CRISPR/Cas9 technology is a versatile tool for targeted mutagenesis in many organisms, including plants. However, this technique has not been applied to the Japanese morning glory (*Ipomoea [Pharbitis] nil*), a traditional garden plant chosen for the National BioResource Project in Japan. We selected dihydroflavonol-4-reductase-B (DFR-B) of *I. nil*, encoding an anthocyanin biosynthesis enzyme, as the target gene, and changes in the stem colour were observed during the early stages of plant tissue culture by *Rhizobium [Agrobacterium]*-mediated transformation. Twenty-four of the 32 (75%) transgenic plants bore anthocyanin-less white flowers with bi-allelic mutations at the Cas9 cleavage site in DFR-B, exhibiting a single base insertion or deletions of more than two bases. Thus, these results demonstrate that CRISPR/Cas9 technology enables the exploration of gene functions in this model horticultural plant. To our knowledge, this report is the first concerning flower colour changes in higher plants using CRISPR/Cas9 technology.

Methods for targeted mutagenesis have rapidly been developed, and their applications to exotic plants are gradually advancing¹,². Several systems have been developed to induce DNA double-strand breaks (DSBs) at specific genome sites. Such breaks provide increased opportunities to induce site-directed mutations through DNA repair systems, such as non-homologous end joining (NHEJ)³. Among engineered nuclease systems for DSBs, the clustered regularly interspaced short palindromic repeat (CRISPR)-associated endonuclease 9 (Cas9) system can be applied more readily than other systems because of its simple experimental design and high specificity⁴. The CRISPR/Cas9 system has been successfully utilized for targeted mutagenesis in a variety of organisms, including plants, and will increase reverse genetic studies, particularly for plants with good transformation systems and high-quality genome sequences.

The Japanese morning glory, *Ipomoea nil* or *Pharbitis nil*, is one of two traditional horticultural model plants selected for the National BioResource Project in Japan by the Agency for Medical Research and Development (AMED)⁵. A high-quality genome sequence of *I. nil* has recently been reported, with a scaffold N50 of 2.88 Mb, covering 98% of the 750 Mb genome⁶. Because we previously established and improved its transformation methods⁷,⁸, this plant is also a suitable target for the CRISPR/Cas9 system. *I. nil* was imported from China to Japan in the eighth century as a medicinal plant but quickly became a traditional garden plant in Japan. Currently, Asagao

Violet plants exhibited violet-coloured stems; however, more than one-third of the regenerated plants showed as phytohormones\(^1\), gravitropism\(^2\), petal senescence\(^3\), and others. As with transposon mutagenesis\(^4\), \(^5\), and flower shape\(^6\), \(^7\), but also for studies on physiological phenomena, such as the most advanced in the plant kingdom at that time\(^8\), \(^9\). Currently, extensive genetic studies have been conducted on these mutants, and the resulting chromosome map was visually distinguished the bi-allelic mutants during transformation. For the sgRNA sequence, we selected 20 bp in the gene encoding a catalytic site of the DFR enzyme (Fig. 1a)\(^1\). The sgRNA sequence the fourth exon of the gene \([\text{accession number: AB006793}]\) as the target of Cas9 endonuclease. Because null mutations in DFR lead to anthocyanin-less stems, leaves and flowers, we lead to anthocyanin-less stems, leaves and flowers. These observations reconfirm the importance of the protospacer adjacent motif (PAM) in targeted mutagenesis of InDFR-A and InDFR-C causes the null phenotype. Additionally, to confirm the accuracy of the CRISPR/Cas9 system, potential off-target modifications on the two orthologous genes, namely, DFR-A and DFR-C, were examined. These observations reconfirm the importance of the protospacer adjacent motif (PAM) in targeted mutagenesis using the CRISPR/Cas9 system in I. nil. The Cas9 protein is an endonuclease functioning with single guide RNA (sgRNA). The Cas9, sgRNA complex scans double-stranded DNA to detect DNA sequences complementary to the 20-nucleotide (nt) target sequence in the sgRNA and the NGG motif, referred to as the PAM, located imediately after the target sequence. The PAM is essential for the binding of CRISPR/Cas9 to the DNA target\(^1\), \(^2\). The first spontaneous white flower mutant in I. nil was painted in 1631 in Japan, approximately 850 years after the initial import of the blue wild-type flower plants from China. Using the CRISPR/Cas9 system, within a year, we generated several white flower mutants at the same locus but affecting different alleles, indicating the strength of this system and its future prospects. To our knowledge, this study is the first to establish changing flower colour in higher plants using the CRISPR/Cas9 system.

Results

Selection of the target gene and the sgRNA for CRISPR/Cas9. To examine whether the CRISPR/Cas9 system could be applied to I. nil, we selected the InDFR-B gene \([\text{accession number: AB006793}]\) as the target of Cas9 endonuclease. Because null mutations in InDFR-B lead to anthocyanin-less stems, leaves and flowers, we visually distinguished the bi-allelic mutants during transformation. For the sgRNA sequence, we selected 20 bp in the fourth exon of the InDFR-B gene encoding a catalytic site of the DFR enzyme (Fig. 1a)\(^1\). The sgRNA sequence of InDFR-B shows high homology to those of InDFR-A and InDFR-C, with 19/20 and 18/20 matches in the nucleotide sequences, respectively, but only InDFR-B has the PAM next to the sgRNA sequence (Fig. 1a). Potential off-target sites of InDFR-B were searched with GGGenome (http://gggenome.dbcls.jp/) allowing no mismatch in seed sequence which is the most critical determinant of target specificity\(^1\), \(^2\), and 3 bp mismatches in 20 bp sequence. Additional nine sites were derived as potential off-target sites (Supplemental Table S1).

Construct for the CRISPR/Cas9 system and transformation. An Arabidopsis codon-optimized Streptococcus pyogenes Cas9 expression cassette\(^3\), an sgRNA expression cassette, and a selective marker (neomycin phosphotransferase II: NPTII) were combined into a single plant binary vector to form an all-in-one vector for plant transformation (Fig. 1b). Cas9 was driven by the constitutive Ubiquitin4-2 promoter from Petroselinum crispum (pPcUbi)\(^4\), \(^5\). The AiU6 promoter was used to express the sgRNA\(^6\), \(^7\). The construct was introduced to secondary embryos to make stable transgenic I. nil using the Rhizobium (Agrobacterium) method\(^8\), \(^9\). A total of 32 transgenic plants (T1) showing kanamycin resistance with the T-DNA insertion in the genome were obtained.

Identification of the mutants by appearance, CAPS analysis and DNA sequencing. Initially, visual screening based on the appearance of pigmentation with anthocyanin was performed. Non-transgenic cv. Violet plants exhibited violet-coloured stems; however, more than one-third of the regenerated plants showed...
anthocyanin-less stems, typical of the phenotype of null mutations in InDFR-B (Fig. 1c). Notably, we never observed a shift in colouring, namely, violet to green/green to violet within a single plantlet and its stems during growth.

Subsequently, we conducted a cleaved amplified polymorphic sequence (CAPS) analysis to detect mutations in the target region. We designed the expected cleavage site of CRISPR/Cas9 overlapping with the recognition sequence of the restriction enzyme SpeI (Fig. 1a). If the CRISPR/Cas9 cleaved target sequence and NHEJ occurred, then this restriction site would collapse, and the PCR-amplified DNA fragment would not be digested using SpeI. To detect mutations, total DNA was extracted from the transgenic leaves and PCR-amplified, and the resulting PCR products were subjected to SpeI digestion and analysed via agarose gel electrophoresis. The non-mutated PCR fragment of InDFR-B is 537 bp in length, and SpeI digestion produced 303- and 234-bp fragments; however, the mutated PCR fragments were not digested (Fig. 1d). Ten kanamycin-resistant transgenic plants showed SpeI-resistant single DNA bands, indicating that these plants are candidates of the bi-allelic

Figure 1. CRISPR/Cas9-mediated targeted mutagenesis in InDFR-B. (a) Schematic representation of InDFR-A, -B, and -C target sequences. In InDFR-A and -C, the white letters in black highlight indicate mismatches with InDFR-B. In DFR-B, the 20-bp target-specific sequence is shown in blue highlight, and the PAM sequence (TGG) is shown in red highlight. SpeI restriction enzyme sites (ACTAGT) are underlined with green. The green triangles indicate the expected cleavage site of the CRISPR/Cas9 system. (b) T-DNA region of the all-in-one vector, pZD_AtU6gRNA_FFCas9 _NPTII. (c) Kanamycin-resistant regenerated shoots of plants transformed with the CRISPR/Cas9 system. Without targeted mutations, stems were coloured violet (left), whereas bi-allelically mutated stems remained green (right). (d) CAPS analysis of the target region in the InDFR-B locus. Total DNA was extracted from the leaves of transgenic plants and amplified by PCR. The PCR products were digested with the SpeI restriction enzyme, except -RE. M: marker (1,000, 700, 500, 200 and 100 bp); NT-RE: PCR product of a non-transgenic (NT) plant without restriction enzyme digestion. Numerals after # indicate independent T1 plants. N, B, L1, and L2 represent the phenotype of each plant. N: Violet stem and violet flower (same as NT); B: Green stem and white flower; L2: Green stem and violet flower; L1: Violet stem and pale-violet flower. (e) Sequences of targeted mutations in the InDFR-B locus. The NT type sequence is shown at the top and is designated (a). Deleted nucleotides are shown in dashes with black highlight (-). The inserted cytidine residue is shown with black highlight. NT sequences were detected using CAPS analysis (*) in chimaeric plants (#8-1 and 36-2).
mutants. Seventeen plants had both undigested and digested bands (Fig. 1d). Among these mutants, the #36-2 plants showed a shorter DNA fragment approximately 400 bp in length prior to Spel digestion, suggesting a larger deletion in the locus (Fig. 1d). We also analysed the two orthologous loci, namely, InDFR-A and InDFR-C, using CAPS analysis and detected no mutations (Supplemental Fig. S1). Moreover, the DNA sequences of the mutated sites in InDFR-B were determined. The error-free PCR-amplified fragments of the mono-allelic mutants, #8-1 and 36-2, and the bi-allelic mutants, #9-1 and 39-1, were cloned and subjected to DNA sequencing. All plants showed mutations in the predicted cleavage site (Fig. 1e). The detected insertion was one bp, whereas the deletions ranged from two to 98 bp. Interestingly, the L2 chimaeric plant #8-1 showed three patterns of DNA sequences in InDFR-B (two different mutations and one non-mutation), despite the diploid genome. The L1 chimaera plant #36-2 had the longest deletion (98 bp), as predicted in the CAPS analysis (Fig. 1d,e and Supplemental Fig. S2). Moreover, we analysed all the nine off-target candidates sites having a PAM site listed in Supplemental Table S1 with DNA sequencing in the biallelic mutants #9-1 and 39-1, and found there was no mutation in the candidate sites (Supplemental Fig. S6).

Phenotype and genotype of the targeted mutagenesis. Bi-allelic mutants lost anthocyanin, resulting in green stems and white flowers (Fig. 2a). Non-mutated plants showed violet stems and flowers, similar to non-transgenic plants (NT) (Fig. 2b). Most of the mono-allelic mutants also showed violet stems and flowers, similar to non-mutated plants. Notably, plants #8-1 and #36-2, considered mono-allelic mutants based on CAPS analysis, showed green stems with violet flowers and violet stems with pale flowers, respectively (Fig. 2c,d).
These two plants were considered periclinal chimaeras, as these phenotypes were the same as periclinal chimae-
ras resulting from transposon mutagenesis30. In I. nil, the L1 layer is responsible for most of the flower colour,
whereas the L2 layer determines the stem colour and the genotype of gamete cells30. Therefore, plant #8-1 was
considered an L2 chimaeric plant with a targeted mutation in DFR-B in the L2 layer, and plant #36-2 was consid-
ered an L1 chimaeric plant with a targeted mutation in DFR-B in the L1 layer. Because the L2 layer slightly con-
tributed to the petal colour, the flowers of plant #36-2 were pale violet, as previously reported30. Then we checked
the indel mutation and T-DNA existence at the root, stem, leaf and petal of #36-2. The root tissue does not contain
L1 and L2 layers, because L3 forms the central tissues including the pith and roots56. The root of #36-2 had no
mutation and no T-DNA insertion as expected (Supplemental Fig. S5). Therefore, we concluded that plant #36-2
was an L1 periclinal chimaera.

We observed few somaclonal changes in anthocyanin pigmentation during cultivation. Periclinal chimaeric
plants #8-1 and #36-2, considered L2 and L1 chimaeras, respectively, bore sectorial flowers only once during each
life time, baring more than 30 flowers in total (Fig. 3a,b). Sectors of chimaeric plants were extensively studied
using transposon mutants in the DFR-B locus in I. nil30, and two potential causes were considered: somaclonal
mutations and invasion of cells from an adjacent layer. We examined the total DNA extracted from sector cells
using CAPS analysis and confirmed that these white sectors consisted of bi-allelically mutated cells (Fig. 3c).

Inheritance of CRISPR/Cas9 system-induced mutations in subsequent generations. We
observed the progeny (T2) of the transformed plants, and all results were essentially as expected. For example,
the progeny of plant #9-1, bi-allelic mutants, showed green stems (24 plants), indicating that plant #9-1 (T1) was
a perfect bi-allelic-targeted mutant of InDFR-B. Among the offspring of #9-1, targeted mutants without T-DNA
insertions were observed, suggesting that the targeted mutations at InDFR-B and T-DNA were not co-inherited in
#9-1. These plants are targeted mutants and are considered transgenic plants based on process-based definitions
and non-transgenic plants based on product-based definitions38, 39.

We also observed the progeny (T2) of the L2 chimaeric mutant #8-1 and the L1 chimaeric mutant #36-2. The
progeny of plant #8-1 showed green stems (16 plants), and the progeny of plant #36-2 showed violet stems (50
plants). We examined the T-DNA retention of the 24 progenies of the L1 chimaeric mutant #36-2 using PCR
amplification to detect a fragment of the NPTII gene. None of Supplemental Fig. S3 the T2 plants of #36-2 prog-
eny had T-DNA insertions in their genomic DNA (). Because gamete cells originated from L2 cells39, these results
reconfirmed that plant #8-1 was an L2 chimaeric plant and that plant #36-2 was an L1 chimaeric plant.

Figure 3. Phenotypes and genotypes of sectorial chimaeric flowers. (a) A sectorial flower of the L2 chimaeric
plant #8-1. (b) A sectorial flower of the L1 chimaeric plant #36-2. (c) CAPS analysis of the InDFR-B loci in
sectorial chimaeric flowers shown in (a) and (b). Total DNA was extracted from the sectorial white tissues of
the petals indicated by arrows (W) and other coloured tissues of the petal (C), which were subsequently used for
PCR amplification. The PCR products were then digested using the SpeI restriction enzyme (+). -: without SpeI
restriction enzyme digestion; M: marker (1,000, 700, 500, 200 and 100 bp); NT: Total DNA of an NT plant.
Discussion

These data provide the first evidence that the CRISPR/Cas9 system can generate targeted mutagenesis in *I. nil*. Approximately one-third of the stable transgenic plants were bi-allelic mutants at the DFR-B locus in one generation. This high efficiency indicates that the CRISPR/Cas9 system is a highly applicable technique for next-generation breeding in *I. nil* and other horticultural plants.

We successfully visually selected targeted mutagenesis in the early stage during transformation, as the loss of function of the target gene DFR-B prevents the synthesis of stem pigmentation with anthocyanin. In the present study, the gene disruption was detected only at the InDFR-B locus, whereas no mutations were observed in the two orthologous loci, namely InDFR-A and InDFR-C, despite their high homology. These data confirmed the validity of target specificity and the indispensability of PAM for the CRISPR/Cas9 system, avoiding potential off-target mutagenesis. In a recent study, the bi-allelic mutation rate was 31% (10/32), and the total mutation rate was 84% (27/32). The mutation rate of this study was relatively high among higher plants\(^1\). Moreover, a low tendency of obtaining 6% (2/32) chimaeric plants was observed. Because the transformation and regeneration system in *I. nil* uses secondary embryogenesis from secondary embryos induced on immature embryos, we consider that the consequent plant transformant primarily originated from a single cell of the secondary embryo except chimaeric plant #8-1 and #36-2. This unique character of the transformation and regeneration system might affect the low tendency of obtaining chimaeric plants. Because growth rate of secondary embryo had an individual difference slightly, some secondary embryos rarely reached to the regeneration step and could be multi-cell embryo rarely, so the chimaeric mutants were obtained at a low tendency. Despite the high efficiency of obtaining bi-allelic mutations, the overall tendency of the results, 1 bp insertions or short deletions of less than 100 bp, was similar to those in other plants, for example, *Arabidopsis*\(^2\) and *rice*\(^2\). Furthermore, the efficiency of editing depends on sgRNA\(^3\) and the optimization of sgRNA design to maximize activity is advancing\(^4\). By selecting a target sequence with optimization program and software\(^5, 6\), the editing efficiency will increase more in *I. nil*.

In *I. nil*, DFRs are present as a small three-gene family (DFR-A, DFR-B and DFR-C). This gene duplication and evolution is the best example of the escape from adaptive conflict (EAC)\(^6\). In the present study, we successfully inactivated DFR-B without modification in DFR-A and DFR-C genes, although these three genes are tandemly arrayed within a 17-kb DNA region\(^7\). We reconfirmed that DFR-B is the main gene for pigmentation among these three duplicated genes and the EAC in this locus. Using a transposable insertion mutant, a 3′-line of the DFR-B locus and its somaclonal revertants, extensive genetic experiments were conducted in 1930s and 1990s\(^8, 9, 10, 14, 30\). We revisited the same locus in the opposite direction, generating null mutants. This direction, the reverse genetic approach to these legacy phenomena, represents one of the important purposes of targeted mutagenesis.

Plants #8-1 and #36-2, initially classified as mono-allelic mutants as determined by CAPS analysis, showed colour combinations of stems and flowers that differed from those of the other mono-allelic mutants (Fig. 2c,d). Therefore, we considered these plants to be periclinal chimaeric mutants. The shoots of many angiosperms, including *I. nil*, consist of three cell layers: the epidermal cell layer, L1; the sub-epidermal cell layer, L2; and the internal tissues, L3, in the shoot meristems (Fig. 2, below)\(^16, 17\). In wild-type *I. nil*, flower pigmentation occurs mostly in L1 and slightly in L2, whereas stem pigmentation is restricted to L2\(^18\). We concluded that these plants were periclinal chimaeric mutants, initially using the results of the comparison of the phenotype with the literature and later using CAPS analysis (Fig. 1d and Supplemental Fig. S5), sequence determination (Fig. 1e and Supplemental Fig. S2), and observation of inheritance in the T2 generation (Supplemental Fig. S3). These results demonstrated that plant #8-1 was a periclinal chimaera that had bi-allelic mutation in L2, comprised of St #8-1 and St #36-2 was also a periclinal chimaera with a bi-allelic mutation in L1 (Fig. 2c,d). Periclinal chimaeric mutants of DFR-B in *I. nil* were extensively studied by Imai\(^9, 10\) with genetic analyses and reanalysed by Inagaki et al.\(^1\) in molecular and biochemical studies\(^11\). Our plants #8-1 and #36-2 exactly followed their reports, particularly regarding the pale flower colour of the L1 chimaera (Fig. 2d). Moreover, plants #8-1 and #36-2 bore sectorial flowers (Fig. 3). Because these sectorial flowers were rare events and difficult to analyse, we could not decide whether these sectors resulted from somaclonal-targeted mutagenesis or the invasion of the cells in the adjacent layer. However, invasion from neighbouring cell layers to make a sector in a flower has been described for chimaeric mutants by transposons\(^12\), and we did not observe any somaclonal-targeted mutagenesis or secondary mutagenesis, suggesting that sectors in a flower of plants #8-1 and #36-2 are caused by the invasion.

The nucleotide sequencing of the mutated region revealed variable mutations in the InDFR-B region, ranging from one bp insertion to deletions of up to 98 bp (Fig. 1e and Supplemental Fig. S2). In general, random NHEJ occasionally generates mutations without losing gene function, such as in-frame mutations (multiple of 3 nt deletion) or silent mutations (without changes in the amino acid sequence). In the present study, bi-allelic mutations of 3-bp deletions resulted in the leucine 197 deletion, observed in two independent plants (#9-1 and #39-1). The fact that neither mutant could produce anthocyanin suggested that leucine 197 is indispensable for the enzymatic activity of InDFR-B. In the grape DFR\(^4\), crystallization analysis revealed that the conserved proline 190 (corresponding to proline 195 in InDFR-B, next to the deleted leucine 197) is used for the interaction of flavonol with nicotinamide adenine dinucleotide phosphate (NADP\(^+\)) to form the catalytic complex (Supplemental Fig. S4\(^3\)). The deletion of this amino acid leucine 197 might result in the failure of forming stacked saturated nol with nicotinamide adenine dinucleotide phosphate (NADP\(^+\)).
biologically non-transgenic and could not be distinguished from other spontaneous mutants.\(^{38,39}\) We propose that these plants will attract the attention of the public and will improve understanding of NBT.

**Methods**

**Plant materials and growth conditions.** The seeds of *I. nil cv. Violet* (obtained from the NBRP “Morning glory”) were used throughout the experiments. The seedlings were grown on vermiculite fertilized with 1,000-fold diluted Hyponex 6–10–5 solution (Hyponex Japan, Tokyo, Japan) once a week under continuous light (60 mmol m\(^{-2}\) s\(^{-1}\)) at 25°C for two weeks. Those plants were transferred under short-day conditions (8 h light: 16 h dark) at 25°C for two days for flower induction. The plants were then further cultivated under long-day conditions (14 h light: 10 h dark) at 25°C. Immature fruits were collected two to three weeks after flower opening. The immature embryos were isolated from sterilized immature fruits and cultured on an embryo induction medium [MS medium with 3 mg L\(^{-1}\) α-naphthaleneacetic acid (NAA), 6% sucrose and 0.2% Gelrite® (Wako, Tokyo, Japan)] to form the somatic embryos.

**Vector construction and transformation.** An all-in-one binary vector\(^{49}\) harbouring sgRNA, Friedrich Fauser’s Cas9 (FFCas9) and Neomycin phosphotransferase II (NPTII) expression loci was constructed as previously described\(^{50}\). Briefly, two complementary oligo DNAs for the DFR-B target sequence (Forward: 5′-ATTGAAACATGATACCACTACAG-3′; Reverse: 5′-AACACTAGTTGGTAGTATGCTT-3′) were annealed at 95°C for 5 min. The target sequence-cloning vector, pUC19_Au6oligo, was digested with restriction enzyme Bst1 and ligated to the annealed oligo DNA. The cloning vector and binary vector, pZD_Au6gRNA__FFCas9_NPTII, were digested with the restriction enzyme I-SceI, and the sgRNA expression cassettes of each vector were subsequently exchanged.

*Agrobacterium*-mediated transformation using an immature embryo-derived secondary embryo was performed as previously described.\(^{51}\) A complement of oligo DNAs for the DFR-B target sequence (Forward: 5′-TTGCGGGTTACCAAGCTAACGAA-3′; Reverse: 5′-GGCGGTTACCAAGCTAACGAA-3′) were annealed at 95°C for 5 min. The target sequence-cloning vector, pUC19_Au6oligo, was digested with restriction enzyme Bst1 and ligated to the annealed oligo DNA. The cloning vector and binary vector, pZD_Au6gRNA__FFCas9_NPTII, were digested with the restriction enzyme I-SceI, and the sgRNA expression cassettes of each vector were subsequently exchanged.

**Caps analysis.** DNA fragments of InDFRs were PCR-amplified using total DNA of transformants with GoTaq® Green Master Mix (Promega, Madison, WI, USA) and the specific primers (InDFR-A Forward: 5′-TGGCCTACGAGAGACGACAA-3′; InDFR-B Forward: 5′-TGGCCTACGAGAGACGACAA-3′; InDFR-C reverse: 5′-TGGCCTACGAGAGACGACAA-3′; InDFR-D reverse: 5′-TGGCCTACGAGAGACGACAA-3′, inNPTII Reverse: 5′-TGGCCTACGAGAGACGACAA-3′). The thermal cycles for the reaction were same as the NPTII reactions in *InNPTII*, *InDFR-C* and *InPSY*. The PCR cycles for *InDFR-A* were as follows: initial denaturation at 95°C for 2 min followed by 35 cycles at 95°C for 30 s, 50°C for 30 s and 72°C for 1 min and a subsequent extension step at 72°C for 5 min. The amplified DNA fragments were digested with SpeI and analysed via agarose gel electrophoresis.

**Sequencing analysis.** The total DNAs and *InDFR-B* primers were the same as those used in the CAPS analysis. Primer sets for analyzing candidates of off-target mutation were listed in Supplemental Table S2. The PCRs were performed using Advantage® 2 Polymerase Mix (BD Biosciences Clontech, Palo Alto, CA, USA) on a thermocycler, with initial denaturation at 95°C for 2 min followed by 35 cycles at 95°C for 30 s and 68°C for 1 min and a subsequent extension step at 68°C for 1 min. The PCR products were cloned into the pGEM®-T Easy Vector (Promega, Madison, WI, USA) and were sequenced using a CEQ8000 automated DNA sequencer with a DTCS Quick Start Kit (Beckman Coulter, Fullerton, CA, USA). Nucleotide and amino acid sequences were analysed using GENETYX-MAC (Software Kihatsu Co., Tokyo, Japan). The *I. nil* genome sequence was analysed using the NCBI BLAST system 2.2.26 (DNA Data Bank of Japan, Mishima, Shizuoka, Japan)\(^{53}\) to detect potential off-target sequences.

Acknowledgements

We thank Drs H. Puchta, F. Fauser and S. Schiml at the Karlsruhe Institute of Technology for providing the FFCas9 construct used in this study. We are grateful to the National BioResource Project (NBRP) “Morning glory,” which is supported by the Agency for Medical Research and Development (AMED) Japan, for supplying information on the DNA sequence of *I. nil*. This work was partially financially supported by a Cooperative Research Grant of the Plant Transgenic Design Initiative (PTraD), Gene Research Center, the University of Tsukuba, and by the Cabinet Office, Government of Japan, Cross Ministerial Strategic Innovation Promotion Program (SIP). We are grateful to the late Prof. Hiroshi Kamada for advice on genome editing research and express our condolences.

Author Contributions

K.W., S.T. and M.O. designed the study; K.W., A.K., M.E. and K.S.-O. performed the experiments; K.W. drafted the manuscript; and M.O., K.W. and S.T. edited and approved the manuscript.
