We derive quantum electrodynamics corrections to the fine structure in three-electron atomic systems at \( m \alpha^6 \) and \( m \alpha^7 \ln \alpha \) orders and present their numerical evaluations for the Li atom and Be\(^+\) ion.

PACS numbers: 31.30.J-, 31.15.ac, 32.10.Hq

I. INTRODUCTION

The fine splitting is a difference between energies of \( P_{3/2} \) and \( P_{1/2} \) states. For hydrogenic systems it can be obtained from the Dirac equation, while for many electron systems one needs quantum electrodynami (QED) theory to consistently describe correlations with relativistic effects. The most common many-electron Dirac-like methods \([1–4]\) are able to achieve two significant digits at most, while experimental precision is about 6 significant digits \([5, 6]\). A much more accurate description of light few-electron systems relies on nonrelativistic version of QED, called NRQED theory. Relativistic, retardation, electron self-interaction, and vacuum polarization effects can all be accounted for perturbatively by expansion of energy levels in powers of the fine structure constant \( \alpha \),

\[
E(\alpha) = m \alpha^2 \mathcal{E}^{(2)} + m \alpha^4 \mathcal{E}^{(4)} + m \alpha^5 \mathcal{E}^{(5)} + m \alpha^6 \mathcal{E}^{(6)} + \ldots
\]

(1)

where expansion coefficients \( \mathcal{E}^{(i)} \) may include powers of \( \ln \alpha \). Since these expansion coefficients are expressed in terms of the first- and second-order matrix elements of some operators with the nonrelativistic wave function, the accuracy of the numerical calculation strongly depends on the quality of this function. For example, MCHF calculations \([7–9]\) are accurate only to three digits because the wave function is a combination of Slater determinants and does not satisfy the cusp condition. A much more accurate nonrelativistic wave function can be obtained by using an explicitly correlated basis set such as Hylleraas functions \([10–13]\). However, three-electron integrals with explicitly correlated functions are much more complicated than two-electron ones. Moreover, the required number of basis functions has to be much larger in order to achieve similar accuracy as for two-electron systems. So the extension of QED calculations to a three-electron system is not a simple task. In our recent works \([6, 14]\) we performed complete calculations of higher-order \( m \alpha^6 \) and \( m \alpha^7 \ln \alpha \) corrections to Li and Be\(^+\) \( 2P_{3/2} - 2P_{1/2} \) fine splitting. Here we aim to present in more detail the computational methods.

The fine structure splitting at the leading order \( E^{(4)}_{\text{fs}} \) is given by the expectation value

\[
E^{(4)}_{\text{fs}} = \langle H^{(4)}_{\text{fs}} \rangle
\]

(2)

of spin-dependent operators from the Breit-Pauli Hamiltonian \([15]\).

\[
H^{(4)}_{\text{fs}} = \sum_a \frac{Z \alpha}{4 m^2 r_a^3} \vec{\sigma}_a \left[ (g - 1) \vec{r}_a \times \vec{p}_a \right] + \sum_{a \neq b} \frac{\alpha}{4 m^2 r_{ab}^3} \vec{\sigma}_a \left[ g \vec{r}_{ab} \times \vec{p}_b - (g - 1) \vec{r}_{ab} \times \vec{p}_a \right],
\]

(3)

where \( g \) is the exact electron g-factor. The mean value in Eq. (2), \( \langle \ldots \rangle \equiv \langle \Phi | \ldots | \Phi \rangle \) is calculated using the wave function \( \Phi \) from the stationary Schrödinger equation

\[
(H - E) \Phi = 0
\]

(4)

with the nonrelativistic Hamiltonian \( H \) in the infinite nuclear mass limit

\[
H = \sum_a \frac{\vec{p}_a^2}{2 m} + V
\]

(5)

\[
V = \sum_a -\frac{Z \alpha}{r_a} + \sum_{a > b} \frac{\alpha}{r_{ab}}
\]

(6)

The Li and Be\(^+\) fine structure in the leading order, including finite nuclear mass corrections, has been calculated by using the Hylleraas functions in Refs. \([10, 13]\). The high accuracy is achieved by the use of a relatively large number (about 14 000) of these functions. All matrix elements are expressed in terms of standard and extended Hylleraas integrals, which are obtained with the help of recursion relations \([16, 17]\).

The situation is different with matrix elements of \( m \alpha^6 \) and higher-order operators in the Hylleraas basis, where additional classes of complicated integrals appear, for which no efficient numerical algorithms are known. Other difficulties arise in the evaluation of the second-order matrix element with nearly singular operators. The Green function, or equivalently the sum over pseudo-states, requires large values of nonlinear parameters. This causes severe problems with the numerical stability of recursive algorithms with Hylleraas integrals. We overcome this problem by the application of another basis set, which consists of the explicitly correlated Gaussian functions. We have found \([13, 19]\) that the second-order matrix elements can be calculated with high precision when nonlinear parameters are globally optimized and a large number of Gaussian functions is employed.

II. HIGHER-ORDER FINE STRUCTURE

The \( m \alpha^6 \) correction \( E^{(6)}_{\text{fs}} \) to the fine structure can be expressed as the sum of the first- and second-order matrix ele-
ments with the nonrelativistic wave function,

\[
E^{(6)}_{\text{fs}} = \left\langle H^{(4)} \frac{1}{(E - H)} H^{(4)} \right\rangle + \left\langle H^{(6)}_{\text{fs}} \right\rangle,
\]

where the Breit-Pauli Hamiltonian \( H^{(4)} \) is of the form \[15\]

\[
H^{(4)} = H^{(4)}_A + H^{(4)}_B + H^{(4)}_C
\]

\[
H^{(4)}_A = \sum \left\{ \frac{p^4}{8} + \frac{\pi Z}{8} \delta^3 (r_a) \right\}
\]

\[
+ \sum_{a < b} \left\{ \pi \delta^3 (r_{ab}) - \frac{1}{2} \frac{p_a^i}{r_{ab}} (\delta^{ij} \frac{r_{ab}^i}{r_{ab}^j} + r_{ab}^i r_{ab}^j) r_{ab}^j \right\}.
\]

\[
H^{(4)}_B = \sum \frac{Z}{4 r_a^3} \sigma_a \cdot \vec{r}_a \times \vec{p}_a
\]

\[
+ \sum \frac{1}{4 r_{ab}^3} \vec{r}_{ab} \cdot (2 \vec{r}_{ab} - \vec{p}_a - \vec{p}_b).
\]

\[
H^{(4)}_C = \sum_{a < b} \sigma_i^a \sigma_j^b \delta_{ij} \frac{3 r_{ab}^i r_{ab}^j}{4 r_{ab}^3}.
\]

The potentially singular second-order quadratic term with \( H^{(4)}_A \) in Eq. (7) does not contribute to fine splitting, and thus is excluded from further consideration. \( H^{(6)}_{\text{fs}} \) is an effective Hamiltonian of order \( m \alpha^6 \). Following the derivation in Refs. \[20\] and \[13\], \( H^{(6)}_{\text{fs}} \) can be represented in the following form

\[
H^{(6)}_{\text{fs}} = \sum_{i=1,7} \delta H_i,
\]

and \( A_{i}^a \) is the vector potential at the position of particle \( a \), which is produced by all other particles

\[
e A_a^i = \sum_{b \neq a} \frac{\alpha}{2 r_{ab}} \left( \delta^{ij} \frac{r_{ab}^i}{r_{ab}^j} + \frac{\alpha}{m} \frac{\sigma_b \times \vec{r}_{ab}}{r_{ab}^i} \right).
\]

In order to further improve theoretical predictions, the higher-order \( m \alpha^7 \) contribution is not neglected but instead is approximated by the numerically dominating logarithmic part. It is obtained from the analogous correction to the helium fine structure \[21\] by dropping the \( \sigma^i \sigma^j \) terms because they do not contribute for states with the total electron spin \( S = 1/2 \),

\[
E^{(7)}_{\text{fs,log}} = \left\langle H^{(7)}_{\text{fs,log}} \right\rangle + 2 \left\langle H^{(4)}_B \right\rangle \frac{1}{(E_0 - H_0)} H^{(5)}_{\text{log}}
\]

\[
H^{(5)}_{\text{fs,log}} = \alpha^2 \ln [(Z \alpha)^-2] \left[ \frac{4Z}{3} \sum_a \delta^3 (r_a) - \frac{7}{3} \sum_{b < a} \delta^3 (r_{ab}) \right]
\]

\[
E^{(7)}_{\text{fs,log}} = \alpha^2 \ln [(Z \alpha)^-2] \left[ \frac{Z}{3} \sum_a i \vec{p}_a \times \delta^3 (r_a) \vec{p}_a \cdot \vec{\sigma}_a
\]

\[
- \frac{3}{4} \sum_{b \neq a} i \vec{p}_a \times \delta^3 (r_{ab}) \vec{p}_a \cdot \vec{\sigma}_a \right].
\]

The neglected higher-order corrections are the nonlogarithmic \( m \alpha^7 \) term and the finite nuclear mass corrections to the \( m \alpha^6 \) contribution. They will limit the accuracy of our theoretical predictions for Li and Be$^+$ fine structure.

III. TRANSFORMATION OF MATRIX ELEMENTS

The expectation value of \( H^{(6)}_{\text{fs}} \) in Eq. (12) is transformed initially to a form convenient for numerical calculations with \( ^{2}P \)-states

\[
\delta H_1 = \frac{3}{16} \left( -Z Q_1 + Q_2 \right)
\]

\[
\delta H_2 = -\frac{\pi}{8} D_2
\]

\[
\delta H_4 = -\frac{1}{4} (Q_3 + Q_4)
\]

\[
\delta H_5 = \frac{1}{4} \left[ -Z(Q_5 + Q_6) + Q_7 + Q_8 \right] + \frac{1}{8} \left( -Z P_1 + P_2 \right)
\]

\[
+ \frac{1}{8} (Q_9 - Q_{10} - Q_3 - \frac{1}{16} P_3)
\]

\[
\delta H_6 = -\frac{1}{4} (Q_{11} + Q_{12}) + \frac{1}{16} P_4
\]

\[
\delta H_7 = \frac{Z}{4} (Q_{14} - Q_{15}) - \frac{1}{4} (Q_{17} + Q_{18})
\]

\[
+ \frac{1}{4} (-Q_4 + Q_{19} - Q_{20})
\]

where \( Q_i \) and \( P_i \) are defined in Table I. Additionally, operators \( Q_1, Q_2, \) and \( Q_4 \) are transformed into the sum of the singular D-term with the Dirac-\( \delta \) operator and the regular R-part.
Matrix elements with D-terms are calculated with Hylleraas, while Gaussian functions are used for R-terms, which ensures high numerical precision.

The second-order contribution is split into parts coming from intermediate states with specified angular momentum and spin,

\[
\left\langle H^{(4)} \frac{1}{(E - H)^r} H^{(4)} \right\rangle = \left\langle H^{(4)} \frac{1}{(E - H)^r} \right\rangle_{X_{2S_o} + X_{4S_o} + X_{2P} + X_{4P} + X_{2D_o} + X_{4D_o} + X_{4F}} = \]

where \(1_{2.4X}\) is a projection into doublet or quartet state \(X\), respectively. These contributions are also defined in Table \text{III}.

Most of them can be calculated as they stand. Only the non-symmetric \(\left\langle H^{(4)} / (E - H)^r \right\rangle H^{(4)}\) matrix element needs numerical regularization due to the high singularity of \(H^{(4)}\).

This is done as follows: \(H^{(4)}_A\) is transformed to the regular form by the following transformations

\[
4\pi \delta^3(r_a) = 4\pi \left[ \delta^3(r_a) \right]_r - \left\{ \frac{2}{r_a}, E - H \right\} \]

(31)

\[
4\pi \left[ \delta^3(r_a) \right]_r = \frac{4}{r_a}(E - V) - 2 \sum_b \vec{p}_b \frac{1}{r_a} \vec{p}_b \]

(32)

\[
4\pi \delta^3(r_{ab}) = 4\pi \left[ \delta^3(r_{ab}) \right]_r - \left\{ \frac{1}{r_{ab}}, E - H \right\} \]

(33)

\[
4\pi \left[ \delta^3(r_{ab}) \right]_r = \frac{2}{r_{ab}}(E - V) - \sum_c \vec{p}_c \frac{1}{r_{ab}} \vec{p}_c \]

(34)

\[
\sum_a p^4_a = \sum_a [p^4_a]_r + 4 \left\{ V, E - H \right\} \]

(35)

\[
\sum_a [p^4_a]_r = \frac{4}{E - V^2} - 2 \sum_{a<b} \vec{p}^2_a \vec{p}^2_b \]

(36)

The overall regularized form of \(H^{(4)}_A\) is

\[
H^{(4)}_A = \left[ H^{(4)}_A \right]_r + \{ Q_A, E - H \} \]

(37)

where

\[
Q_A = \frac{Z}{4} \sum_a \frac{1}{r_a} - \frac{1}{2} \sum_{a<b} \frac{1}{r_{ab}} . \]

(38)

The expectation value of the regularized operator is the same as that without regularization. What has changed is the second-order matrix element

\[
\left\langle H^{(4)}_B \frac{1}{(E - H)^r} H^{(4)}_A \right\rangle = \left\langle H^{(4)}_B \frac{1}{(E - H)^r} \right\rangle_{[H^{(4)}_A]_r} + \frac{\delta X_{2P}}{2} \]

(39)

where

\[
\delta X_{2P} = 2 \left( \left\langle H^{(4)}_B Q_A \right\rangle - \left\langle H^{(4)}_B \right\rangle \langle Q_A \rangle \right) \]

(40)

\[
= \frac{Z}{8} \left( Z \langle Q_{21} \rangle + 2 \langle Q_{23} \rangle - \langle Q_{22} \rangle \right) - \frac{1}{4} \left( Z \langle Q_{24} \rangle + 2 \langle Q_{26} \rangle - \langle Q_{25} \rangle \right) - \left( \frac{Z}{4} \langle Q_{29} \rangle + \frac{1}{2} \langle Q_{31} \rangle - \frac{1}{4} \langle Q_{30} \rangle \right) - \left( \frac{Z}{2} \langle Q_{27} \rangle - \langle Q_{28} \rangle \right) \]

(41)

These additional \(Q_i\) operators together with their expectation value are presented in Table \text{III}.

The last considered term, the \(m\alpha^7\ln\alpha\) correction from Eq. (21), is represented as

\[
E^{(7)}_{\text{log}} = \ln((Z \alpha)^{-2}) \left[ \frac{Z}{3} \langle D_1 \rangle - \frac{3}{4} \langle D_2 \rangle + 2 \left( \frac{4Z}{3} Y_1 - \frac{7}{3} Y_2 \right) \right] \]

(42)

where \(D_i\) are defined in Table \text{I} and \(Y_i\) in Table \text{II}. The second-order matrix element \(Y\) requires numerical regularization, similarly to the one in Eq. (39), and is transformed into the following form

\[
Y_1 = \left\langle H^{(4)}_B \frac{1}{(E - H)^r} \sum_a \left[ \delta^3(r_a) \right]_{r} \right\rangle + \delta Y_1 \]

(43)

\[
Y_2 = \left\langle H^{(4)}_B \frac{1}{(E - H)^r} \sum_{b<a} \left[ \delta^3(r_{ab}) \right]_{r} \right\rangle + \delta Y_2 \]

(44)

where

\[
\delta Y_1 = -\frac{1}{2\pi} \sum_a \left( \left. \left[ \frac{1}{r_a} H^{(4)}_B \right] - \left( H^{(4)}_B \right) \left( \frac{1}{r_a} \right) \right\rangle \right) \]

(45)

\[
= \frac{1}{8\pi} \left( -Z \langle Q_{21} \rangle + \langle Q_{22} \rangle - 2 \langle Q_{23} \rangle + \langle Q_{27} \rangle \left( Z \langle Q_{29} \rangle - \langle Q_{30} \rangle + 2 \langle Q_{31} \rangle \right) \right) \]

(46)

are expressed in terms of \(Q_i\) from Table \text{III}.

**IV. SPIN REDUCTION OF MATRIX ELEMENTS**

The wave function \(\Phi^i\) of the \(^2P\) state in a three-electron system is of the form

\[
\Phi^i = \frac{1}{\sqrt{6}} A \left[ \phi^i(\vec{r}_1, \vec{r}_2, \vec{r}_3) \left[ \alpha(1) \beta(2) - \beta(1) \alpha(2) \right] \alpha(3) \right] , \]

(47)
TABLE I: Expectation values of operators for Li and Be$^+ 2^2P_J$ states, $\langle Q \rangle = K_J V$ with the additional prefactor $K_J = \{1, -1/2\}$ for $J = 1/2, 3/2$, correspondingly. All digits are significant.

where $\mathcal{A}$ denotes antisymmetrization and $\phi'(r_1, r_2, r_3)$ is a spatial function with Cartesian index $i$ that comes from any of the electron coordinates. The normalization we assume is

$$\sum_i \langle \Phi' | \Phi \rangle = \sum_i \langle \phi'(r_1, r_2, r_3) | \mathcal{P} | c_{123} \phi'(r_1, r_2, r_3) \rangle = 1$$

(47)

where $\mathcal{P}$ denotes the sum of all permutations of 1, 2, and 3. The $2^2P_{1/2}$ and $2^2P_{3/2}$ wave functions are constructed using Clebsch-Gordon coefficients. Expectation values with these wave functions can be reduced to spatial expectation values with algebraic prefactor $K_J$ for $J = 1/2, 3/2$. Namely, the first-order matrix elements with auxiliary notation $\{K_{1/2}, K_{3/2}\}$ take the form

$$\langle \Phi' | O | \Phi \rangle = \{1, 1\} \langle \phi'(r_1, r_2, r_3) | Q | \mathcal{P} | c_{123} \phi'(r_1, r_2, r_3) \rangle$$

(48)

$$\langle \Phi' \sum a \sigma_a \cdot \mathcal{Q}_a | \Phi \rangle = \{1, -1/2\} i e^{ijk} \sum_a \langle \phi'(r_1, r_2, r_3) | Q_a j | \mathcal{P} | c_{123} \phi'(r_1, r_2, r_3) \rangle$$

(49)

$$\langle \Phi' \sum a \neq b \sigma_a \cdot \sigma_b \cdot \mathcal{Q}_{ab} | \Phi \rangle = \{1, -1/2\} (-2 e^{ijk}) \sum_{ab=12,23,31} \langle \phi'(r_1, r_2, r_3) | Q_{ab} j | \mathcal{P} | c_{123} \phi'(r_1, r_2, r_3) \rangle$$

(50)

where $c_{a,b,m}$ coefficients are defined in Table IV.

The spin reduction of the second-order matrix elements is more complicated. We shall first introduce the following auxi-
TABLE II: Second-order contributions to Li and Be⁺ fine splitting \( X = (K_{3/2} - K_{1/2}) V \), the additional prefactor \( \{K_{1/2} K_{3/2}\} \) is for \( J = 1/2, 3/2 \), correspondingly. The numerical uncertainties are about \( 10^{-4} \)

\]
These formulas, including $K_f$ coefficients, have been obtained with a computer symbolic program.

V. NUMERICAL CALCULATIONS

The spatial function $\phi$ in Eq. (46) is represented as a linear combination of the Hylleraas [23] or the explicitly correlated Gaussians functions [24]

$$\phi = \begin{cases} e^{-a_1 r_1^2 - a_2 r_2^2 - a_3 r_3^2 - a_{12} r_{12}^2 - a_{13} r_{13}^2 - a_{23} r_{23}^2} \\ e^{-a_1 r_1^2 - a_2 r_2^2 - a_3 r_3^2 - a_{12} r_{12}^2 - a_{13} r_{13}^2 - a_{23} r_{23}^2} \end{cases}$$

In the Hylleraas basis we use six sectors with different values of nonlinear parameters $\Omega$, and a maximum value of $\Omega = n_1 + n_2 + n_3 + n_4 + n_5 + n_6 = 12$; details are presented in Refs. [10, 13]. In Gaussian basis we use $N = 256, 512, 1024,$ and 2048 functions with well-optimized nonlinear parameters for each basis function separately. The accuracy achieved for nonrelativistic energies is about $10^{-13}$ in Hylleraas and $10^{-11}$ in Gaussian bases.

These nonrelativistic wave functions are used in evaluation of matrix elements. Most of the $Q$ and $P$ operators in Tables I and III are intractable with present algorithms with Hylleraas functions due to difficulties with integrals with inverse powers of electron distances, but also due to very lengthy expressions in terms of Hylleraas integrals. Thus, we calculate them using Gaussian functions; however, with some exceptions. There are operators $Q_1$, $Q_2$, and $Q_4$, the expectation value of which is very slowly convergent. Namely, the accuracy achieved is as low as $10^{-2} - 10^{-3}$ with as many as 2048 well-optimized Gaussian functions. So, to avoid loss of numerical accuracy, we represent these operators as the sum of the singular $D$-part and the regular $R$-part. The singular $D$-part, numerically dominating, is calculated with Hylleraas functions, while the regular $R$-part, free of singularities, is calculated with a Gaussian basis. This leads to significant improvements in accuracy, so the numerical uncertainties do not affect theoretical predictions for the fine structure. Numerical results for all first-order matrix elements obtained with the largest basis are presented in Table I and III. The achieved precision is at least $10^{-5}$, which is one digit better in comparison to second-order matrix elements described in the following.

The evaluation of second-order matrix elements is much more computationally demanding. First of all, they are obtained only in the Gaussian basis, due to its high flexibility. The resolvent $1/(E - H)$ for each angular momentum is represented in terms of functions with the appropriate Cartesian prefactor, as follows

$$\phi_{S_n} = \epsilon_{ijk} r_a^i r_b^j r_c^k \phi$$

$$\phi_{P_a} = r_a^i \phi$$

$$\phi_{D_n}^{ij} = \left[ \frac{\epsilon_{ikl}}{2} r_c^j + \frac{\epsilon_{jkl}}{2} r_c^i - \frac{\delta_{ij}}{3} \epsilon_{mkl} r_c^m \right] r_a^k r_b^l \phi$$

where subscripts $a$, $b$, and $c$ refer to any of the electrons including the same one. Nonlinear parameters for intermediate states are extensively optimized for each second-order symmetric matrix element. Moreover, one takes all possible representations of angular factors for intermediate states in appropriate proportions to ensure the completeness of the basis. Most importantly, the number of Gaussian functions for intermediate states is chosen to be sufficiently high to saturate the matrix element. Namely, for a given size $N$ of the external wave function, we use $3/2$ $N$ elements for all $D_{n^*}$- and quartet $F_{o^*}$-states, $N$ elements for quartet $P_{o^*}$-states, and $1/2$ $N$ for $S_{o^*}$-states. Among all matrix elements, the most demanding in terms of optimization was that with intermediate states of symmetry $2P_{o^*}$, as the external wave function. Here, the basis set for the resolvent is divided into two sectors. The first sector is built of the known basis functions with the nonlinear parameters determined in the minimization of $E(2P_{o^*})$. For this purpose we took one of the previously generated basis sets of $\Psi$ of size equal to $N/2$. The nonlinear parameters of
this basis remain fixed during the optimization in order to
ensure the accurate representation of the states orthogonal to Ψ.
The second sector, of size equal to 3/2N or N for the matrix
element involving $H_B$ or $[H_A]_{ii}$, respectively, consists of basis
functions that undergo optimization. For the asymmetric ma-
trix elements the basis is combined from two corresponding
symmetric ones.

The most computationally demanding matrix element was
the $\langle [H_A]_{ii}, 1/(E - H') H_B \rangle$ term, and it has the slowest nu-
merical convergence in the Gaussian basis. Numerical results
for matrix elements are summarized in Table II. The achieved
precision is about $10^{-4}$, one digit less than the first-order ma-
trix elements. In addition, we observe significant cancella-
tions between $S = 1/2$ and $S = 3/2$ intermediate states,
and between the first- and second-order terms, see Table V.
The final numerical result for the $m \alpha^6$ contribution in Table
V is relatively quite small. Regarding the $m \alpha^7$ contribution,
the second-order term $Y$ is numerically dominant, and con-
tributions from $D_i$ terms are an order of magnitude smaller.
Altogether this correction is only three times smaller than the $m \alpha^6$ contribution, which is certainly not negligible.

VI. SUMMARY

We have performed accurate calculations of the fine structure
in Li and Be$^+$ using the nonrelativistic QED approach combined
with explicitly correlated basis functions. Relativistic
and QED corrections are represented in terms of matrix elements of effective operators, which are calculated with a
highly accurate nonrelativistic wave function. Numerical re-
sults are summarized in Table VI. We observe an agreement
with the experimental values. However, our result for Li lies
below, while for Be$^+$ above experiments of [5] and [6] re-
spectively. As the sign of all corrections is the same for Li
and Be$^+$, this may suggest that one of these experiments un-
derestimated its uncertainty.

The extension of presented computational approach to other
systems with more electrons is problematic, due to a lack
of formulas for the four-electron Hylleraas integrals. Therefore,
achieving similar accuracy for the four electron systems
would be very challenging.

\end{table}
to one-dimensional representations are

Consider a wave function of three identical particles \(|\vec{r}_1, \vec{r}_2, \vec{r}_3\rangle\). Eigenstates of the nonrelativistic Hamiltonian can be classified by representation of the permutation group \(S_3\). Two of them, \(id\) and \(sgn\), are one dimensional, and the third is two dimensional. The wave functions corresponding to one-dimensional representations are

\[
\psi_S(\vec{r}_1, \vec{r}_2, \vec{r}_3) = \frac{1}{\sqrt{6}} \left[ \phi(\vec{r}_1, \vec{r}_2, \vec{r}_3) + \phi(\vec{r}_1, \vec{r}_3, \vec{r}_2) + \phi(\vec{r}_2, \vec{r}_1, \vec{r}_3) + \phi(\vec{r}_2, \vec{r}_3, \vec{r}_1) + \phi(\vec{r}_3, \vec{r}_1, \vec{r}_2) + \phi(\vec{r}_3, \vec{r}_2, \vec{r}_1) \right]
\]

and

\[
\psi_A(\vec{r}_1, \vec{r}_2, \vec{r}_3) = \frac{1}{\sqrt{6}} \left[ \phi(\vec{r}_1, \vec{r}_2, \vec{r}_3) + \phi(\vec{r}_2, \vec{r}_3, \vec{r}_1) + \phi(\vec{r}_3, \vec{r}_1, \vec{r}_2) - \phi(\vec{r}_2, \vec{r}_1, \vec{r}_3) - \phi(\vec{r}_3, \vec{r}_2, \vec{r}_1) - \phi(\vec{r}_1, \vec{r}_3, \vec{r}_2) \right]
\]

In order to construct the wave functions corresponding to the two-dimensional representation, let us consider the spin-dependent wave function for a three-electron system for the total spin \(S = 1/2\)

\[
\Phi = \frac{1}{\sqrt{6}} A \left[ \phi(\vec{r}_1, \vec{r}_2, \vec{r}_3) [\alpha(1) \beta(2) - \beta(1) \alpha(2)] \alpha(3) \right] + \frac{1}{\sqrt{6}} [\alpha(1) \beta(2) \alpha(3)] \psi_1 + \beta(1) \alpha(2) \alpha(3) \psi_2 + \alpha(1) \alpha(2) \beta(3) \psi_3
\]

where \(A\) denotes antisymmetrization, and

\[
\psi_1 = \phi(\vec{r}_1, \vec{r}_2, \vec{r}_3) - \phi(\vec{r}_2, \vec{r}_3, \vec{r}_1) + \phi(\vec{r}_2, \vec{r}_1, \vec{r}_3) - \phi(\vec{r}_3, \vec{r}_2, \vec{r}_1)
\]

\[
\psi_2 = \phi(\vec{r}_3, \vec{r}_1, \vec{r}_2) - \phi(\vec{r}_1, \vec{r}_3, \vec{r}_2) + \phi(\vec{r}_1, \vec{r}_2, \vec{r}_3) + \phi(\vec{r}_1, \vec{r}_3, \vec{r}_2)
\]

\[
\psi_3 = \phi(\vec{r}_2, \vec{r}_3, \vec{r}_1) - \phi(\vec{r}_3, \vec{r}_1, \vec{r}_2) + \phi(\vec{r}_3, \vec{r}_2, \vec{r}_1) - \phi(\vec{r}_1, \vec{r}_3, \vec{r}_2)
\]

\[
\Phi' = \langle \phi' | \phi \rangle \Phi
\]

and the scalar products between \(\psi_i\) is

\[
\langle \psi_i | \psi_j \rangle = \langle \phi' | \phi \rangle \delta_{ij} (-1 + 3 \delta_{ij})
\]

The two orthogonal and normalized functions can be chosen as \(\psi_1 = \psi_1 / \sqrt{2}\) and \(\psi_{12} = (\psi_2 - \psi_3) / \sqrt{6}\).

The first-order matrix elements of the spin-independent operator \(Q\) are

\[
\langle \Phi | Q | \Phi' \rangle = \frac{1}{6} \langle \psi_1 | Q | \psi_1 \rangle = \langle \phi | Q | \phi \rangle \delta_{ij}
\]
and the second-order matrix elements with $Q_1$ and $Q_2$ are

$$
\langle \Phi | Q_1 \frac{1}{E - H} Q_2 | \Phi \rangle = \frac{1}{6} \langle \psi_i | Q_1 \frac{1}{E - H} Q_2 | \psi_i \rangle
$$

$$
= \langle \phi | Q_1 \frac{1}{E - H} Q_2 | \phi \rangle_S \quad (A11)
$$

In the numerical evaluation of second-order matrix elements with doublet $S = 1/2$ intermediate states, the resolvent $1/(E - H)$ is represented on the basis of functions of proper $S_3$ symmetry, namely $\psi_I$ and $\psi_{II}$

$$
\langle \psi^k_I | E - H | \psi^l_I \rangle = \langle \psi^k_{II} | E - H | \psi^l_{II} \rangle
$$

$$
= \langle \phi^k | E - H | \phi^l \rangle_S = E N_{kl} - H_{kl} \quad (A12)
$$

Hence, the second-order matrix element using Eq. (A7) becomes

$$
\langle \Phi | Q_1 \frac{1}{E - H} Q_2 | \Phi \rangle = \frac{1}{6} \langle \psi_i | Q_1 \psi^k_I \rangle (E N - H)_{kl}^{-1} \langle \psi^l_I | Q_2 | \psi_i \rangle + \frac{1}{6} \langle \psi_i | Q_1 \psi^k_{II} \rangle (E N - H)_{kl}^{-1} \langle \psi^l_{II} | Q_2 | \psi_i \rangle \quad (A13)
$$

$$
= \langle \phi | Q_1 \phi^k \rangle_S (E N - H)_{kl}^{-1} \langle \phi^l | Q_2 | \phi \rangle_S
$$

$$
= \langle P | c_{123} \phi(r_1, r_2, r_3) | Q_1 | \phi^k \rangle (E N - H)_{kl}^{-1} \langle \phi^l | Q_2 | P | c_{123} \phi(r_1, r_2, r_3) \rangle
$$

and the last form is used in the numerical calculations.
