circ k) = s \circ k \) and \( (s \circ k) \circ s' = s \circ s \circ k = s \circ k \);

\( \bullet \) \( s \circ k \) is a dagger mono:

\[
(s \circ k)^\dagger \circ (s \circ k) = (k \circ s')^\dagger \circ (k \circ s') \\
= s'^\dagger \circ k^\dagger \circ k \circ s' \\
= s' \circ s' \\
= s' \\
= \text{id}_{(K, s')};
\]

\( \bullet \) \( f \circ (s \circ k) = f \circ k = 0 \);

\( \bullet \) if \( g: (Z, r) \to (X, s) \) satisfies \( f \circ g = 0 \), then there is a map \( h: Z \to K \) in \( D \) with \( k \circ h = g \). Then \( s' \circ h = h \), since \( k \circ s' \circ h = s \circ k \circ h = s \circ g = g = k \circ h \). Similarly, \( h \circ r = h \), since \( k \circ h \circ r = g \circ r = g = k \circ h \). Hence \( h \) is a morphism \( (Z, r) \to (K, s') \) in \( K^\dagger(D) \) with \( (s \circ k) \circ h = s \circ g = g \).

It is the unique one with this property since \( s \circ k \) is a (dagger) mono. \( \square \)
Example 2 In the category \(\text{Hilb}\) self-adjoint idempotents \(s: H \rightarrow H\) are also called projections. They can be written as \(s = m \circ m^\dagger = \mathcal{E}(m)\) for a closed subspace \(m: M \rightarrow H\), see any textbook on Hilbert spaces (e.g. [9]). Hence they split already in \(\text{Hilb}\), and so the dagger Karoubi envelope \(\mathcal{K}^\dagger(\text{Hilb})\) is isomorphic to \(\text{Hilb}\): it does not add anything.

For the category \(\text{Rel}\) of sets and relations the situation is different. A self-adjoint idempotent \(S: X \rightarrow X\) is a relation \(S \subseteq X \times X\) that is both symmetric (since \(S^\dagger = S\)) and transitive (since \(S \circ S = S\)), and thus a “partial equivalence relation”, commonly abbreviated as PER. The dagger Karoubi envelope \(\mathcal{K}^\dagger(\text{Rel})\) has such PERs as objects. A morphism \(R: (S \subseteq X \times X) \rightarrow (T \subseteq Y \times Y)\) is a relation \(R: X \rightarrow Y\) with \(R \circ S = R = T \circ R\).

Finally we note that the “effect” operation \(\mathcal{E}(m) = m \circ m^\dagger\) can be described as a functor from the (total) category \(\text{KSub}(D)\) of kernels of a dagger kernel category (see [19]) to the dagger Karoubi envelope \(\mathcal{K}^\dagger(D)\) as in the diagram:

\[
\text{KSub}(D) \xrightarrow{\mathcal{E}(-)} \mathcal{K}^\dagger(D)
\]

via:

\[
M \xrightarrow{\mathcal{E}} N \\
\downarrow m \\
X \xrightarrow{f} Y
\]

\[
\rightarrow (X \xrightarrow{\mathcal{E}(m)} X) \xrightarrow{f \circ \mathcal{E}(m)} (Y \xrightarrow{\mathcal{E}(n)} Y)
\]

We use that the necessarily unique map \(\varphi: M \rightarrow N\) with \(n \circ \varphi = f \circ m\) satisfies \(\varphi = n^\dagger \circ n \circ \varphi = n^\dagger \circ f \circ m\). Hence:

\[
\mathcal{E}(n) \circ f \circ \mathcal{E}(m) = n \circ n^\dagger \circ f \circ m \circ m^\dagger = n \circ \varphi \circ m^\dagger = f \circ m \circ m^\dagger = f \circ \mathcal{E}(m),
\]

so that \(f \circ \mathcal{E}(m)\) is a morphism \(\mathcal{E}(m) \rightarrow \mathcal{E}(n)\) in the dagger Karoubi envelope \(\mathcal{K}^\dagger(D)\). It is not hard to see that this functor is full.

3 Ortomodular lattices and Dagger kernel categories

In [19] it was shown how each dagger kernel category gives rise to an indexed collection of ortomodular lattices, given by the posets of the kernel subobjects \(\text{KSub}(X)\) of each object \(X\). Here we shall give a more systematic description of the situation and see that a suitable category \(\text{OMLatGal}\) of ortomodular lattices—with Galois connections between them—is itself a dagger kernel category. The mapping \(\text{KSub}(\cdot)\) turns out to be functor to this category \(\text{OMLatGal}\), providing a form of representation of dagger kernel categories.

We start by recalling the basic notion of ortomodular lattices. They may be understood as a non-distributive generalisation of Boolean algebras. The ortomodularity formulation is due to [23], following [3].
Definition 3 A meet semi-lattice \((X, \wedge 1)\) is called an ortholattice if it comes equipped with a function \((-)^{\perp}: X \to X\) satisfying:

- \(x^{\perp \perp} = x\);
- \(x \leq y\) implies \(y^{\perp} \leq x^{\perp}\);
- \(x \wedge x^{\perp} = 0\).

One can then define a bottom element as \(0 = 1 \wedge 1^{\perp} = 1^{\perp}\) and join by \(x \vee y = (x^{\perp} \wedge y^{\perp})^{\perp}\), satisfying \(x \vee x^{\perp} = 1\).

Such an ortholattice is called orthomodular if it satisfies (one of) the three equivalent conditions:

- \(x \leq y\) implies \(y = x \vee (x^{\perp} \wedge y)\);
- \(x \leq y\) implies \(x = y \wedge (y^{\perp} \vee x)\);
- \(x \leq y\) and \(x^{\perp} \wedge y = 0\) implies \(x = y\).

We shall consider two ways of organising orthomodular lattices into a category.

Definition 4 The categories \(\text{OMLat}\) and \(\text{OMLatGal}\) both have orthomodular lattices as objects.

1. A morphism \(f: X \to Y\) in \(\text{OMLat}\) is a function \(f: X \to Y\) between the underlying sets that preserves \(\wedge, 1, (-)^{\perp}\) — and thus also \(\leq, \vee\) and \(0\):

2. A morphism \(X \to Y\) in \(\text{OMLatGal}\) is a pair \(f = (f_*, f^*)\) of “antitone” functions \(f_*: X^{\text{op}} \to Y\) and \(f^*: Y \to X^{\text{op}}\) forming a Galois connection (or adjunction \(f^* \dashv f_*\)): \(x \leq f^*(y)\) iff \(y \leq f_*(x)\) for \(x \in X\) and \(y \in Y\).

The identity morphism on \(X\) is the pair \((\perp, \perp)\) given by the self-adjoint map \(\text{id}^* = \text{id}_* = (-)^{\perp}: X^{\text{op}} \to X\). Composition of \(X \xrightarrow{f} Y \xleftarrow{g} Z\) is given by:

\[
(g \circ f)_* = g_* \circ \perp \circ f_* \quad \text{and} \quad (g \circ f)^* = f^* \circ \perp \circ g^*.
\]

The category \(\text{OMLat}\) is the more obvious one, capturing the (universal) algebraic notion of morphism as structure preserving mapping. However, the category \(\text{OMLatGal}\) has more interesting structure, as we shall see. It arises by restriction from a familiar construction to obtain a (large) dagger category with involutive categories as objects and adjunctions between them, see [18].

The components \(f_*: X^{\text{op}} \to Y\) and \(f^*: Y \to X^{\text{op}}\) of a map \(f: X \to Y\) in \(\text{OMLatGal}\) are not required to preserve any structure, but the Galois connection yields that \(f_*\) preserves meets, as right adjoint, and thus sends joins in \(X\) (meets in \(X^{\text{op}}\)) to meets in \(Y\), and dually, \(f^*\) preserves joins and sends joins in \(Y\) to meets in \(X\).
The category \(\text{OMLatGal}\) indeed has a dagger, namely by twisting:

\[
(f_\ast, f^\ast)^\dagger = (f^\ast, f_\ast).
\]

A morphism \(f: X \to Y\) in \(\text{OMLatGal}\) is a dagger mono precisely when it satisfies \(f^\ast(f_\ast(x)^\perp) = x^\perp\) for all \(x \in X\), because \(\text{id}^\ast(x) = x^\perp = \text{id}_x(x)\) and:

\[
(f^\dagger \circ f)^\ast(x) = f^\ast(f_\ast(x)^\perp) = (f^\dagger \circ f)_\ast(x).
\]

In a Galois connection like \(f^\ast \dashv f_\ast\) one map determines the other. This standard result can be useful in proving equalities, which, for convenience, we make explicit.

**Lemma 5** Suppose we have parallel maps \(f, g: X \to Y\) in \(\text{OMLatGal}\). In order to prove \(f = g\) it suffices to prove either \(f_\ast = g_\ast\) or \(f^\ast = g^\ast\).

**Proof** We shall prove that \(f_\ast = g_\ast\) suffices to obtain also \(f^\ast = g^\ast\). For all \(x \in X\) and \(y \in Y\),

\[
x \leq f^\ast(y) \iff y \leq f_\ast(x) \iff x \leq g^\ast(y).
\]

Given \(y\) this holds for all \(x\), and so in particular for \(x = f^\ast(y)\) and \(x = g^\ast(y)\), which yields \(f^\ast(y) = g^\ast(y)\). \(\square\)

Despite this result we sometimes explicitly write out both equations \(f_\ast = g_\ast\) and \(f^\ast = g^\ast\), in particular when there is a special argument involved.

The following elementary lemma is fundamental.

**Lemma 6** Let \(X\) be an orthomodular lattice, with element \(a \in X\).

1. The (principal) downset \(\downarrow a = \{u \in X \mid u \leq a\}\) is again an orthomodular lattice, with order, conjunctions and disjunctions as in \(X\), but with its own orthocomplement \(\perp_a\) given by \(u^{\perp_a} = a \wedge u^\perp\), where \(\perp\) is the orthocomplement from \(X\).

2. There is a dagger mono \(\downarrow a \to X\) in \(\text{OMLatGal}\), for which we also write \(a_\ast\), with

\[
a_\ast(u) = u^\perp \quad \text{and} \quad a^\ast(x) = a \wedge x^\perp.
\]

**Proof** For the first point we check, for \(u \in \downarrow a\),

\[
u^{\perp_{a^\perp}} = a \wedge (a \wedge u^\perp)^\perp = a \wedge (a^\perp \vee u) = u,
\]

by orthomodularity, since \(u \leq a\). We get a map in \(\text{OMLatGal}\) because for arbitrary \(u \in \downarrow a\) and \(x \in X\),

\[
x \leq a_\ast(u) = u^\perp \iff u \leq x^\perp \iff u \leq a \wedge x^\perp = a^\ast(x).
\]

This map \(a: \downarrow a \to X\) is a dagger mono since:

\[
a^\ast(a_\ast(u)^\perp) = a^\ast(u^\perp^\perp) = a^\ast(u) = a \wedge u^\perp = u^{\perp_{a^\perp}}. \quad \square
\]
We should emphasise that the equation \( u^{\perp_1 a \perp_1} = u \) only holds for \( u \leq a \), and not for arbitrary elements \( u \).

Later, in Proposition \([11]\) we shall see that these maps \( |a| \mapsto X \) are precisely the kernels in the category \( \text{OMLatGal} \). But we first show that this category has kernels in the first place.

To begin, \( \text{OMLatGal} \) has a zero object \( 0 \), namely the one-element orthomodular lattice \( \{*\} \). We can write its unique element as \( * = 0 = 1 \). Let us show that the lattice \( 0 \) is indeed a final object in \( \text{OMLatGal} \). Let \( X \) be an arbitrary orthomodular lattice. The only function \( f_*: X \to 0 \) is \( f_*(x) = 1 \). It has an obvious left adjoint \( f^*: 0 \to L \) defined by \( f^*(1) = 1 \):

\[
\begin{align*}
x \leq f^*(1) &= 1 \\
1 &\leq f_*(x)
\end{align*}
\]

Likewise, the unique morphism \( g: 0 \to Y \) is given by \( g_*(1) = 1 \) and \( g^*(y) = 1 \). Hence the zero morphism \( z: X \to Y \) is determined by \( z_*(x) = 1 \) and \( z^*(y) = 1 \).

**Theorem 7** The category \( \text{OMLatGal} \) is a dagger kernel category. The (dagger) kernel of a morphism \( f: X \to Y \) is \( \downarrow k \to X \), where \( k = f^*(1) \in X \), like in Lemma \([6]\).

**Proof** The composition \( f \circ k \) is the zero map \( \downarrow k \to Y \). First, for \( u \in \downarrow f^*(1) \),

\[
(f \circ k)_*(u) = f_*(k_*(u)^\perp) = f_*(u) = 1,
\]

because \( u \leq f^*(1) \) in \( X \) and so \( 1 \leq f_*(u) \) in \( Y \). And for \( y \in Y \),

\[
(f \circ k)^*(y) = k^*(f^*(y)^\perp) = f^*(y)^\perp = f^*(y \lor 1) = f^*(1) = k = 1_{\downarrow k},
\]

because \( f^*: Y \to X^{\text{op}} \) preserves joins as a left adjoint.

Now suppose that \( g \circ k \) equals the zero morphism, for \( g: Z \to X \). Then \( f_* \circ \perp \circ g_* = 1 \) and \( g^* \circ \perp \circ f^* = 1 \). Hence for \( z \in Z \) we have \( 1 \leq f_*(g_*(z)^\perp) \), so \( g_*(z)^\perp \leq f^*(1) = k \). Define \( h_*: Z^{\text{op}} \to \downarrow k \) by \( h_*(z) = g_*(z) \land k \), and define \( h^*: \downarrow k \to Z^{\text{op}} \) by \( h^*(u) = g^*(u) \). Then \( h^* \perp h_* \) since for \( u \leq k \) and \( z \in Z \):

\[
\begin{align*}
z &\leq g^*(u) = h^*(u) \\
u &\leq g_*(z) \\
u &\leq g_*(z) \land k = h_*(z)
\end{align*}
\]

whence \( h \) is a well-defined morphism of \( \text{OMLatGal} \). It satisfies:

\[
(k \circ h)_*(z) = k_*(h_*(z)^{\perp_{1 \perp_1}})
\]

\[
= k_*(g_*(z) \land k)^{\perp_{1 \perp_1}}
\]

\[
= ((g_*(z) \land k)^{\perp_{1 \perp_1}} \land k)^{\perp_{1 \perp_1}}
\]

\[
= (g_*(z) \land k)^{\perp_{1 \perp_1}} \land k \land k
\]

\[
= (g_*(z) \land k) \lor k
\]

\[
= g_*(z),
\]
by orthomodularity since $k^\perp = f^*(1)^{\perp} \leq g_*(z)$ because $g_*(z)^{\perp} \leq f^*(1) = k$
which follows from $1 \leq f_*(g_*(z)^{\perp})$. Hence $h$ is a mediating morphism satisfying $k \circ h = g$. It is the unique such morphism, since $k$ is a (dagger) mono. □

For convenience we explicitly describe some of the basic structure that results
from dagger kernels, see [19], namely cokernels and factorisations, given by
dagger kernels and zero-epis. We start with cokernels and zero-epis.

**Lemma 8** The cokernel of a map $f: X \rightarrow Y$ in OMLatGal is:

$$\text{coker}(f) = \left( \begin{array}{c} Y \downarrow \rightarrow \downarrow \downarrow f_*(1) \end{array} \right)$$

with \[
\begin{aligned}
c_*(y) &= y^{\perp} \land f_*(1) \\
c^*(v) &= v^{\perp}
\end{aligned}
\]

Then:

$$f \text{ is zero-epi } \iff \text{coker}(f) = 0 \iff f_*(1) = 0.$$

**Proof** Since:

$$\text{coker}(f) = \ker(f^\dagger) = \left( \begin{array}{c} (f^\dagger)^*(1) \downarrow \rightarrow Y \end{array} \right)^\dagger = \left( \begin{array}{c} Y \downarrow \rightarrow \downarrow \downarrow f_*(1) \end{array} \right).$$

We recall from [19] that each map $f$ in a dagger kernel category has a zero-epi/kernel factorisation $f = i_f \circ e_f$. In combination with the factorisation of $f^\dagger$ it yields a factorisation $f = i_f \circ m_f \circ (i_f)^\dagger$ as in:

\[
\begin{array}{c}
X & \xrightarrow{(i_f)^\dagger} & \text{Im}(f^\dagger) & \xrightarrow{m_f} & \text{Im}(f) & \xrightarrow{i_f} & Y \\
\downarrow \downarrow \downarrow f^\dagger & & & \downarrow m_f & \downarrow f^\dagger & & \downarrow i_f
\end{array}
\]

where the map $m_f$ is both zero-epic and zero-monic, and where $m_f \circ (i_f)^\dagger = e_f$, the zero-epic part of $f$.

**Lemma 9** For a map $f: X \rightarrow Y$ in OMLatGal one has:

\[
\left( \begin{array}{c} \text{Im}(f) = \downarrow f_*(1)^{\perp} \xrightarrow{i_f} Y \end{array} \right) \] \text{ with } \[
\begin{aligned}
(i_f)_*(v) &= v^{\perp} \\
(i_f)^*(y) &= y^{\perp} \land f_*(1)^{\perp}
\end{aligned}
\]

is \[
\left( \begin{array}{c} X \xrightarrow{e_f} \downarrow f_*(1)^{\perp} \end{array} \right)
\]

\[
\left( \begin{array}{c} \text{Im}(f^\dagger) \xrightarrow{m_f} \downarrow f_*(1)^{\perp} \end{array} \right) \] \text{ is } \[
\begin{aligned}
(e_f)_*(x) &= f_*(x) \land f_*(1)^{\perp} \\
(e_f)^*(v) &= f^*(v)
\end{aligned}
\]

\[
\left( \begin{array}{c} Y \xrightarrow{(i_f)^\dagger} \text{Im}(f^\dagger) \xrightarrow{i_f} \text{Im}(f) \end{array} \right)
\]

is \[
\left( \begin{array}{c} \text{Im}(f^\dagger) \xrightarrow{m_f} \downarrow f_*(1)^{\perp} \end{array} \right) \] \text{ is } \[
\begin{aligned}
(m_f)_*(x) &= f_*(x) \land f_*(1)^{\perp} \\
(m_f)^*(v) &= f^*(v) \land f^*(1)^{\perp}
\end{aligned}
\]
Proof This is just a matter of unravelling definitions. For instance,
\[ \text{Im}(f) = \ker(\text{coker}(f)) = \ker \left( Y \xrightarrow{c} f_*(1) \right) = (f_*(1) \perp \rightharpoonup Y). \]
since \( c^*(1, f_*(1)) = c^*(f_*(1)) = f_*(1) \perp \). We check that \( i_f \circ e_f = f \), as required.

\[
(i_f \circ e_f)_*(x) = (i_f)_* \left( (e_f)_*(x)^{f_*(1)\perp} \right) = ((e_f)_*(x)^{f_*(1)\perp} \wedge f_*(1)^\perp) = (f_*(x) \wedge f_*(1)^\perp) \vee f_*(1) = f_*(x),
\]
by orthomodularity, using that \( f_*(1) \leq f_*(x) \), since \( x \leq 1 \). This map \( e_f \) is indeed zero-epic by the previous lemma, since:

\[
(e_f)_*(1) = f_*(1) \wedge f_*(1)^\perp = 0.
\]

Next we first observe:

\[
f_*(x \vee f^*(1)) = f_*(x) \wedge f_*(f^*(1)) = f_*(x) \wedge 1 = f_*(x), \quad (*)
\]
since there is a “unit” \( 1 \leq f_*(f^*(1)) \). We use this twice, in the marked equations, in:

\[
(m_f \circ (i_f)^!)_*(x) = (m_f)_* \circ (-)^{f_*(1)\perp} \circ (i_f)^* (x) = (m_f)_* (f^*(1)^\perp \wedge ((f^!)_*(1)^\perp \wedge x^\perp)^\perp) = f_*(f^*(1)^\perp \wedge (f^*(1) \vee x)) \wedge f_*(1)^\perp \overset{(*)}{=} f_*(f^*(1) \vee (f^*(1)^\perp \wedge (f^*(1) \vee x))) \wedge f_*(1)^\perp \overset{(*)}{=} f_*(f^*(1) \vee x) \wedge f_*(1)^\perp \overset{(*)}{=} f_*(x) \wedge f_*(1)^\perp = (e_f)_*(x).
\]

The map \( m_f \) is zero-epic since:

\[
(m_f)_*(1, f^*(1)) = (m_f)_* (f^*(1)^\perp) = f_*(f^*(1)^\perp) \wedge f_*(1)^\perp \overset{(*)}{=} f_*(f^*(1) \vee f^*(1)^\perp) \wedge f_*(1)^\perp = f_*(1) \wedge f_*(1)^\perp = 0.
\]

Similarly one shows that \( m_f \) is zero-monic.

For the record, inverse and direct images are described explicitly.

**Lemma 10** For a map \( f : X \to Y \) in **OMLatGal** the associated inverse and direct images are:

\[
\begin{align*}
\text{KSub}(Y) & \xrightarrow{f^{-1}} \text{KSub}(X) & \text{KSub}(X) & \xrightarrow{3f} \text{KSub}(Y) \\
(\downarrow b \to Y) & \xrightarrow{(\downarrow f^*(b^\perp) \to X)} & (\downarrow a \to X) & \xrightarrow{((f_*(a))^\perp \to Y)}
\end{align*}
\]
For \( f : X \to Y \) and \( b \in Y \), we have, using the formulation for pullback of kernels from Section 2 (or [19, Lemma 2.4]) and Lemma 9 above,

\[
\begin{align*}
f^{-1}(\downarrow b \to Y) &= \ker(\text{coker}(\downarrow b \to Y) \circ f) \\
&= \ker((Y \to \downarrow c) \circ f), \quad \text{for } c = b_*(1_{\downarrow b}) = (1_{\downarrow b})^\perp = b^\perp \\
&= \downarrow a \to X, \quad \text{for } a = (\lceil c \rceil \circ f)^*(1_{\downarrow b}) = f^*(c_* (1_{\downarrow c})^\perp) \\
&= f^*(c^\perp) = f^*(c) = f^*(b^\perp) \\
&= \downarrow f^*(b^\perp) \to X.
\end{align*}
\]

For \( \exists f \) we also use Lemma 9 in:

\[
\begin{align*}
\exists f(\downarrow a \to X) &= \text{Im}(f \circ (\downarrow a \to X)) \\
&= \downarrow b \to Y, \quad \text{where } b = (f \circ a)_*(1_{\downarrow a})^\perp = f_*(a_*(1_{\downarrow a})^\perp) \\
&= f_*(a^\perp)^\perp \\
&= \downarrow (f_*(a)^\perp) \to Y.
\end{align*}
\]

Theorem 7 says that the mapping \( X \to \text{KSub}(X) \) is surjective. Here we shall show that it is an injective homomorphism of orthomodular lattices reflecting the order, so that it is an isomorphism in the category \( \text{OMLatGal} \).

**Proposition 11** Each dagger mono \( a : \downarrow a \to X \) from Lemma 9 for \( a \in X \), is actually a dagger kernel. This yields an isomorphism of orthomodular lattices

\[
X \cong \text{KSub}(X), \quad \text{namely } a \mapsto (\downarrow a \to X).
\]

It is natural in the sense that for \( f : X \to Y \) in \( \text{OMLatGal} \) the following squares commute by Lemma 10.

\[
\begin{array}{ccc}
X & \xrightarrow{\perp \circ f_*} & Y \\
\cong & & \cong \\
\text{KSub}(X) & \xrightarrow{\exists f} & \text{KSub}(Y) \\
\downarrow \cong & & \downarrow \cong \\
& \xrightarrow{f^{-1}} & \text{KSub}(X)
\end{array}
\]

**Proof** We first check that \( a : \downarrow a \to X \) is indeed a kernel, namely of its cokernel \( \text{coker}(a) : X \to \downarrow a_*(1) \), see Lemma 8, where \( a_*(1) = a_*(1_{\downarrow a}) = a_*(a) = a^\perp \). Thus, \( \ker(\text{coker}(a)) = \text{coker}(a)^*(1) = \text{coker}(a)^*(1_{\downarrow a}^\perp) = \text{coker}(a)^*(1^\perp) = a^\perp = a \).

Theorem 7 says that the mapping \( X \to \text{KSub}(X) \) is surjective. Here we shall show that it is an injective homomorphism of orthomodular lattices reflecting the order, so that it is an isomorphism in the category \( \text{OMLat} \).

Assume that \( a \leq b \in X \). We can define \( \varphi : \downarrow a \to \downarrow b \) by \( \varphi_*(x) = x^\perp = b \land x^\perp \) and \( \varphi^*(y) = a \land y^\perp \), for \( x \in \downarrow a \) and \( y \in \downarrow b \). Then, clearly, \( y \leq \varphi_*(x) \) iff
\( x \leq \varphi^*(y) \), so that \( \varphi \) is a morphism in \( \text{OMLatGal} \). In order to show \( a \leq b \) in \( \text{KSub}(X) \) we prove \( b \circ \varphi = a \). First, for \( x \in \downarrow a \),

\[
(b \circ \varphi)_*(x) = b_*(\varphi_*(x)^\perp) \\
= b_*(x^\perp)^\perp \\
= b_*(x) \quad \text{because } x \in \downarrow a \subseteq \downarrow b \\
= x^\perp \quad \Rightarrow \\
= a_*(x).
\]

The map \( X \to \text{KSub}(X) \) does not only preserve the order, but also reflects it: if we have an arbitrary map \( \psi: \downarrow a \to \downarrow b \) in \( \text{OMLatGal} \) with \( b \circ \psi = a \), then:

\[
a = a^{\perp \perp} = a_*(a)^\perp = (b \circ \psi)_*(a)^\perp \\
= b_*(\psi_*(a)^{\perp \perp})^\perp \\
= \psi_*(a)^{\perp \perp} \perp \\
= \psi_*(a)^\perp \\
= b \land \psi_*(a) \leq b.
\]

This \( X \to \text{KSub}(X) \) map also preserves \( \perp \), since \( \left( \downarrow a \xrightarrow{a} X \right)^\perp = \ker(a) = (\downarrow b \xrightarrow{b} X) \)

where, according to Theorem 4, \( b = (a^\dagger)^* (1_{\downarrow a}) = a_*(a) = a^\perp \).

It remains to show that the mapping \( X \to \text{KSub}(X) \) preserves finite conjunctions. It is almost immediate that it sends the top element \( 1 \in X \) to the identity map (top) in \( \text{KSub}(X) \). It also preserves finite conjunctions, since the intersection of the kernels \( \downarrow a \to X \) and \( \downarrow b \to X \) is given by \( \downarrow (a \land b) \to X \). Since \( a \land b \leq a, b \) there are appropriate maps \( \downarrow (a \land b) \to \downarrow a \) and \( \downarrow (a \land b) \to \downarrow b \). Suppose that we have maps \( k \to \downarrow a \) and \( k \to \downarrow b \), where \( k: \downarrow f^*(1) \to X \) is a kernel of \( f: X \to Y \). Since, as we have seen, the order is reflected, we get \( f^*(1) \leq a, b \), and thus \( f^*(1) \leq a \land b \), yielding the required map \( \downarrow f^*(1) \to \downarrow (a \land b) \). \( \square \)

The adjunction \( \exists f \vdash f^{-1} \) that exists in arbitrary dagger kernel categories (see Section 2 or [19, Proposition 4.3]) boils down in our example \( \text{OMLatGal} \) to the adjunction between \( f^* \vdash f_* \) in the definition of morphisms in \( \text{OMLatGal} \), since:

\[
\exists_f (\downarrow a \to X) \leq (\downarrow b \to Y) \iff (\downarrow f_*(a)^\perp \to Y) \leq (\downarrow b \to Y) \\
\iff f_*(a)^\perp \leq b \\
\iff b^\perp \leq f_*(a) \\
\iff a \leq f^*(b^\perp) \\
\iff (\downarrow a \to X) \leq (\downarrow f^*(b^\perp) \to X) \\
\iff (\downarrow a \to X) \leq f^{-1}(\downarrow b \to X).
\]
Moreover, the Sasaki hook \( \supset \) and and-then operators \& defined categorically in [19, Proposition 6.1], see Section 2, amount in OMLatGal to their usual definitions in the theory of orthomodular lattices, see e.g. [11, 26]. This will be illustrated next. We use the “effect” \( \mathfrak{E}(\downarrow a \to X) = a \circ a^\dagger : X \to X \) associated with a kernel in:

\[
(\downarrow a \to X) \supset (\downarrow b \to X) \overset{\text{def}}{=} \mathfrak{E}(\downarrow a \to X)^{-1}(\downarrow b \to X) = (\downarrow c \to X),
\]

where, according to the description of inverse image \((-)^{-1}\) in the previous lemma,

\[
c = (a \circ a^\dagger)^*(b^\parallel) = a_*(a^*(b^\perp)^\parallel) = (a \wedge (a \wedge b)^\perp)^\perp = a^\perp \vee (a \wedge b) = a \supset b.
\]

Similarly for and-then \&:

\[
(\downarrow a \to X) & (\downarrow b \to X) \overset{\text{def}}{=} \exists_{\mathfrak{E}(\downarrow b \to X)}(\downarrow a \to X) = (\downarrow c \to X),
\]

where the description of direct image from Lemma 10 yields:

\[
c = (b \circ b^\dagger)_*(a^\parallel) = b_*(b^*(a^\perp)^\parallel) = (b \wedge (b \wedge a)^\perp)^\parallel = b \wedge (b^\perp \vee a) = a \& b.
\]

These \& and \( \supset \) are, by construction, related via an adjunction (see also [11, 7]).

Also one can define a weakest precondition modality \([f]\) from dynamic logic in this setting: for \( f : X \to Y \) and \( y \in Y \), put:

\[
[f](y) \overset{\text{def}}{=} f^*(y^\perp).
\]

for “\( y \) holds after \( f \)”. This operation \([f](\cdot)\) preserves conjunctions, as usual.

An element \( a \in X \) yields a test operation \( a? = \mathfrak{E}(a) = a \circ a^\dagger \). Then one can recover the Sasaki hook \( a \supset b \) via this modality as \([a]?b\), and hence complement \( a^\perp \) as \([a]?0\), see also e.g. [2].

There is another isomorphism of interest in this setting.

**Lemma 12** Let \( 2 = \{0, 1\} \) be the 2-element Boolean algebra, considered as an orthomodular lattice \( 2 \in \text{OMLatGal} \). For each orthomodular lattice \( X \), there is an isomorphism (of sets):

\[
X \overset{\cong}{\longrightarrow} \text{OMLatGal}(2, X)
\]

which maps \( a \in X \) to \( \overline{a} : 2 \to X \) given by:

\[
\overline{a}(w) = \begin{cases} 1 & \text{if } w = 0 \\ a^\perp & \text{if } w = 1 \end{cases} \quad \overline{a}(x) = \begin{cases} 1 & \text{if } x \leq a^\perp \\ 0 & \text{otherwise}. \end{cases}
\]

This isomorphism is natural: for \( f : X \to Y \) one has:

\[
\begin{array}{ccc}
X & \overset{\cong}{\longrightarrow} & \text{OMLatGal}(2, X) \\
\downarrow \overset{\perp \circ f}{\cong} & & \downarrow \overset{f \circ \perp}{\cong} \\
\text{OMLatGal}(2, X) & \overset{\cong}{\longrightarrow} & \text{OMLatGal}(2, Y)
\end{array}
\]
The thing to note is that for a map \( g : 2 \rightarrow X \) in \( \text{OMLatGal} \) we have \( g^*(0) = 1 \) because \( g^* : 2^{\text{op}} \rightarrow X \) is a right adjoint. Hence we can only choose \( g^*(1) \in X \). Once this is chosen, the left adjoint \( g^* : X \rightarrow 2^{\text{op}} \) is completely determined, namely as \( 1 \leq g^*(x) \) iff \( x \leq g^*(1) \).

As to naturality, it suffices to show:

\[
(f \circ \exists)_*(1) = f_*(\exists_*(1)) = f_*(a^{\perp\perp}) = f_*(a)^{\perp\perp} = (\perp \circ f_*(a))_*(1).
\]

By combining the previous two results we obtain a way to classify (kernel) subobjects, like in a topos \([29]\), but with naturality working in the opposite direction. In \([19]\) a similar structure was found in the category \( \text{Rel} \) of sets and relations, and also in the dagger kernel category associated with a Boolean algebra.

**Corollary 13** The 2-element lattice \( 2 \in \text{OMLatGal} \) is an “opclassifier”: there is a “characteristic” isomorphism:

\[
\text{KSub}(X) \xrightarrow{\text{char}} \text{OMLatGal}(2, X).
\]

which is natural: \( \text{char} \circ \exists_f = f \circ \text{char}. \)

We conclude our investigation of the category \( \text{OMLatGal} \) with the following observation.

**Proposition 14** The category \( \text{OMLatGal} \) has (finite) dagger biproducts \( \oplus \). Explicitly, \( X_1 \oplus X_2 \) is the Cartesian product of (underlying sets of) orthomodular lattices, with coprojection \( \kappa_1 : X_1 \rightarrow X_1 \oplus X_2 \) defined by \( (\kappa_1)_*(x) = (x^{\perp}, 1) \) and \( (\kappa_1)_*(x, y) = x^{\perp} \). The dual product structure is given by \( \pi_i = (\kappa_i)^\uparrow \).

**Proof** Let us first verify that \( \kappa_1 \) is a well-defined morphism of \( \text{OMLatGal} \), i.e. that \( (\kappa_1)^* \vdash (\kappa_1)_* \):

\[
\frac{z \leq x^{\perp} = (\kappa_1)^*(x, y)}{x \leq z^{\perp}} \quad \frac{x \leq z^{\perp}}{(x, y) \leq (z^{\perp}, 1) = (\kappa_1)_*(z)}
\]

Also, \( \kappa_1 \) is a dagger mono since:

\[
(\kappa_1)^*((\kappa_1)_*(x)) = (\kappa_1)^*((x^{\perp}, 1)) = (\kappa_1)^*(x, 0) = x^{\perp}.
\]

Likewise, there is a dagger mono \( \kappa_2 : X_2 \rightarrow X_1 \oplus X_2 \). For \( i \neq j \), one finds that \( (\kappa_j)^\uparrow \circ \kappa_i \) is the zero morphism.
In order to show that $X_1 \oplus X_2$ is indeed a coproduct, suppose that morphisms $f_i: X_i \to Y$ are given. We then define the cotuple $[f_1, f_2]: X_1 \oplus X_2 \to Y$ by $[f_1, f_2]_*(x_1, x_2) = (f_1)_*(x_1) \land (f_2)_*(x_2)$ and $[f_1, f_2]^*(y) = (f_1^*(y), f_2^*(y))$. Clearly, $[f_1, f_2]^* \dashv [f_1, f_2]_*$, and:

\[
([f_1, f_2] \circ \kappa_1)_*(x) = [f_1, f_2]_*((\kappa_1)_*(x)^\perp) = [f_1, f_2]_*((x^\perp, 1)^\perp) = (f_1)_*(x) \land (f_2)_*(0) = (f_1)_*(x) \land 1 = (f_1)_*(x).
\]

so that $[f_1, f_2] \circ \kappa_1 = f_1$. Likewise, $[f_1, f_2] \circ \kappa_2 = f_2$. Moreover, if $g: X_1 \oplus X_2 \to Y$ also satisfies $g \circ \kappa_i = f_i$, then:

\[
[f_1, f_2]_*(x_1, x_2) = (f_1)_*(x_1) \land (f_2)_*(x_2) = g_*((\kappa_1)_*(x_1)^\perp) \land g_*((\kappa_2)_*(x_2)^\perp) = g_*((x_1^\perp, 1)^\perp) \land g_*((1, x_2^\perp)^\perp) = g_*((x_1, 0) \land g_*((0, x_2) = g_*((x_1, 0) \lor (0, x_2)) = g_*((x_1, x_2)).
\]

\[\square\]

### 3.1 From dagger kernel categories to orthomodular lattices

The aim in this subsection is to show that for a dagger kernel category $\mathbf{D}$ the kernel subobject functor $\text{KSub}(-)$ is a functor $\mathbf{D} \to \mathbf{OMLatGal}$. On a morphism $f: X \to Y$ of $\mathbf{D}$, define $\text{KSub}(f): \text{KSub}(X) \to \text{KSub}(Y)$ by:

\[
\text{KSub}(f)_*(m) = (\exists f(m))^\perp \quad \text{KSub}(f)^*(n) = f^{-1}(n^\perp).
\]

Then indeed $\text{KSub}(f)^* \dashv \text{KSub}(f)_*$:

\[
\frac{n \leq (\exists f(m))^\perp = \text{KSub}(f)_*(m)}{\exists f(m) \leq n^\perp} \quad \frac{m \leq f^{-1}(n^\perp) = \text{KSub}(f)^*(n)}{m \leq f^{-1}(n^\perp)}
\]

The functor $\text{KSub}(-)$ preserves the relevant structure. This requires the following auxiliary result.

**Lemma 15** In a dagger kernel category, for any kernel $k: K \to X$ in $\text{KSub}(X)$, there is an order isomorphism $\text{KSub}(K) \cong \downarrow k \subseteq \text{KSub}(X)$.
Proof The direction \( \text{KSub}(K) \to k \) of the desired bijection is given by \( m \mapsto k \circ m \). This is well-defined since kernels are closed under composition. The other direction \( \uparrow k \to \text{KSub}(K) \) is \( n \mapsto \varphi = k^\dagger \circ n \), where \( n = k \circ \varphi \). One easily checks that these maps are each other’s inverse, and preserve the order. \( \square \)

**Theorem 16** Let \( D \) be a dagger kernel category. The functor \( \text{KSub} : D \to \text{OMLatGal} \),

(a) is a map of dagger kernel categories;

(b) preserves (finite) biproducts, in case they exist in \( D \).

**Proof** Preservation of daggers follows because \( f^{-1} \) and \( \exists_f \) are inter-expressible, see Section [2] and [19, Proposition 4.3]:

\[
\text{KSub}(f^\dagger)_*(n) = (\exists f_!(n))^\perp = f^{-1}(n^\perp) = \text{KSub}(f)^*(n) = (\text{KSub}(f)^\dagger)_*(n).
\]

Preservation of the zero object is easy: \( \text{KSub}(0) = \{0\} = 0 \).

Next, let \( k : K \to X \) be the kernel of a morphism \( f : X \to Y \) in \( D \). We recall from [19, Corollary 2.5 (ii)] that this kernel \( k \) can be described as inverse image \( k = f^{-1}(0) = f^{-1}(1^\perp) = \text{KSub}(f)^*(1) \). Hence by Lemmas [15 and 6] we have the isomorphism on the left in:

\[
\begin{array}{ccc}
\text{KSub}(K) & \xrightarrow{k \circ} & \text{KSub}(X) \\
\downarrow k & & \downarrow k \\
\text{KSub}(k) & \xrightarrow{\text{KSub}(f)} & \text{KSub}(Y)
\end{array}
\]

It yields a commuting triangle since for \( n \in \text{KSub}(K) \),

\[
\text{KSub}(k)_*(n) = \exists_k(n)^\perp = (k \circ n)^\perp = k_*(k \circ n).
\]

Similarly for \( m \in \text{KSub}(X) \),

\[
k \circ \text{KSub}(k)^*(m) = k \circ k^{-1}(m^\perp) = k \land m^\perp = k^* (m).
\]

For (b), it suffices to prove that \( \text{KSub}(\kappa_i) : \text{KSub}(X_i) \to \text{KSub}(X_1 \oplus X_2) \) is a coproduct in \( \text{OMLatGal} \). Let morphisms \( f_i : \text{KSub}(X_i) \to Y \) in \( \text{OMLatGal} \) be given. Define a cotuple \([f_1, f_2] : \text{KSub}(X_1 \oplus X_2) \to Y \) by

\[
[f_1, f_2]_*(m) = (f_1)_*(\exists_{\pi_1}(m)) \land (f_2)_*(\exists_{\pi_2}(m)),
\]

\[
[f_1, f_2]^*(y) = \pi_1^{-1}(((f_1)^*(y)) \land \pi_2^{-1}((f_2)^*(y))
\]

Indeed \([f_1, f_2]^* \models [f_1, f_2]_*\):

\[
y \leq (f_1)_*(\exists_{\pi_1}(m)) \land (f_2)_*(\exists_{\pi_2}(m)) = [f_1, f_2]_*(m)
\]

\[
y \leq (f_1)_*(\exists_{\pi_1}(m)) \quad \exists_{\pi_1}(m) \leq (f_1)^*(y)
\]

\[
m \leq \pi_1^{-1}((f_1)^*(y)) \quad \pi_1^{-1}((f_1)^*(y)) \leq (f_1)_*(m)
\]

\[
m \leq \pi_2^{-1}((f_2)^*(y)) \quad \pi_2^{-1}((f_2)^*(y)) \leq (f_2)_*(m)
\]

\[
m \leq [f_1, f_2]^*(y)
\]
This morphism \([f_1, f_2]: \text{KSub}(X_1 \oplus X_2) \to Y\) of \text{OMLatGal} satisfies:

\[
([f_1, f_2]) \circ \text{KSub}(\kappa_1), (m) = [f_1, f_2], (\text{KSub}(\kappa_1), (m)^\perp)
\]

\[
= [f_1, f_2], (\exists_{\kappa_1}(m))
\]

\[
= (f_1), (\exists_{\kappa_1}(m)) \land (f_2), (\exists_{\kappa_1}(m))
\]

\[
= (f_1), (\exists_{\kappa_2 \circ \kappa_1}(m)) \land (f_2), (\exists_{\kappa_2 \circ \kappa_1}(m))
\]

\[
= (f_1), (\exists_{\kappa_2}(m)) \land (f_2), (\exists_{\kappa_2}(m))
\]

\[
= (f_1), (m) \land (f_2), (0)
\]

\[
= (f_1), (m) \land 1
\]

\[
= (f_1), (m).
\]

Towards uniqueness, assume \(g: \text{KSub}(X_1 \oplus X_2) \to Y\) in \text{OMLatGal} also satisfies \(g \circ \text{KSub}(\kappa_1) = f_1\). Then:

\[
[f_1, f_2], (m) = (f_1), (\exists_{\pi_1}(m)) \land (f_2), (\exists_{\pi_2}(m))
\]

\[
= g, (\exists_{\kappa_1}, \exists_{\pi_1}(m)) \land g, (\exists_{\kappa_2}, \exists_{\pi_2}(m))
\]

\[
= g, (\exists_{\kappa_1 \circ \pi_1}(m) \lor \exists_{\kappa_2 \circ \pi_2}(m))
\]

This last step needs justification. By Theorem \(\ref{thm:main} \) \(m \in \text{KSub}(X_1 \oplus X_2)\) can be written as \(m = ((x_1, x_2) \to X_1 \oplus X_2)\) for certain \(x_i \in X_i\). Then, by Lemma \(\ref{lem:translation} \)

\[
\exists_{\kappa_1 \circ \pi_1}(m) \lor \exists_{\kappa_2 \circ \pi_2}(m)
\]

\[
= (\exists((\kappa_1 \circ \pi_1)), ((x_1, x_2), \perp) \lor (\kappa_2 \circ \pi_2), ((x_1, x_2), \perp)) \to X_1 \oplus X_2
\]

\[
= ((x_1, x_2) \to X_1 \oplus X_2)
\]

\[
= m,
\]

since:

\[
(\kappa_1 \circ \pi_1), ((x_1, x_2), \perp) = (\kappa_1), ((\pi_1), ((x_1, x_2), \perp)) \perp
\]

\[
= (\kappa_1), (x_1, x_2, \perp) \perp
\]

\[
= (x_1, 1) \perp
\]

\[
= (x_1, 0).
\]

At this stage we conclude that these \text{KSub} functors yield a well-behaved translation of a dagger kernel category into a collection of orthomodular lattices, indexed by the objects of the category. For the special case \(\mathbf{D} = \text{OMLatGal}\), the functor \(\text{KSub}: \mathbf{D} \to \text{OMLatGal}\) is the identity, up to isomorphism, by Proposition \(\ref{prop:identity} \). A translation in the other direction, from orthomodular lattices to dagger kernel categories will be postponed until after the next section, after we have seen the translation from Foulis semigroups to orthomodular lattices.

In the remainder of this section we shall briefly consider two special subcategories of \text{OMLatGal}, namely with Boolean and with complete orthomodular lattices.
3.2 The Boolean case

Let $\text{BoolGal} \hookrightarrow \text{OMLatGal}$ be the full subcategory of Boolean algebras with (antitone) Galois connections between them. We recall that a Boolean algebra can be described as an orthomodular lattice that is distributive.

The main (and only) result of this subsection is simple.

**Proposition 17** The category $\text{BoolGal}$ inherits dagger kernels and biproducts from $\text{OMLatGal}$. Moreover, as a dagger kernel category it is Boolean.

**Proof** An arbitrary map $f : X \to Y$ in $\text{BoolGal}$ has a kernel $\downarrow f^*(1)$ as in Theorem 7 for orthomodular lattices because the downset $\downarrow f^*(1)$ is a Boolean algebra. Similarly, the biproducts from Proposition 14 also exist in $\text{BoolGal}$ because $X \oplus Y$ is a Boolean algebra if $X$ and $Y$ are Boolean algebras.

For each $X \in \text{BoolGal}$ one has $\text{KSub}(X) \cong X$ so that $\text{KSub}(X)$ is a Boolean algebra. Hence $\text{BoolGal}$ is a Boolean dagger kernel category by [19, Theorem 6.2]. □

Boolean algebras thus give rise to (Boolean) dagger kernel categories on two different levels: the “large” category $\text{BoolGal}$ of all Boolean algebras is a dagger kernel category, but also each individual Boolean algebra can be turned into a “small” dagger kernel category, see [19, Proposition 3.5].

3.3 Complete orthomodular lattices

We shall write $\text{OMSupGal} \hookrightarrow \text{OMLatGal}$ for the full subcategory of orthomodular lattices that are complete, i.e. that have joins $\bigvee U$ (and thus also meets $\bigwedge U$) of all subsets $U$ (and not just the finite ones). Notice that the functor $\text{KSub}: \mathcal{D} \to \text{OMLatGal}$ from Theorem 16 is actually a functor $\text{KSub}: \mathcal{D} \to \text{OMSupGal}$ for $\mathcal{D} = \text{Rel}, \text{PInj}, \text{Hilb}$.

A morphism $f : X \to Y$ in $\text{OMSupGal}$ is completely determined by either $f_* : X^{\text{op}} \to Y$ preserving all meets, or by $f^* : Y \to X^{\text{op}}$ preserving all joins.

This forms the basis for the next result.

**Proposition 18** The forgetful functor $U : \text{OMSupGal} \to \text{Sets}$ given by $X \mapsto X$ on objects and $f \mapsto f_* \circ \bot$ on morphisms has a left adjoint $F$ given by $F(A) = \mathcal{P}A$, with $F(g)(U \subseteq A) = \neg \bigsqcup g(U) = \neg \{ g(a) \mid a \in U \}$ and $F(g)^*(V \subseteq B) = g^{-1}(\neg V) = \{ a \mid g(a) \not\in V \}$, for $g : A \to B$ in $\text{Sets}$.

**Proof** For $A \in \text{Sets}$ and $X \in \text{OMSupGal}$ there is a bijective correspondence:

$$
\begin{array}{ccc}
\mathcal{P}A & \xrightarrow{f} & X \\
A & \xrightarrow{g} & X
\end{array}
$$

in $\text{OMSupGal}$

in $\text{Sets}$
given by \( \overline{f}(a) = f_*(\{a\}) \) and \( \overline{g}(U) = \bigwedge_{a \in U} g(a) \) with \( \overline{g}(x) = \{ a \in A \mid g(a) \leq x \} \). Then:

\[
\begin{align*}
x \leq \overline{g}(U) &= \bigwedge_{a \in U} g(a) \\
&\iff \forall a \in U, x \leq g(a) \\
&\iff \forall a \in U, g(a) \leq x \\
&\iff U \subseteq \{ a \in A \mid g(a) \leq x \} = \overline{g}(x).
\end{align*}
\]

Further,

\[
\begin{align*}
\overline{g}(a) &= \overline{g}_*(\{a\}) = (\bigwedge_{b \in \{a\}} g(b)) = g(a) = g(a) \\
\overline{f}(U) &= \bigwedge_{a \in U} f_*(\{a\}) = \bigwedge_{a \in U} f_*(\{a\}) = f_*(U) \\
\overline{f}(x) &= \{ a \mid \overline{f}(a) \leq x \} = \{ a \mid f_*(\{a\}) \leq x \} = \{ a \mid x \leq f_*(\{a\}) \}
\end{align*}
\]

The left adjoint \( F \) of this adjunction between \( \text{OMSupGal} \) and \( \text{Sets} \) factors via the graph functor \( G : \text{Sets} \to \text{Rel} \), as in:

\[
\begin{array}{ccc}
\text{Sets} & \xrightarrow{\mathcal{G}} & \text{Rel} \\
\downarrow & \searrow \mathcal{KSub} & \swarrow \\
& \text{OMSupGal}
\end{array}
\]

It is not hard to see that the kernels from Theorem 7 and biproducts \( \oplus \) from Proposition 14 also exist in \( \text{OMSupGal} \). For instance, the join of a subset \( U \subseteq X \oplus Y \) is given as pair of joins:

\[
\bigvee U = (\bigvee \{ x \mid \exists y, (x, y) \in U \}, \bigvee \{ y \mid \exists x, (x, y) \in U \}).
\]

Hence \( \text{OMSupGal} \) is also a dagger kernel category with dagger biproducts.

### 4 Foulis semigroups and dagger kernel categories

In this section we shall relate dagger kernel categories and Foulis semigroups. Without a definition yet, we first illustrate that these Foulis semigroups arise quite naturally in the context of kernel dagger categories.

In every category \( \mathbf{D} \) the homset \( \text{Endo}(X) = \mathbf{D}(X, X) \) of endomaps \( f : X \to X \) is a monoid (or semigroup with unit), with obvious composition operation \( \circ \) and identity map \( \text{id}_X \) as unit element. If \( \mathbf{D} \) is a dagger category, there is automatically an involution \( (\cdot)\dagger \) on this monoid. If it is moreover a dagger kernel category, every endomap \( s \in \text{Endo}(X) \) yields a self-adjoint idempotent, namely the effect of its kernel:

\[
[s] \overset{\text{def}}{=} \mathcal{E}(\ker(s)) = \ker(s) \circ \ker(s) : X \to X
\]

with the special property that for \( t \in \text{Endo}(X) \),

\[
s \circ t = 0 \iff \exists r \in \text{Endo}(X), t = [s] \circ r.
\]

20
Indeed, if $t = [s] \circ r$, then:

$$s \circ t = s \circ \ker(s) \circ \ker(s) \circ r = 0 \circ \ker(s) \circ r = 0.$$  

Conversely, if $s \circ t = 0$, then there is a map $f$ in $D$ with $\ker(s) \circ f = t$. Hence $t$ satisfies:

$$[s] \circ t = \ker(s) \circ \ker(s) \circ f = \ker(s) \circ f = t.$$  

This structure of an involutive monoid $\langle \operatorname{Endo}(X) \circ, \operatorname{id}, \dagger \rangle$ with such an operation $[-] \colon \operatorname{Endo}(X) \rightarrow \operatorname{Endo}(X)$ has been introduced in the 1960s by Foulis [12, 13, 14] and has since then been studied under the name ‘Baer *-semigroup’ or ‘Foulis semigroup’, see [26, Chapter 5, §§18] for a brief overview.

**Definition 19** A Foulis semigroup consists of a monoid (semigroup with unit) $(S, \cdot, 1)$ together with two endomaps $([-], \dagger) : S \rightarrow S$ satisfying:

1. $1^\dagger = 1$ and $(s \cdot t)^\dagger = t^\dagger \cdot s^\dagger$ and $s^{\dagger \dagger} = s$, making $S$ an involutive monoid;
2. $[s]$ is a self-adjoint idempotent, i.e. satisfies $[s] \cdot [s] = [s] = [s]^\dagger$;
3. $0 \overset{\text{def}}{=} [1]$ is a zero element: $0 \cdot s = 0 = s \cdot 0$;
4. $s \cdot x = 0$ iff $\exists y, x = [s] \cdot y$.

Or, equivalently (see [26, Chapter 5, §§18, Lemma 1]),

$$4'. [0] = 1 \text{ and } s \cdot [s] = 0 \text{ and } t = [[t^\dagger \cdot s^\dagger] \cdot s] \cdot t.$$  

We form a category $\mathbf{Fsg}$ of such Foulis semigroups with monoid homomorphisms that commute with $\dagger$ and $[-]$ as morphisms.

The constructions before this definition show that for each object $X \in D$ of a (locally small) dagger kernel category $D$, the homset $\operatorname{Endo}(X) = D(X, X)$ of endomaps on $X$ is a Foulis semigroup. Functoriality of this construction is problematic: for an arbitrary map $f : X \rightarrow Y$ in $D$ there is a mapping $\operatorname{Endo}(X) \rightarrow \operatorname{Endo}(Y)$, namely $s \mapsto f \circ s \circ f^\dagger : Y \rightarrow X \rightarrow Y$, but it does not preserve the structure of Foulis semigroups, and thus only gives rise to presheaf.

**Proposition 20** For a dagger kernel category $D$, each endo homset $\operatorname{Endo}(X)$, for $X \in D$, is a Foulis semigroup. The mapping $X \mapsto \operatorname{Endo}(X)$ yields a presheaf $D \rightarrow \mathbf{Sets}$. □

The lack of functoriality in this construction is problematic. One possible way to address it is via another notion of morphism between Foulis semigroups, like Galois connections between orthomodular lattices in the category $\mathbf{OMLatGal}$. We shall not go deeper into this issue. Also the possible sheaf-theoretic aspects involved in this situation (see also [16]) form a topic on its own that is not pursued here. We briefly consider some examples.

21
For the dagger kernel category \( \text{Hilb} \) of Hilbert spaces, the set \( \mathcal{B}(H) \) of (bounded/continuous linear) endomaps on a Hilbert space \( H \) forms a Foulis semigroup—but of course also a \( C^* \)-algebra. The associated (Foulis) map \([ - ]; \mathcal{B}(H) \to \mathcal{B}(H)\) maps \( s: H \to H \) to \([ s ]; H \to H\) given by \([ s ]; x \equiv k(k^\dagger(x))\), where \( k \) is the kernel map \( \{ x \mid s(x) = 0 \} \to H \).

For the category \( \text{Rel} \) of sets and relations the endomaps on a set \( X \) are the relations \( R \subseteq X \times X \) on \( X \). The associated \([ R ]; X \times X \) is \( \{(x, x) \mid x \in y, R(x, y)\} \).

An interesting situation arises when we apply the previous proposition to the dagger kernel category \( \text{OMLatGal} \) of orthomodular lattices (with Galois connections between them). One gets that for each orthomodular lattice \( X \) the endo-homset \( \text{Endo}(X) = \text{OMLatGal}(X, X) \) forms a Foulis semigroup. This construction is more than 40 years old, see [12] or e.g. [4] Chapter II, Section 19 or 26 Chapter 5, §§18, where it is described in terms of Galois connections. In the present setting it comes for free, from the structure of the category \( \text{OMLatGal} \). Hence we present it as a corollary, in particular of Proposition 20 and Theorem 19.

**Corollary 21** For each orthomodular lattice \( X \) the set of (Galois) endomaps \( \text{Endo}(X) = \text{OMLatGal}(X, X) \) is a Foulis semigroup with composition as monoid, dagger \(( - )^\dagger\) as involution, and self-adjoint idempotent \([ s ]; X \to X\), for \( s: X \to X \), defined as in (1). Equivalently, \([ s ]; \) can be described via the Sasaki hook \( \circ \) or and-then operator \( \& \):

\[
[s]_*(x) = [s]^*(x) = s^*(1) \supset x^\perp = s^*(1)^\perp \lor (s^*(1) \land x^\perp) = (x & s^*(1))^\perp.
\]

**Proof** We recall from [4] that the operation \([ - ]; \) on endomaps \( s: X \to X \) is defined as \([ s ]; \) \( = \ker(s) \circ \ker(s)^\dagger: X \to X \). In \( \text{OMLatGal} \) one has \( \ker(s) = s^*(1) \)—see Proposition 11—so that:

\[
[s]_*(x) = (\ker(s) \circ \ker(s)^\dagger)_*(x) \\
= (\ker(s)_* \circ s^*(1)^\perp) \\
= s^*(1)_* (s^*(1) \land s^*(1)^\perp(x)^\perp) \\
= (s^*(1) \land (s^*(1) \land x^\perp)^\perp)^\perp \quad \text{by Lemma 10} \\
= s^*(1)^\perp \lor (s^*(1) \land x^\perp).
\]

\[ \square \]

### 4.1 From Foulis semigroups to dagger kernel categories

Each involutive monoid \((S, \cdot, 1, \dagger)\) forms a dagger category with one object, and morphisms given by elements of \( S \). Requirement (4) in Definition 13 says that this category has “semi” kernels, given by \([ - ]; \). Hence it is natural to apply the Karoubi envelope to obtain proper kernels. It turns out that this indeed yields a dagger kernel category.

For a Foulis semigroup as in Definition 13 we thus write \( K^\dagger(S) \) for the dagger Karoubi envelope applied to \( S \) as one-object dagger category. Thus \( K^\dagger(S) \) has self-adjoint idempotents \( s \in S \) as objects, and morphisms \( f: s \to t \) given by elements \( f \in S \) with \( f \cdot s = f = t \cdot f \).
Theorem 22  This $\mathcal{K}^\dagger(S)$ is a dagger kernel category. The mapping $S \mapsto \mathcal{K}^\dagger(S)$ yields a functor $\mathfrak{F}_{SG} \rightarrow \mathcal{DKC}$.

Proof  The zero element $0 = [1] \in S$ is obviously a self-adjoint idempotent, and thus an object of $\mathcal{K}^\dagger(S)$. It is a zero object because for each $s \in \mathcal{K}^\dagger(S)$ there is precisely one map $f: s \rightarrow 0$, namely $0$, because $f = 0 \cdot f = 0$.

For an arbitrary map $f: s \rightarrow t$ in $\mathcal{K}^\dagger(S)$ we claim that there is a dagger kernel of the form:

\[
\begin{array}{ccc}
s \cdot [f] & \overset{s \cdot [f]}{\rightarrow} & s \\
& f & \rightarrow & t
\end{array}
\]

This will be checked in a number of small steps.

- $f \cdot (s \cdot [f]) = (f \cdot s) \cdot [f] = f \cdot [f] = 0$, by $(4')$ in Definition 19.
- By the previous point there is an element $y \in S$ with $s \cdot [f] = [f] \cdot y$. Hence:

\[
[f] \cdot s \cdot [f] = [f] \cdot [f] \cdot y = [f] \cdot y = s \cdot [f]
\]

This equation is very useful. It yields first of all that $s \cdot [f]$ is idempotent:

\[
(s \cdot [f]) \cdot (s \cdot [f]) = (s \cdot [f]) \cdot (s \cdot [f]) = s \cdot s \cdot [f] = s \cdot [f].
\]

This element is also self-adjoint:

\[
(s \cdot [f])^\dagger = ([f] \cdot s \cdot [f])^\dagger = [f]^\dagger \cdot s^\dagger \cdot [f]^\dagger = [f] \cdot s \cdot [f] = s \cdot [f].
\]

Hence $s \cdot [f] \in S$ is a self-adjoint idempotent, and thus an object of $\mathcal{K}^\dagger(S)$.

- $s \cdot [f]: (s \cdot [f]) \rightarrow s$ is also a dagger mono:

\[
(s \cdot [f])^\dagger \cdot (s \cdot [f]) = [f]^\dagger \cdot s^\dagger \cdot s \cdot [f] = [f] \cdot s \cdot [f] = s \cdot [f] = \text{id}_{s \cdot [f]}
\]

- Finally, if $g: r \rightarrow s$ in $\mathcal{K}^\dagger(S)$ satisfies $f \circ g = f \cdot g = 0$, then there is a $y \in S$ with $g = [f] \cdot y$. Then:

\[
s \cdot [f] \cdot g = s \cdot [f] \cdot [f] \cdot y = s \cdot [f] \cdot y = s \cdot g = g.
\]

Hence $g$ is the mediating map $r \rightarrow (s \cdot [f])$, since $(s \cdot [f]) \cdot g = g$. Uniqueness follows because $s \cdot [f]$ is a dagger mono.
As to functoriality, assume \( h : S \rightarrow T \) is a morphism of Foulis semigroups. It yields a functor \( H : \mathcal{K}^{\dagger}(S) \rightarrow \mathcal{K}^{\dagger}(T) \) by \( s \mapsto h(s) \) and \( f \mapsto h(f) \). This \( H \) preserves all the dagger kernel structure because it preserves the Foulis semigroup structure. □

By combining this result with Proposition 20 we have a way of producing new Foulis semigroups from old.

**Corollary 23** Each self-adjoint idempotent \( s \in S \) in a Foulis semigroup \( S \) yields a Foulis semigroup of endo-maps:

\[
\mathcal{E}_{\text{Endo}}(s) = \mathcal{K}^{\dagger}(S)(s,s) = \{ t \in S \mid s \cdot t = t = t \cdot s \},
\]

with composition \( \cdot \), unit \( s \), involution \( \dagger \) and \( [t]_s \overset{\text{def}}{=} s \cdot [t] \cdot s \). The special case \( s = 1 \) yields the original semigroup: \( \mathcal{E}_{\text{Endo}}(1) = S \).

**Proof** We only check the formulation following (1):

\[
[t]_s = \ker(t) \circ \ker(t)^\dagger = s \cdot [t] \cdot (s \cdot [t])^\dagger = s \cdot [t] \cdot [t] \cdot s = s \cdot [t] \cdot s.
\]

□

The posets of kernel subobjects in a dagger kernel category are orthomodular lattices. This applies in particular to the category \( \mathcal{K}^{\dagger}(S) \) and yields a way to construct orthomodular lattices out of Foulis semigroups. We first investigate this lattice structure in more detail, via (isomorphic) subsets of \( S \).

**Lemma 24** Let \( S \) be a Foulis semigroup with self-adjoint idempotent \( s \in S \), considered as object \( s \in \mathcal{K}^{\dagger}(S) \). The subset

\[
K_s \overset{\text{def}}{=} \{ s \cdot [t] \cdot s \mid t \in S \} \subseteq S,
\]

is an orthomodular lattice with the following structure.

- **Order** \( k_1 \leq k_2 \iff k_1 = k_2 \cdot k_1 \)
- **Top** \( 1_s = s = s \cdot [s \cdot 0] \)
- **Orthocomplement** \( k_\perp = s \cdot [k] \)
- **Meet** \( k_1 \wedge k_2 = (k_1 \cdot [k_2] \cdot k_1)^\perp \perp \).

In fact, \( K_s \cong \text{KSub}(s) \).

**Proof** In fact it suffices to prove the last isomorphism \( K_s \cong \text{KSub}(s) \) and use it to translate the orthomodular structure from \( \text{KSub}(s) \) to \( K_s \). Instead we proceed in a direct manner and show that each \( K_s \) is an orthomodular lattice in a number of small consecutive steps, resembling the steps taken in [20, Chapter 5, §§18]. One observation that is used a number of times is:

\[
x \cdot y = 0 \implies y = [x] \cdot y \quad (\ast)
\]

for arbitrary \( x, y \in S \). Indeed, if \( x \cdot y = 0 \), then by requirement (4) in Definition 19 there is a \( z \) with \( y = [x] \cdot z \). But then \( [x] \cdot y = [x] \cdot [x] \cdot z = [x] \cdot z = y \).

Let \( s \in S \) now be a fixed self-adjoint idempotent.
(a). Each \( k \in K_s \) is a self-adjoint idempotent, a dagger kernel \( k: k \to s \), and also an idempotent \( k: s \to s \) in \( K^\dagger(S) \).

Indeed, if \( k = s \cdot [t \cdot s] \), then \( (t \cdot s) \cdot k = t \cdot s \cdot [t \cdot s] = 0 \), so that \( k = [t \cdot s] \cdot k \) by \((*)\). Hence:

\[
k \cdot k = s \cdot [t \cdot s] \cdot k = s \cdot k = k
\]

\[
k^\dagger = ([t \cdot s] \cdot k)^\dagger = ([t \cdot s] \cdot s \cdot [t \cdot s])^\dagger
\]

\[
= [t \cdot s]^\dagger \cdot s^\dagger \cdot [t \cdot s]^\dagger = [t \cdot s] \cdot s \cdot [t \cdot s] = k
\]

\[
k^\dagger \cdot k = k \cdot k = k
\]

\[
k \cdot s = k^\dagger \cdot s^\dagger = (s \cdot k)^\dagger = k^\dagger = k.
\]

Also, \( k: k \to s \) is the kernel of \( t \cdot s: s \to 1 \), using the description of kernels in \( K^\dagger(S) \) from the proof of Theorem \([22]\)

(b). The set \( S \) carries a transitive order \( t \leq r \) iff \( r \cdot t = t \). This \( \leq \) is a partial order on \( K_s \).

Transitivity is obvious: if \( t \leq r \leq q \), then \( r \cdot t = t \) and \( q \cdot r = r \) so that \( q \cdot t = q \cdot r \cdot t = r \cdot t = t \), showing that \( t \leq q \).

Reflexivity \( k \leq k \) holds for \( k \in K_s \) since we have \( k \cdot k = k \) as shown in (a).

For symmetry assume \( k \leq \ell \) and \( \ell \leq k \) where \( k, \ell \in K_s \). Then \( \ell \cdot k = k \) and \( k \cdot \ell = \ell \). Hence \( k = k^\dagger = (\ell \cdot k)^\dagger = k^\dagger \cdot \ell^\dagger = k \cdot \ell = \ell \).

(c). For an arbitrary \( t \in S \) put \( t^\perp \overset{\text{def}}{=} s \cdot [t^\dagger \cdot s] \in K_s \). Hence from (a) we get equations \( t^\perp \cdot t^\perp = t^\perp = (t^\perp)^\dagger \) and \( s \cdot t^\perp = t^\perp = s^\perp = s \) that are useful in calculations.

We will show \( t \leq r \Rightarrow r^\perp \leq t^\perp \) and \( k^\perp \perp = k \) for \( k \in K_s \).

Assume \( t \leq r \), i.e. \( t = r \cdot t \). Then, applying the equation \( y = [[y^\perp \cdot x^\perp] \cdot x] \cdot y \) from requirement (4') in Definition \([19]\) for \( y = [r^\perp \cdot s] \) and \( x = t^\perp \cdot s \) yields:

\[
[r^\perp \cdot s] = [[[[r^\perp \cdot s]^\dagger] \cdot (t^\perp \cdot s)^\dagger] \cdot t^\perp \cdot s] \cdot [r^\perp \cdot s]
\]

\[
= [[[((t^\perp \cdot s) \cdot [r^\perp \cdot s]^\dagger] \cdot t^\perp \cdot s] \cdot [r^\perp \cdot s]
\]

\[
= [[[((r \cdot t)^\dagger \cdot s \cdot [r^\perp \cdot s]^\dagger]] \cdot t^\perp \cdot s] \cdot [r^\perp \cdot s]
\]

\[
= [[[t^\perp \cdot r^\perp \cdot s] \cdot [r^\perp \cdot s]^\dagger] \cdot t^\perp \cdot s] \cdot [r^\perp \cdot s]
\]

\[
= [[[t^\perp \cdot 0]^\dagger] \cdot t^\perp \cdot s] \cdot [r^\perp \cdot s] \quad \text{since } x \cdot [x] = 0
\]

\[
= [[0] \cdot t^\perp \cdot s] \cdot [r^\perp \cdot s]
\]

\[
= [1 \cdot t^\perp \cdot s] \cdot [r^\perp \cdot s]
\]

\[
= [t^\perp \cdot s] \cdot [r^\perp \cdot s].
\]
This gives us what we need to show \( r^\perp \leq t^\perp \):

\[
\begin{align*}
t^\perp \cdot r^\perp &= \ t^\perp \cdot s \cdot [r^\perp \cdot s] \\
&= \ t^\perp \cdot [r^\perp \cdot s] \quad \text{since } t^\perp \in K_s \\
&= \ s \cdot [t^\perp \cdot s] \cdot [r^\perp \cdot s] \\
&= \ s \cdot [r^\perp \cdot s] \quad \text{as we have just seen} \\
&= \ r^\perp .
\end{align*}
\]

Next we notice that
\[
t^{\perp \perp} = s \cdot ([t^\perp]^\dagger \cdot s] = s \cdot ([t^\perp \cdot s]^\dagger \cdot s] = s \cdot ([t^\perp \cdot s] \cdot s],
\]

Requirement (4') in Definition [19] applied to \( t \), says:
\[
s \cdot t = s \cdot ([t^\perp \cdot s]^\perp \cdot s] \cdot t = s \cdot ([t^\perp \cdot s] \cdot s] \cdot t = t^{\perp \perp} \cdot t = t^{\perp \perp} \cdot s \cdot t.
\]

It says that \( s \cdot t \leq t^{\perp \perp} \). In particular, this means \( k \leq k^{\perp \perp} \) for \( k \in K_s \).

Since \((-)^\perp\) reverses the order we get:
\[
t^{\perp \perp \perp} \leq (s \cdot t)^\perp = s \cdot [t^\perp \cdot s] = s \cdot [t^\perp \cdot s] = s \cdot [t^\perp] = t^\perp.
\]

If we finally apply this to \( k \in K_s \), say for \( k = s \cdot (t \cdot s) = (t^\perp)^\perp \) we get:
\[
k^{\perp \perp} = (t^\perp)^{\perp \perp \perp} \leq (t^\perp)^\perp = k.
\]

(d). As motivation for the definition of meet, consider for \( k_1, k_2 \in K_s \) their meet as kernels:
\[
r \overset{\text{def}}{=} k_1 \cdot k_1^{-1}(k_2) \\
&= k_1 \cdot \ker(\coker(k_2) \cdot k_1) \quad \text{see pullback from Section [2]} \\
&= k_1 \cdot \ker((s \cdot [k_2]^\dagger) \cdot k_1) \\
&= k_1 \cdot k_1 \cdot [k_2] \cdot s \cdot k_1 \\
&= k_1 \cdot [k_2] \cdot k_1.
\]

We force this \( r \) into \( K_s \) via double negation and hence define \( k_1 \wedge k_2 = r^{\perp \perp} \). Showing that it is the meet of \( k_1, k_2 \) requires a bit of work.

- We have \( k_1 \cdot r = k_1 \cdot k_1 \cdot [k_2] \cdot k_1] = k_1 \cdot [k_2] \cdot k_1 = r, \) so that \( r \leq k_1 \) and thus also \( k_1 \wedge k_2 = r^{\perp \perp} \leq k_1^{\perp \perp} = k_1 \).
- We first observe that
\[
[k_2] \cdot s \cdot s \cdot r = [k_2] \cdot s \cdot s \cdot k_1 \cdot [k_2] \cdot k_1 = [k_2] \cdot k_1 \cdot [k_2] \cdot k_1 = 0.
\]

Hence by applying \( \dagger \) we get \( (r^\perp \cdot s) \cdot (s \cdot [k_2]) = 0 \). Via \( (s) \) we obtain
\[
\begin{align*}
s \cdot [k_2] &= [r^\perp \cdot s] \cdot s \cdot [k_2],
\end{align*}
\]

and thus also
\[
\begin{align*}
k_2^\perp = s \cdot k_2^\perp = s \cdot [k_2] = s \cdot [r^\perp \cdot s] \cdot s \cdot [k_2] = r^\perp \cdot k_2^\perp.
\end{align*}
\]

This says \( k_2^\perp \leq r^\perp \), from which we get \( k_1 \wedge k_2 = r^{\perp \perp} \leq k_2^{\perp \perp} = k_2 \).
• If also \( \ell \in K_s \) satisfies \( \ell \leq k_1 \) and \( \ell \leq k_2 \), i.e. \( k_1 \cdot \ell = \ell = k_2 \cdot \ell \), then, by Definition 19 (4'),

\[
\begin{align*}
[k_2] \cdot k_1 \cdot \ell &= [k_2] \cdot k_2 \cdot \ell = ( [k_2] \cdot k_2 )^\perp \cdot \ell \\
&= ( k_2 \cdot [k_2] )^\perp \cdot \ell \\
&= ( k_2 \cdot [k_2] )^\perp \cdot \ell \\
&= 0^\perp \cdot \ell \\
&= 0.
\end{align*}
\]

Hence \( \ell = ([k_2] \cdot k_1) \cdot \ell \) by (\ast ) and so \( \ell = k_1 \cdot \ell = s \cdot k_1 \cdot \ell = s \cdot k_1 \cdot [ [k_2] \cdot k_1 ] \cdot \ell = s \cdot r \cdot \ell \). Thus \( s \cdot r \leq r^\perp \perp = k_1 \wedge k_2 \).

(c). We get \( k^\perp \wedge k = 0 \), for \( k \in K_s \), as follows. Since \( k \cdot s \cdot [k] = k \cdot [k] = 0 \) one has \( k^\perp = s \cdot [k] = [k] \cdot s \cdot [k] = [k] \cdot k^\perp \) by (\ast ). Hence:

\[
k^\perp \wedge k = ( k^\perp \cdot [ [k] \cdot k^\perp ] )^\perp \perp = ( k^\perp \cdot [ k^\perp ] )^\perp \perp = 0^\perp \perp = 0.
\]

(f). Finally, orthomodularity holds in \( K_s \). We assume \( k \leq \ell \) (i.e. \( k = \ell \cdot k \)) and \( k^\perp \wedge \ell = 0 \), for \( k, \ell \in K_s \), and have to show \( \ell \leq k \) (i.e. \( \ell = k \cdot \ell \)), and thus \( k = \ell \). To start, \( k = k^\perp = (\ell \cdot k)^\perp = k^\perp \cdot \ell^\perp = k \cdot \ell \), so that \( k \cdot \ell^\perp = k \cdot s \cdot [\ell] = k \cdot [\ell] = k \cdot \ell \cdot [\ell] = k \cdot 0 = 0 \). Using (\ast ) yields \( \ell^\perp = [k] \cdot \ell^\perp = [k] \cdot s \cdot [\ell] \), and also \( \ell^\perp = (\ell^\perp)^\perp = ([k] \cdot s \cdot [\ell])^\perp = [\ell^\perp \cdot s^\perp \cdot [k^\perp \perp \cdot [ k^\perp \perp ] = [k] \cdot k^\perp \perp . \) Hence:

\[
k^\perp \cdot \ell = k^\perp \cdot \ell^\perp = k^\perp \cdot s \cdot [\ell^\perp] = k^\perp \cdot [\ell^\perp] \\
= k^\perp \cdot [ [\ell] \cdot k^\perp ] \\
\leq ( k^\perp \cdot [ [\ell] \cdot k^\perp ] )^\perp \perp \\
= k^\perp \wedge \ell \\
= 0.
\]

By (\ast ) we get \( \ell = [k^\perp] \cdot \ell \) so that \( \ell = s \cdot \ell = s \cdot [k^\perp] \cdot \ell = k^\perp \perp \perp \cdot \ell = k \cdot \ell \), as required to get \( \ell \leq k \).

Finally we need to show \( K_s \cong \text{KSub}(s) \). As we have seen in (a), each \( k \in K_s \) yields (an equivalence class of) a kernel \( k : k \to s \). Conversely, each kernel \( \ker(f) = s \cdot [f] = s \cdot [f \cdot s] \) of a map \( f : s \to t \) in \( \mathcal{K}^1(S) \)—see the proof of Theorem 22—is an element of \( K_s \). This yields an order isomorphism: if \( k_1 \leq k_2 \) for \( k_1, k_2 \in K_s \), then \( k_1 = k_2 \cdot k_1 \) so that we get a commuting triangle:

\[
\begin{array}{c}
\xrightarrow[k_1 \cdot k_1 \cdot k_2 \cdot k_2 \cdot f = k_1, & k_2 \cdot k_1 \cdot k_2 \cdot f = f = k_1, showing that k_1 \leq k_2 in K_s \end{array}
\]

showing that \( k_1 \leq k_2 \) in \( \text{KSub}(s) \). Conversely, if there is an \( f : k_1 \to k_2 \) with \( k_2 \cdot f = k_1 \), then \( k_2 \cdot k_1 = k_2 \cdot k_2 \cdot f = k_2 \cdot f = k_1 \), showing that \( k_1 \leq k_2 \) in \( K_s \). \( \Box \)
4.2 Generators

Recall that a generator in a category is an object \( I \) such that for each pair of maps \( f, g: X \to Y \), if \( f \circ x = g \circ x \) for all \( x: I \to X \), then \( f = g \). Every singleton set is a generator in \( \text{Sets} \), and also in \( \text{Rel} \). The complex numbers \( \mathbb{C} \) form a generator in the category \( \text{Hilb} \) of Hilbert spaces of \( \mathbb{C} \). And the two-element orthomodular lattice is a generator in \( \text{OMLatGal} \) by Lemma 12.

We shall write \( \text{DKCg} \hookrightarrow \text{DKC} \) for the subcategory of dagger kernel categories with a given generator, and with morphisms preserving the generator, up-to-isomorphism.

**Lemma 25** The dagger kernel category \( \mathcal{K}^\dagger(S) \) associated with a Foulis semigroup has the unit \( 1 \in S \) as generator. The functor \( \text{Fsg} \to \text{DKC} \) from Theorem 22 restricts to \( \text{Fsg} \to \text{DKCg} \).

**Proof** Assume \( f, g: s \to t \) in \( \mathcal{K}^\dagger(S) \) with \( f \circ x = g \circ x \) for each map \( x: 1 \to s \). Then, in particular for \( x = s \) we get \( f = f \circ s = g \circ s = g \). Every morphism \( h: S \to T \) of Foulis semigroups satisfies \( h(1) = 1 \), so that the induced functor \( \mathcal{K}^\dagger(S) \to \mathcal{K}^\dagger(T) \) preserves the generator. \( \Box \)

**Lemma 26** The mapping \( D \mapsto \text{KSub}(I) \) yields a functor \( \text{DCKg} \to \text{OMLat} \).

**Proof** If \( F: D \to E \) is a functor in \( \text{DCKg} \), then one obtains a mapping \( \text{KSub}_D(I) \to \text{KSub}_E(I) \) by:

\[
\begin{array}{ccc}
\left( M \xrightarrow{m} I \right) & \longrightarrow & \left( FM \xrightarrow{Fm} FI \right. \xrightarrow{\cong} I) \\
\end{array}
\]

Since all the orthomodular structure in kernel posets \( \text{KSub}(X) \) is defined in terms of kernels and daggers, it is preserved by \( F \). \( \Box \)

By composition we obtain the original (“old”) way to construct an orthomodular lattice out of a Foulis semigroup, see [14].

**Corollary 27** The composite functor \( \text{Fsg} \to \text{DCKg} \to \text{OMLat} \) maps a Foulis semigroup \( S \) to the orthomodular lattice \( [S] = \{ \|t\| \mid t \in S \} = K_1 \cong \text{KSub}(1) \) from Lemma 24, over the generator 1. \( \Box \)

In the reverse direction we have seen in Corollary 21 that the set \( \text{Endo}(X) \) of (Galois) endomaps on an orthomodular lattice \( X \) is a Foulis semigroup, but functoriality is problematic. However, we can now solve a problem that was left open in [19], namely the construction of a dagger kernel category out of an orthomodular lattice \( X \). Theorem 22 says that the dagger Karoubi envelope \( \mathcal{K}^\dagger(\text{Endo}(X)) \) is a dagger kernel category. Its objects are self-adjoint idempotents \( s: X \to X \), and its morphisms \( f: (X, s) \to (X, t) \) are maps \( f: X \to X \) in \( \text{OMLatGal} \) with \( t \circ f = f = f \circ s \).
5 Conclusions

There is a relatively recent line of research applying categorical methods in quantum theory, see for instance [5, 1, 32, 8, 20, 6]. This paper fits into this line of work, with a focus on quantum logic (following [19]), and establishes a connection to early work on quantum structures. It constructs new (dagger kernel) categories of orthomodular lattices and of self-adjoint idempotents in Foulis semigroups (also known as Baer *-semigroups). These categorical constructions are shown to generalise translations between orthomodular lattices and Foulis semigroups from the 1960s. They provide a framework for the systematic study of quantum (logical) structures.

The current (categorical logic) framework may be used to address some related research issues. We mention three of them.

- As shown, the category \( \text{OMLatGal} \) of orthomodular lattices and Galois connections has (dagger) kernels and biproducts \( \oplus \). An open question is whether it also has tensors \( \otimes \), to be used for the construction of (logics of) compound systems. The existence of such tensors is a subtle matter, given the restrictions described in [30].

- A dagger kernel category gives rise to not just one orthomodular lattice (or Foulis semigroup), but to a collection, indexed by the objects of the category, see for instance the presheaf description in Proposition 20. The precise, possibly sheaf-theoretic (see [16]), nature of this indexing is not fully understood yet.

- So-called effect algebras have been introduced as more recent generalisations of orthomodular lattices, see [10] for an overview. An open question is how such quantum structures relate to the present approach.
