In this work, the optimal homotopy asymptotic method (OHAM) has been used to find approximate solutions to the nonlinear fractional-order Kawahara and modified Kawahara equations. The method convergence is controlled by a flexible function known as the auxiliary function. The values of the unknown arbitrary constants in the auxiliary function are computed using the Caputo derivative fractional-order and the well-known approach of least squares. Fractional-order derivatives are taken in the Caputo sense with numerical values in the closed interval \([0, 1]\). The suggested method is directly applied to fractional-order Kawahara and modified Kawahara equations, with no need for small or large parameter assumptions. The numerical results obtained by the proposed method are compared to the new iterative method (NIM). Results reveal that the proposed method converges faster to the exact solution than other methods in the literature.

1. Introduction

Fractional computation was established as an important subject of mathematics in 1695. Fractional calculus ideas have recently been successfully expanded to numerous sectors, and academics have increasingly realized that fractional calculus may well reflect many nonlocal occurrences in the fields of natural science and architecture. Rheology, liquid flow, dispersion diffusion transport, dynamic cycles in self-compatible and porous materials, viscoelasticity, and optics are some of the key areas of fractional calculation today. Very few researchers have drawn on the successful use of fractional systems in these fields to examine their mathematical approximation methods, since diagnostic frameworks are usually difficult to obtain. A variety of real-world problems can be modeled using fractional-order differential equations. These equations have many applications in fluid mechanics, electromagnetic theory, electric grids, diffuse transport, groundwater problems, biological sciences, etc. [1–9]. The exact solution for nonlinear problems is very hard to obtain, and an alternative way is to find the approximate solution. Some familiar approximation methods are used in the series of papers [9–21], etc. Similarly, we extend the well-known optimal homotopy asymptotic method (OHAM) to fractional-order Kawahara and modified Kawahara equations.

The proposed approach was presented by Marinca and Herisanu and applied to resolve nonlinear differential equations in the literature series [22–26]. Recently, Sarwar et al. extended the idea of OHAM fractional-order partial differential equations and used them for different problems having fractional-order derivatives [27, 28]. Nawaz et al. applied the suggested approach to the fractional-order Zakharov-Kuznetsov equations [29]. Likewise, Zada et al.
applied the proposed approach to various fractional PDEs in the series of articles [30, 31]. In this article, the application of OHAM is extended to the modified Kawahara and Kawahara equations together with initial conditions:

\[
\frac{\partial^a Y(\xi, \tau)}{\partial \tau^a} + Y(\xi, \tau) \frac{\partial Y(\xi, \tau)}{\partial \xi} + Y(\xi, \tau) - \frac{\partial^3 Y(\xi, \tau)}{\partial \xi^3} = 0, \quad 0 < \alpha \leq 1,
\]

\[
Y(\xi, 0) = \frac{105}{169} \sec h^4 \left(\frac{\xi}{2\sqrt{13}}\right).
\]  

(1)

\[
\frac{\partial^a Y(\xi, \tau)}{\partial \tau^a} + \frac{\partial Y(\xi, \tau)}{\partial \xi} \left(\frac{\partial Y(\xi, \tau)}{\partial \xi} + \rho \frac{\partial^3 Y(\xi, \tau)}{\partial \xi^3}\right) + \mu \frac{\partial^5 Y(\xi, \tau)}{\partial \xi^5} = 0, \quad 0 < \alpha \leq 1,
\]

\[
Y(\xi, 0) = \frac{3\rho}{\sqrt{-10\mu}} \sec h^2(2k\xi), k = \frac{1}{2} \sqrt{\frac{-\rho}{2\mu}}
\]  

(2)

Here, \(\rho\) and \(\mu\) are constants. Equations (1) and (2) have become the subject of active and wide research topics in recent times [32–34].

2. Preliminaries

Definition 1. The Riemann-Liouville fractional integral operator of an order \(\alpha \geq 0\) of a function \(G \in C^\mu, \mu \geq -1\) is presented by

\[
I_0^\alpha G(\xi) = \frac{1}{\Gamma(\alpha)} \int_0^\xi (\xi - \mu)^{\alpha-1} G(\mu)d\mu, \quad \alpha > 0, \xi > 0,
\]

\[
I_0^0 G(\xi) = G(\xi).
\]  

(3)

Definition 2. The fractional derivative \(G(\xi)\) according to Caputo is presented by

\[
D_a^\alpha G(\xi) = \frac{1}{\Gamma(m-a)} \int_a^\xi (\xi - \mu)^{m-\alpha-1} G^{(m)}(\mu)d\mu,
\]

\[m-1 < \alpha \leq m, \quad m \in N, \quad \xi > 0, \quad G \in C^\mu, \mu \geq -1.
\]  

(4)

Definition 3. If \(m-1 < \alpha \leq m, \quad m \in N, \quad G \in C^\mu, \mu \geq -1\), then \(D_a^\alpha I_0^\beta G(\xi) = G(\xi)\) and \(D_a^\alpha I_0^\beta G(\xi) = G(\xi) - \sum_{k=0}^{\alpha-1} G^{(k)}(\xi - a)/k!\), \(\xi > 0\).

The properties of operator \(I_a^\alpha\) are found in [3, 11]. We introduce the subsequent.

For \(G \in C^\mu, \alpha, \beta > 0, \mu \geq -1, \text{ and } \gamma \geq -1,\)

(1) \(I_0^\alpha G(\xi)\) exist for almost every \(\xi \in [a, b]\)

(2) \(I_0^\alpha I_0^\beta G(\xi) = I_0^\alpha I_0^\beta G(\xi)\)

(3) \(I_0^\alpha I_0^\beta G(\xi) = I_0^\alpha I_0^\beta G(\xi)\)

(4) \(I_0^\alpha (\xi - a)^\gamma = (\Gamma(\gamma + 1)/\Gamma(\alpha + \gamma + 1))(\xi - a)^{\alpha+\gamma}\)

3. OHAM Methodology to Fractional-Order PDEs [27, 28]

To extend the basic theory of OHAM for fractional-order PDEs, we assume that the subsequent general fractional differential system

\[
\frac{\partial^a Y(\xi, \tau)}{\partial \tau^a} = A(Y(\xi, \tau) + F(\xi, \tau)\alpha > 0,
\]

(5)

with initial condition

\[
D_a^\alpha Y(\xi, 0) = g_\alpha(r), \quad (\kappa = 0, 1, 2, \cdots, n-1), \quad D_a^\alpha Y(\xi, 0) = 0, \quad n = [\alpha],
\]

\[
D_a^\alpha Y(\xi, 0) = g_\alpha(r), \quad (\kappa = 0, 1, 2, \cdots, n-1), \quad D_a^\alpha Y(\xi, 0) = 0, \quad n = [\alpha].
\]  

(6)

In the above equation, \(\partial^\alpha/\partial \tau^\alpha\) represents the Caputo fractional derivative operator, \(A\) stands for the differential operator, and \(Y(\xi, \tau)\) represents an unknown function. \(F(\xi, \tau)\) is a function that serves as an analytical function.

The homotopy using OHAM for equation (5) is \(\phi(\xi, \tau; p)\): \(\Omega \times [0, 1] \longrightarrow R\) which is satisfied:

\[
(1 - p) \left(\frac{\partial^\alpha \phi(\xi, \tau)}{\partial \tau^a} - F(\xi, \tau) \right) - H(\xi, \tau) = \left(\frac{\partial^\alpha \phi(\xi, \tau)}{\partial \tau^a} - (A(\phi(\xi, \tau)) + F(\xi, \tau)) \right) = 0.
\]  

(7)

Hence, \(p \in [0, 1]\) which is an embedding parameter and \(H(\xi, \tau)\) shows the auxiliary function such that

\[
H(\xi, \tau) \neq 0 \text{ for } p \neq 0 \text{ and } H(\xi, 0) = 0.
\]  

(8)

Remark 4. The approximate solution \(\phi(\xi, \tau)\) approaches to the closed solution when the numerical values of \(p\) varies for 0 to 1 in the closed interval \([0, 1]\). The convergence of the OHAM purely depends on the auxiliary function.

The auxiliary function \(H(\xi, p)\) is set out below:

\[
H(\xi, p) = pk_1(\xi, C_1) + p^2k_2(\xi, C_1) + p^3k_3(\xi, C_1) + \cdots + p^mk_m(\xi, C_1).
\]  

(9)

In equation (9), \(C_i, i = 1, 2, \cdots, \) convergence control parameters \(k_i(\xi), i = 1, 2, \cdots, \) is a function of \(\xi\).

By extending \(\phi(\xi, \tau; p, C_i)\) in Taylor’s series about \(p\), one can obtain

\[
\phi(\xi, \tau; C_i) = Y_0(\xi, \tau) + \sum_{k=1}^m Y_k(\xi, \tau; C_i)p^k, \quad i = 1, 2, 3, \cdots.
\]  

(10)
Putting $p = 1$, in the above equation, we have

$$Y(\xi, r; C_i) = Y_0(\xi, r) + \sum_{k=1}^{\infty} Y_k(\xi, r; C_i), i = 1, 2, 3, \ldots.$$  

(11)

By substituting equation (10) in equation (7) and equating the coefficient of the same powers of $p$, we acquire the series of problems:

$$p^0 : \frac{\partial^p Y_0(\xi, r)}{\partial r^p} - F = 0,$$

$$p^1 : \frac{\partial^p Y_1(\xi, r; C_i)}{- (1 + C_i) \frac{\partial^p Y_0(\xi, r)}{\partial r^p} + \frac{\partial^p Y_1(\xi, r; C_i)}{\partial r^p} + (1 + C_i) F + C_i A(Y_1(\xi, r; C_i)) = 0},$$

$$p^2 : \frac{\partial^p Y_2(\xi, r; C_i, C_2)}{- (1 + C_i) \frac{\partial^p Y_1(\xi, r; C_i)}{\partial r^p} - C_i A(Y_1(\xi, r; C_i)) - C^2 (F + A(Y_0(\xi, r))) = 0 \ldots}.$$  

(12)

The above problems contain fractional-order derivatives. So, we apply the inverse of the operator $I^p$ on both sides of the above problems:

$$Y_0(\xi, r) = I^p F,$$

$$Y_1(\xi, r; C_i) = I^p \left[ (1 + C_i) \frac{\partial^p Y_0(\xi, r)}{\partial r^p} - (1 + C_i) F + C_i A(Y_0(\xi, r)) \right],$$

$$Y_2(\xi, r; C_i, C_2) = I^p \left[ (1 + C_i) \frac{\partial^p Y_1(\xi, r; C_i)}{\partial r^p} + C_2 (F + A(Y_0(\xi, r))) \right] - C_i A(Y_1(\xi, r; C_i)) \cdots.$$  

(13)

By using these solutions in equation (11), we obtain the approximate solution:

$$\tilde{Y}(\xi, r; C_i) = Y_0(\xi, r) + Y_1(\xi, r; C_i) + Y_2(\xi, r; C_i, C_2) + \cdots.$$  

(14)

The residual $R(\xi, r; C_i)$ is acquired by using equation (14) into equation (5).

$$C_1, C_2, \cdots \text{ can be found by using either the Ritz method, the least squared method, the collocation method, or Galerkin’s method.}$$

The least-square approach is used here. Here, we introduce the functional

$$\chi(C_i) = \int_{\Omega} \int_{0}^{1} R^2(\xi, r; C_i) d\xi dr,$$  

then calculate the optimal values for auxiliary constants $C_i$ by solving the following equation system:

$$\frac{\partial \chi}{\partial C_1} = \frac{\partial \chi}{\partial C_2} = \cdots = \frac{\partial \chi}{\partial C_m} = 0.$$  

(16)

3.1. Convergence Theorem. If the series (11) converge to $Y(\xi, r)$, where $Y_k(\xi, r) \in L(R^r)$ is generated by the zero-order system and the $K$-order deformation, then $Y(\xi, r)$ is the exact solution of (5).

Proof. The following series

$$\sum_{k=1}^{\infty} Y_{i,k}(\xi, r; C_1, C_2, \cdots, C_k)$$  

(17)

converges and is presented by

$$\psi(\xi, r) = \sum_{k=1}^{\infty} Y_{i,k}(\xi, r; C_1, C_2, \cdots, C_k),$$  

(18)

which satisfies the following:

$$\lim_{k \to \infty} Y_{i,k}(\xi, r; C_1, C_2, \cdots, C_k) = 0.$$  

(19)

Indeed, the subsequent equation is fulfilled:

$$Y_{i,1}(\xi, r; C_1) + \sum_{k=1}^{n} Y_{i,k}(\xi, r; C_1, C_2, \cdots, C_k) - \sum_{k=1}^{n} Y_{i,k-1}(\xi, r; C_1, C_2, \cdots, C_k) \cdot (\xi, r; C_{k-1}) = Y_{i,2}(\xi, r; C_2) - Y_{i,1}(\xi, r; C_1) + \cdots + Y_{i,n}(\xi, r; C_n) - Y_{i,n-1}(\xi, r; C_{n-1}) = Y_{i,n}(\xi, r; C_n).$$  

(20)

Now, we have

$$L_{i,1}(Y_{i,1}(\xi, r; C_1)) + \sum_{k=2}^{\infty} L_i(Y_{i,k}(\xi, r; C_{k-1}))$$

$$- \sum_{k=2}^{\infty} L_i(Y_{i,k-1}(\xi, r; C_{k-1})) = L_i(Y_{i,2}(\xi, r; C_2)) + \sum_{k=2}^{\infty} L_i(Y_{i,k}(\xi, r; C_k))$$

$$- \sum_{k=2}^{\infty} L_i(Y_{i,k-1}(\xi, r; C_{k-1})) = 0,$$  

(21)

which satisfies

$$L_{i,1}(Y_{i,1}(\xi, r; C_1)) + L_i(Y_{i,2}(\xi, r; C_2))$$

$$- L_i(Y_{i,1}(\xi, r; C_1)) = \sum_{k=2}^{\infty} L_i(Y_{i,k}(\xi, r; C_k))$$

$$- \sum_{k=2}^{\infty} L_i(Y_{i,k-1}(\xi, r; C_{k-1})) = 0,$$  

(22)

$$+ N_{i,k-m}(Y_{i,k-1}(\xi, r; C_{k-1})) + g_i(\xi, r) = 0.$$

| 0.1   | 0.258678 | 0.256153 | 0.256153 |

Now, if $C_m$, $m = 1, 2, 3, \ldots$, is correctly selected, then the equation leading to

$$L_1(Y_1(\xi, \tau) + A = 0$$

is the exact solution.

4. Main Results

We test our adopted procedure OHAM for finding the approximate solution of the fractional-order Kawahara equation. For most of the computational work, we used MathType and Mathematica 10.

4.1. Numerical Solution of Fractional Kawahara Equation

First, we assume that the time-fractional Kawahara equation is given in [35]:

$$\alpha \frac{\partial^\alpha Y_1(\xi, \tau)}{\partial \tau^\alpha} + Y_1(\xi, \tau) \frac{\partial^\alpha Y_1(\xi, \tau)}{\partial \xi^\alpha} = 0, \quad 0 < \alpha \leq 1.$$  \hspace{1cm} (24)

Subject to I.C.,

$$Y(\xi, 0) = \frac{105}{169} \text{sech}^4 \left( \frac{\xi}{2\sqrt{13}} \right).$$  \hspace{1cm} (25)

For $\alpha = 1$, an exact solution for equation (24) is found by [35] as

$$Y'(\xi, \tau) = \frac{105}{169} \text{sech}^4 \left( \frac{1}{2\sqrt{13}} \left( \xi - \frac{36\tau}{169} \right) \right).$$  \hspace{1cm} (26)

Recall the OHAM preparation given in Section 3, we obtain the subsequent problems:

Zero-order problem:

$$\frac{\partial^\alpha Y_0(\xi, \tau)}{\partial \tau^\alpha} = 0, \quad Y_0(\xi, 0) = \frac{105}{169} \text{sech}^4 \left( \frac{\xi}{2\sqrt{13}} \right).$$  \hspace{1cm} (27)

First-order problem:

$$\frac{\partial^\alpha Y_1(\xi, \tau)}{\partial \tau^\alpha} = \frac{\partial^\alpha Y_0(\xi, \tau)}{\partial \tau^\alpha} + C_1 \frac{\partial^\alpha Y_0(\xi, \tau)}{\partial \xi^\alpha} - C_1 \frac{\partial^\alpha Y_0(\xi, \tau)}{\partial \xi^\alpha} + C_1 \frac{\partial^\alpha \xi_0(\xi, \tau)}{\partial \xi^\alpha} - C_1 \frac{\partial^\alpha \xi_0(\xi, \tau)}{\partial \xi^\alpha}. $$  \hspace{1cm} (28)
Table 5: Comparison of 1st-order OHAM solution with 3rd-order NIM solution for time-fractional modified Kawahara equations for different values of α.

| ξ | τ | Exact solution | OHAM solution | Absolute error NIM for [35] | Absolute error OHAM for α = 1 |

| 0.04 | 0.06 | 9.475172979 × 10^{-4} | 9.474984314 × 10^{-4} | 9.45216 × 10^{-9} | 9.45216 × 10^{-9} |
| 5 | 0.06 | 9.475266744 × 10^{-4} | 9.474984314 × 10^{-4} | 1.88666 × 10^{-8} | 1.88666 × 10^{-8} |
| 5 | 0.08 | 9.475360132 × 10^{-4} | 9.474984314 × 10^{-4} | 2.82432 × 10^{-8} | 2.82432 × 10^{-8} |
| 0.1 | 0.1 | 9.475453144 × 10^{-4} | 9.474984314 × 10^{-4} | 3.75821 × 10^{-8} | 3.75821 × 10^{-8} |

Second-order problem:

\[
\frac{\partial^\alpha Y_2(\xi, \tau)}{\partial \tau^\alpha} = C_2 \frac{\partial^\alpha Y_0(\xi, \tau)}{\partial \tau^\alpha} + C_1 \frac{\partial^\alpha Y_1(\xi, \tau)}{\partial \tau^\alpha} \\
+ C_2 Y_0(\xi, \tau) \frac{\partial Y_0(\xi, \tau)}{\partial \xi} + C_1 Y_0(\xi, \tau) \frac{\partial Y_0(\xi, \tau)}{\partial \xi} \\
+ C_2 \frac{\partial Y_0(\xi, \tau)}{\partial \xi} + C_1 Y_1(\xi, \tau) \frac{\partial^2 Y_0(\xi, \tau)}{\partial \xi^2} \\
+ C_2 \frac{\partial Y_1(\xi, \tau)}{\partial \xi} - C_2 \frac{\partial^3 Y_1(\xi, \tau)}{\partial \xi^3}. \tag{29}
\]

Apply the inverse operator \( \mathcal{I}^\alpha \), the solution of the above problem is given as follows:

\[
Y_0(\xi, \tau) = \frac{105}{169} \operatorname{sech}^3\left(\frac{\xi}{\sqrt[4]{13}}\right),
\]

\[
Y_1(\xi, \tau, C_1) = \frac{-756C_1 \tau^3 \operatorname{sech}^4\left(\xi/\sqrt[4]{13}\right) \tan\left(\xi/\sqrt[4]{13}\right)}{28561 \sqrt[4]{13} \Gamma(1 + \alpha)},
\]

\[
Y_2(\xi, \tau, C_1, C_2) = \frac{1}{62748511 \sqrt[4]{13} \Gamma(1 + \alpha)} \times \left(1890 e^{-\xi/\sqrt[4]{13}} - 169 \sqrt[4]{13} (C_1 + C_2) (1 + e^{\xi/\sqrt[4]{13}}) \right) \\
+ 92^{2-\alpha} C_1 \left(1 - 3 e^{\xi/\sqrt[4]{13}} + e^{2 \xi/\sqrt[4]{13}} \right) \sqrt[4]{13} \Gamma(1 + \alpha) \operatorname{sech}^3\left(\frac{\xi}{\sqrt[4]{13}}\right). \tag{30}
\]

Figure 1: 3D surface obtained by OHAM solution for fractional Kawahara equation at \( \alpha = 0.5 \).

The second-order OHAM solution is presented as follows:

\[
\tilde{Y}(\xi, \tau, C_1) = Y_0(\xi, \tau) + Y_1(\xi, \tau, C_1) + Y_2(\xi, \tau, C_1, C_2). \tag{31}
\]

For \( \alpha = 1 \), second-order OHAM solution for Kawahara equation is
\[ \hat{Y}(\xi, r) = \frac{105 \text{sech}^4 \left( \frac{\xi}{2\sqrt{13}} \right) \left( 371293 + 72\tau (-9C_1^2 r (-4 + 5 \text{sech}^2 \left( \frac{\xi}{2\sqrt{13}} \right) - 169\sqrt{13}(C_1(2 + C_1) + C_2) \tanh \left( \frac{\xi}{2\sqrt{13}} \right) ) \right)}{62748517}, \]  
\] (32)

For \( \alpha = \frac{2}{3} \), second-order OHAM solution for Kawahara equation is

\[ \hat{Y}(\xi, r) = \frac{105 \text{sech}^4 \left( \frac{\xi}{2\sqrt{13}} \right) \left( 371293 + 72\tau^{2/3} (-18C_1^2 r^{2/3} (-4 + 5 \text{sech}^2 \left( \frac{\xi}{2\sqrt{13}} \right) ) \right) I'(7/13) - 169\sqrt{13}(C_1(2 + C_2) \tanh \left( \frac{\xi}{2\sqrt{13}} \right) I'(5/3) \right)}{62748517}, \]  
\] (33)

4.2. Numerical Solution of Fractional Modified Kawahara Equation. Assume the following time-fractional modified Kawahara system presented by

\[
\frac{\partial^\alpha Y(\xi, r)}{\partial^\alpha \tau} + Y^2(\xi, r) \frac{\partial Y(\xi, r)}{\partial \xi} + \rho \frac{\partial^2 Y(\xi, r)}{\partial \xi^2} + q \frac{\partial^3 Y(\xi, r)}{\partial \xi^3} = 0, \quad 0 < \alpha \leq 1,
\]  
\] (34)

with I.C.,

\[ Y(\xi, 0) = \frac{3\rho}{\sqrt{-10\mu}} \text{sech}^2(k(\xi - \psi), \psi = \frac{25\mu - 4\rho^2}{25\mu}. \] (35)

When \( \alpha = 1 \), the exact solution is given by [35] as

\[ Y(\xi, r) = \frac{3\rho}{\sqrt{-10\mu}} \text{sech}^2(k(\xi - \psi), \psi = \frac{25\mu - 4\rho^2}{25\mu}. \] (36)

Following the OHAM procedure, we have the following.

\[ Y_0(\xi, r) = \frac{3\rho}{\sqrt{-10\mu}} \text{sech}^2 \left( \left( \frac{1}{2} \sqrt{\frac{-\rho}{2\mu}} \right) \xi \right), \]  
\[ Y_1(\xi, r, C_1) = \frac{3C_1\rho^{7/2} r^a \text{sech}^5 \left( \sqrt{\rho k/2\sqrt{5}\sqrt{\mu}} \right) \left( -59 \sin \left( \sqrt{\rho k/2\sqrt{5}\sqrt{\mu}} \right) + \sin \left( \sqrt{\rho k/2\sqrt{5}\sqrt{\mu}} \right) \right) \tan \left( \frac{1}{2} \right) \right)}{500 \sqrt{-\rho \mu^{3/2} \sqrt{2\alpha}}}, \]  
\] (37)

The 1st-order OHAM solution is given by the following expression:

\[ \hat{Y}(\xi, r, C_1) = Y_0(\xi, r) + Y_1(\xi, r, C_1). \]  
\] (38)

5. Results and Discussion

We implemented OHAM to provide approximate numerical solutions to fractional and modified Kawahara equations.

Numerical values are tabulated for the auxiliary constants in Tables 1 and 2 for Kawahara and modified Kawahara equations at various values of \( \alpha \). Table 3 gives the estimation of the second-order OHAM solution and the third-order NIM solution for the Kawahara fractional equation. Table 4 compares the absolute errors of the second-order OHAM solution for various \( \alpha \) values. Table 4 presents the values of the first-order OHAM solution and the third-order NIM solution for the various values of \( \alpha \).
compares first-order OHAM solution with third-order NIM solution for time-fractional modified Kawahara equations for different values of $\alpha$.

Figures 1–3 depict the 3D surfaces obtained by second-order OHAM as well as the accurate solutions to fractional
Kawahara equation at $\alpha = 0.5$ and 1. Figure 4 shows the residual for $\alpha = 0.5$, whereas Figure 5 shows the 2D surface of the second-order OHAM solution for various values of $\alpha$. Figures 6–8 show the 3D plots for the first-order OHAM solution and exact solution for the fractional modified Kawahara equation at $\alpha = 0.5$ and 1. Figure 9 depicts a two-dimensional graph of the first-order OHAM solution for different values of $\alpha$. The residual for $\alpha = 0.5$ is shown in Figure 10.

The results obtained by the second-order OHAM solution for the Kawahara fractional equation agree with both the closed and the NIM solution. Similarly, for fractional modified Kawahara equation, the results achieved by the first-order OHAM solutions are exactly the same as for the third-order NIM solutions.

6. Conclusions

We observe that OHAM converges rapidly towards the closed solution with a lower sequence of approximation of fractional orders of the Kawahara equations and modified Kawahara equations based on the calculated results. The results achieved with the proposed approach are highly encouraging compared to the new iterative method (NIM). This proposed approach is capable of providing the greatest accuracy within the lowest approximation sequence. This approach does not require choices between small and large parameter assumptions in problems. The results are analyzed and explained with the help of graphs by considering different values of parameters. Results reveal that as the value of fractional-order derivatives approaches to 1, the approximate solution converges to the exact solution. The convergence of this approach is independent of initial assumptions. The precision of the proposed approach can be improved by assuming high approximations, and therefore, it may be highly attractive for researchers to use our approach to solve fractional-order systems emerging in the science of technology.
