On the rheological properties of multi-walled carbon nano-polyvinylpyrrolidone/silicon-based shear thickening fluid

Abstract: This study examines the rheological properties of shear thickening fluid (STF) enhanced by additives such as multi-walled carbon nanotubes (MWCNTs), polyvinylpyrrolidone (PVP), and nano-silica (SiO$_2$) at different mass fraction ratios. The rheological properties of the liquid (MWCNTs–PVP/SiO$_2$–STF) and the effect of the rheological properties of the STF under different plate spacing of the rheometer were investigated. The optimal mass fraction mixing ratio was also studied. The MWCNTs–PVP/SiO$_2$–STF system with different PVP mass fractions was fabricated using ultrasonic technology and the mechanical stirring method. Then, the steady-state rheological test of the MWCNTs–PVP/SiO$_2$–STF system was carried out with the aid of the rheometer facility. Dynamic rheological and temperature sensitivity tests on the MWCNTs–PVP/SiO$_2$–STF system with 0.1 and 0.15% PVP mass fractions were performed. The rheological test results show that the MWCNTs–PVP/SiO$_2$–STF system has a significant shear thickening effect when the PVP mass fraction is increased from 0 to 0.15%. When the PVP mass fraction is 0.1% and the plate spacing is 1 mm, the system exhibits the best shear thickening performance. This is based on the following facts: the viscosity can be achieved as 216.75 Pa·s; the maximum energy storage and energy consumption capabilities can be observed. As a result, PVP can significantly enhance the shear thickening performance of the MWCNTs/SiO$_2$–STF system.

Keywords: shear thickening fluid, multi-walled carbon nanotubes, polyvinylpyrrolidone, silica, rheological properties

1 Introduction

Shear thickening fluid (STF) [1–4] is a composite material formed by uniformly dispersing micro-nano particles in a dispersion medium. Under normal conditions, it has a certain fluidity, but when external energy forces its shear rate to exceed a certain threshold, the STF viscosity will increase non-linearly and instantaneously and change from a fluid to a hard solid-like state [5–8]. The system has fast response speed, reversible physical form process, and exhibits excellent energy absorption and energy consumption ability. As a result of its remarkable energy absorption, it is widely used in body armor, engineering shock absorption [9–14], and other fields.

At present, some scholars prepare new STF systems by changing the dispersed phase and adding modified additives [15–17] to obtain STF with better rheological properties. Wei et al. [18] prepared the MWCNT/SiO$_2$–STF by using the strong adsorption characteristics of multi-walled carbon nanotubes (MWCNTs) on nano-silica (SiO$_2$). They explored the rheological properties of the new STF. Shang Xu et al. [19] studied the effects of polyvinylpyrrolidone (PVP) of different molecular weights on the rheological properties and stability of MWCNTs. His experiment showed that when the molecular weight of PVP is K30, the degree of adhesion on the surface of MWCNTs is higher, which is conducive to the dispersion of MWCNTs. Liu et al. [20] combined triethoxysilane ((3-aminopropyl)triethoxysilane) modified glass fiber with conventional electrolyte to prepare an impact-resistant electrolyte. The electrolyte maintains good electrochemical stability and shear thickening effect when subjected to the action of a large shearing force. Nakonieczna et al. [21] added MWCNTs to the shear thickening solution of modified polypropylene glycol and amorphous silica. The impact test results show that MWCNTs can effectively enhance the impact resistance of the STF. Fu et al. [22] studied the confined compression behavior of STF by using concentrated submicron particles of styrene. The experimental results show that the
compressibility of STF begins to decrease when the applied compressive stress is greater than 4 MPa.

PVP [23–26] is an amphiphilic polymer with a special structure. It can interact both with water and oils. It has film-forming, cohesive, solubilizing effects, and can be used as a polymer surfactant with superior performance. MWCNT [27–31] is a quantum material whose axial dimension is in the order of microns and the radial dimension is in the order of nanometer. It has extremely high composite material reinforcement performance. The combination of the above two materials can greatly change the surface morphology of the composite material, which is useful to improve the shear thickening performance of the composite material. Hashim et al. [32] found that the existence of the Al₄C₃ phase of the MWCNT/aluminum matrix and the physical conditions of the MWCNT determine the strength of the interface bond. Ijaz Khan et al. [33] studied asymmetrical peristaltic flow conical channels constrained by MWCNTs. Experiments show that the viscosity of nanomaterials depends on the volume fraction and temperature of nanoparticles. Zhuang et al. [34] used nitrogen-doped carbon nanotube carriers to support nickel nanoparticles to make them have the hydrogen oxidizing activity of platinum group metals. Its catalytic performance has been increased by 33 times, and the material has shown great potential in the field of high-performance fuel cell catalysis. Abbasi et al. [35] used TiO₂ nanoparticles of different concentrations to attach MWCNTs to explore its rheological properties. The results show that MWCNT–TiO₂ exhibits shear thickening behavior. Liu et al. [36] used PVP to modify SiO₂ and affected its shear thickening effect by changing the interface effect of nano-SiO₂, providing a new method for optimizing SiO₂-based STF. Sun et al. [37] used energy spectrometer and other methods to microscopically characterize nano-zirconia (ZrO₂), nano-silica (SiO₂), and ZrO₂/SiO₂ powders. And they further explored the rheological properties of ZrO₂/SiO₂–STF. Li et al. [38] used PVP coating to fill and cover the graphene surface in thermoplastic polyurethane (TPU)/graphene nanomaterials. PVP as a dispersant for TPU/reduced graphene oxide composite materials can effectively enhance the material interface interaction, and the modification effect of PVP coating on the TPU/graphene nanomatrix can increase the stress in the low modulus region. Wang et al. [39] studied the use of PVP to modify the surface of ZnO nanoparticles to improve their interface properties. The experimenters used PVP to coat silicon dioxide on the surface of ZnO, and the two were tightly combined through strong hydrogen bonds to form a continuous thin layer. This new material can effectively reduce the photocatalytic activity and improves its material durability.

To summarize, MWCNTs have excellent catalytic adsorption performance, while PVP has great advantages in the surface modification of materials and in improving the interface properties of composite materials. At present, some scholars have discussed the effect of the two materials on the rheological properties of the STF in the experiment. They did not study whether the two can be used in combination to modify the STF to improve its rheological properties. Therefore, this study will explore the rheological properties of the MWCNTs–PVP/SiO₂–STF system. The experiment determines the shear thickening performance of the optimal system under steady-state conditions by testing the MWCNTs–PVP/SiO₂–STF system with different mixing ratios. Then, the optimal plate spacing of the STF is selected based on the steady-state conditions of the obtained optimal system under different plate spacings. Based on the above conclusions, the experimental modulus relationship under dynamic conditions characterizes the rheological properties of the MWCNTs–PVP/SiO₂–STF system under the optimal plate spacing of the rheometer. Finally, the influence of temperature on the rheological properties of the MWCNTs–PVP/SiO₂–STF system was explored.

2 Experimental study

2.1 Materials

Nanosilica powder with an average particle size of 12 nm was purchased from the Chinese Chemical Company Reckitt Benckiser. Polyethylene glycol PEG200 was purchased from Shandong Yousuo Chemical Technology Co., Ltd, China. Its hydroxyl value is 510–623 mg KOH/g, and it is a stable transparent liquid at room temperature. PVP (PVP K30 analytical grade) with a pale yellow powder appearance was purchased from Xilong Science Co., Ltd. MWCNTs with a black powder appearance were purchased from China Hengqiu Nano Reagent Co., Ltd. Its inner diameter is 2–6 nm, outer diameter is 9–18 nm, and length is 3–12 μm.

2.2 STF preparation

Before preparing the MWCNTs–PVP/SiO₂–STF system, put the SiO₂ particles in a vacuum drying oven for 8 h. During the preparation process, the experiment should maintain a constant temperature water bath environment [40].
First, take 200 mL PEG200 and the corresponding mass of MWCNTs powder into the beaker, and mechanically stir until they become uniform. Second, during the stirring process, SiO2 and PVP powders are gradually added according to the requirements of different mixing ratios of the MWNT–PVP/SiO2–STF system. Then use an ultrasonic oscillator to continuously shake the container until the mixed nanoparticles are uniformly dispersed in the PEG200. Finally, put the configured MWCNTs–PVP/SiO2–STF in a vacuum drying oven at 108°C for 24 h. After taking it out, a stable MWCNTs–PVP/SiO2–STF system can be obtained.

2.3 Rheological test

The AR2000 rheometer from the American TA Company (Figure 1) was used to test the steady-state and dynamic flow performance of MWNTs–PVP/SiO2–STF with different mixing ratios. Each sample was randomly selected from five locations in the corresponding beaker for sampling and testing. The diameter of the plate rotor was 30 mm, and the distance between the plates was 1 mm. The specific tests conducted are as follows: (1) under the conditions of a temperature of 25°C and a shear rate sweep range of 0.1–1,000/s, a steady-state rheological test of MWNTs/SiO2–STF with different mixing ratios was performed. (2) Under the fixed angular frequency of 80 rad/s and a strain sweep range of 0.1–2,000%, the optimal mix ratio MWNTs/SiO2–STF was dynamically tested. (3) Under the fixed strain amplitude of 75, 150, 300, and 600% and a frequency sweep range of 0.1–600 rad/s, the optimal mix ratio MWNTs/SiO2–STF was tested dynamically.

2.4 Temperature sensitivity test

The temperature sensitivity test of the MWNTs–PVP/SiO2–STF system with a PVP mass fraction of 0.1% was carried out using the AR2000 rheometer of the American TA Company. The diameter of the test plate rotor was 30 mm, and the plate spacing was 1 mm. The specific test is as follows: under temperatures of 5, 12.5, 25, 40, and 60°C and a shear rate scanning range of 0.1–1,000/s, conduct steady-state rheological tests on the shear thickeners with different mixing ratios.

3 Results and discussion

3.1 Steady-state rheological performance

Figure 2 shows the shear viscosity–shear rate change curve of the MWNTs–PVP/SiO2–STF system with different PVP mass fraction ratios under the shear rate scanning range of 0.1–1,000/s. It can be seen from Figure 2 that when compared with the MWNTs/SiO2–STF system, the MWNTs–PVP/SiO2–STF system has good shear thickening performance. Its viscosity peaks are greatly increased, and the critical shear rate is significantly reduced.

It can also be seen from Figure 2 that with the increase of the PVP mass fraction, the viscosity curve of the system does not show the regularity of consistent changes. Before the mass fraction of PVP reaches 0.15%, the initial viscosity of the system gradually decreases and the peak viscosity gradually increases with the increase of the mass fraction of PVP. The reason is that the MWNTs–PVP/SiO2–STF system has dispersibility and adhesion to MWNTs due to PVP. It coats the surface of MWNTs so that the clustered MWNTs are separated. In addition, the PVP attached to MWNTs can form a new type of MWNTs–PVP particles with a relatively
The structure of the new particle is flocculent. When external factors increase the shear rate of the system, the new MWCNTs–PVP particles with a flocculent structure are more likely to adsorb a large amount of SiO$_2$ particles. Therefore, a new type of “particle clusters” with a larger number, larger volume, and more fullness can be formed, which hinders the flow of the STF system, resulting in a decrease in the initial viscosity of the system and an increase in the peak viscosity. But when the PVP quality score reaches 0.15%, due to the continuous increase of PVP, the PVP has the same interface effect on both the MWCNTs and the SiO$_2$ particles. Therefore, when external factors increase the shear rate of the system, the different molecular groups covering a large amount of PVP repel each other, and the peak viscosity of the system decreases. With the continuous increase in the PVP mass fraction, the critical shear rate of the MWCNTs–PVP/SiO$_2$–STF system decreased first and then increased. It further shows the process of PVP with different mass fractions adhering to the MWCNTs and SiO$_2$ particles. The priority and effect of PVP on the selection of the two different materials of MWCNTs and SiO$_2$ are verified from the side.

Table 1 of this test shows that the MWCNTs–PVP/SiO$_2$–STF system with a PVP mass fraction of 0.15% has the most obvious shear thickening effect. Compared to the STF without PVP, its peak viscosity increased from 118.993 to 299.554 Pa s, an increase of 151.74%. At the same time, its critical shear rate is reduced from 15.85 to 12.59/s, a decrease of 20.57%. The main reason may be that PVP coats the surface of MWCNTs to form an interface layer, which increases the surface area and roughness of MWCNTs. PVP disperses the gathered MWCNTs, so that the MWCNTs/SiO$_2$–STF system forms a large number of “particle clusters” with uniform and stable dispersion of the system. At the same time, a large number of particle clusters can adsorb more SiO$_2$ particles on the rough MWCNTs surface. As the spacing of the particle clusters becomes smaller, it is easier to form an agglomeration effect to enhance the shear thickening performance of the system. Consider the influence of the parameter range of the peak viscosity rate of the rheological properties of the MWCNTs–PVP/SiO$_2$–STF system. The shear thickening performance of the MWCNTs–PVP/SiO$_2$–STF system with a PVP mass fraction of 0.10% is the most significant. The peak viscosity rate parameter range of the system is 25.63–187.20/s. At the same time, compared to the system without PVP, its peak viscosity increased from 118.993 to 216.750 Pa s, an increase of 82.15%. It can meet the requirements of maintaining excellent energy consumption of the STF in a wide range of speeds.

All modified samples showed obvious shear thinning and shear thickening than MWCNT/SiO$_2$–STF. The reason is that PVP has dispersibility for MWCNTs and can increase its surface roughness. This makes the number of this new type of “particle clusters” far greater than the number of agglomerated MWCNTs. When compared with MWCNT/SiO$_2$–STF, the MWCNTs–PVP/SiO$_2$–STF system has more “particle clusters” and smaller average spacing. Therefore, the critical shear rate of the latter is lower and the peak viscosity is larger, which has an obvious shear thickening effect.

The scanning electron microscopic experiment was carried out on the MWCNTs–PVP/SiO$_2$ particles and the MWCNTs/SiO$_2$ particles (Figure 3 shows the mechanism of action and Figure 4 shows the microscopic morphology). Explore the material composite relationship and the dispersion of nanomaterials from a microscopic point of view. Specific performance: On the one hand, compared to the MWCNTs/SiO$_2$ system in the MWCNTs–PVP/SiO$_2$–STF system, the increase in the PVP content at the beginning can effectively disperse the agglomerated MWCNTs and reduce the initial viscosity. On the other hand, the number and unique structure of the “new particle clusters” hinder the flow of the system under external forces and increase the peak viscosity. Therefore, the new system is superior to the shear thickening performance of the MWCNTs/SiO$_2$ system. When the mass fraction of PVP increases to 0.15%,
its peak viscosity significantly increases to 299.554 Pa.s. The reason is that after the PVP content is approximately equal to the “critical content,” a large number of new particle clusters are formed. The new type of particle cluster has a flocculent structure with a rough surface, which can act synergistically with SiO₂. Although the number of particle clusters increases, the average spacing between the particles is reasonable. This makes the initial viscosity low and the peak viscosity high, showing a strong shear thickening effect. This shows that the system has reached the best mix ratio. After further increasing the PVP mass fraction, the initial viscosity of the MWCNTs–PVP/SiO₂–STF system increased sharply and then began to decrease. The reason is that after a large amount of PVP is grafted with MWCNTs, the remaining part of PVP is modified around the SiO₂ particles. This results in the formation of a large number of particle clusters, which leads to a sharp increase in the initial viscosity of the fluid. Due to the continuous addition of PVP, the periphery of the two particle clusters contains PVP particles. This increases the molecular force between the clusters of particles. Therefore, the initial and peak viscosities of the fluid have decreased. This also shows once again that the 0.15% sample system has reached the optimal state. Although continuing to increase the PVP content can increase the initial viscosity, the shear thickening performance of the system weakens as the peak viscosity decreases significantly. Therefore, the content of MWCNTs can be increased according to actual demand to control its rheological properties. It can be seen from Figure 2 that compared to the MWCNTs/SiO₂ system, the critical shear rate and the peak shear rate of the MWCNTs–PVP/SiO₂–STF system have a larger gap, because the structure of the new particle clusters in the MWCNTs–PVP/SiO₂–STF system has a strong adsorption effect on SiO₂. This makes the shear thickening effect more likely to occur under the action of a shear force. Considering the influence of the shear rate range of the system in actual engineering applications, the comprehensive rheological parameters of the 0.1% PVP sample are more in line with the requirements.

As the number of “particle clusters” in the MWCNTs–PVP/SiO₂–STF system increases and the average spacing decreases, the initial test plate spacing may hinder the formation of new “particle clusters.” This may make the outer layer of MWCNTs–PVP particles unable to effectively adsorb SiO₂ particles. As a result, a new type of “particle cluster” of MWCNTs–PVP/SiO₂–STF of suitable size cannot be formed, which weakens the effect of the “particle cluster.” This will affect the accuracy of the experimental results. Therefore, based on the above experimental conclusions, the PVP with the optimal mix ratio was selected for the steady-state rheological tests under different plate spacings.

Figure 5 shows the effect of the rheometer on the steady-state rheological properties of the 0.1% PVP sample under different plate spacing. It can be seen from Figure 5 that the MWCNTs–PVP/SiO₂–STF system has a significant impact on the system under conditions of different plate spacing. Changing the plate spacing can not only significantly reduce the critical shear rate of the system, but also significantly increase the peak apparent viscosity.

From Table 2, it is concluded that the peak viscosity of MWCNTs–PVP/SiO₂–STF with a PVP mass fraction of 0.1% was increased by 17.79, 3.19, 58.37, and 29.07%
compared with the MWNT/SiO$_2$ system under the same inter-plate spacing. When the distance between the plates is doubled and quadrupled from 0.25 mm, the peak viscosity of the system increases and the critical shear rate decreases. The possible reason is that the PVP dispersed and agglomerated MWCNTs resulted in the formation of a larger number of new “particle clusters.” When the spacing between the plates is 0.25–0.5 mm, the plates hinder the formation of new particle clusters. When the plate spacing increases from 0.5 to 1.0 mm, the shear thickening phenomenon is significant. The above phenomenon may be due to the appropriate size and uniform distribution of the new “particle clusters” in the system. It can exhibit good shear thickening under the condition of 0.1 mm plate spacing. When the plate spacing is further increased to 1.5 mm, the increase in the spacing between plates increases the average spacing of the new particle clusters. Therefore, the peak viscosity is reduced.

### 3.2 Dynamic rheological performance

It can be seen from the above research that the steady-state rheology of 0.15% MWCNTs–PVP/SiO$_2$–STF system has a significant shear thickening performance. Therefore, this section mainly studies the dynamic rheological properties of the 0.15% MWCNTs–PVP/SiO$_2$–STF system.

It can be seen from Figure 6 that when the strain amplitude increases from 75 to 600%, the storage modulus of the system first increases and then decreases as the angular frequency increases. The energy dissipation modulus increases with the increase of the angular frequency, and the critical angular frequency decreases with the increase in the strain amplitude. Although the storage modulus decreases significantly with the increase in the strain amplitude when the angular frequency is small, the peak storage modulus is almost unaffected. Compared to the storage modulus, the dissipation modulus exhibits similar behavior. For example, the peak energy

**Figure 6:** The relationship between the storage modulus and frequency of the 0.15% MWCNTs–PVP/SiO$_2$–STF system.

### Table 2: The rheological characteristics of the two systems under different plate spacings

| STF           | Clearance distance (mm) | Critical shear rate (/s) | Critical viscosity (Pa.s) | Peak viscosity (Pa.s) |
|---------------|-------------------------|--------------------------|---------------------------|-----------------------|
| 0.10% MWCNTs–PVP/SiO$_2$–STF | 0.25                     | 39.8195                  | 93.9988                   | 137.274               |
| 0.10% MWCNTs–PVP/SiO$_2$–STF | 0.50                     | 31.6268                  | 83.5023                   | 174.553               |
| 0.10% MWCNTs–PVP/SiO$_2$–STF | 1.00                     | 25.1202                  | 42.7383                   | 216.75                |
| 0.10% MWCNTs–PVP/SiO$_2$–STF | 1.50                     | 25.1202                  | 24.9262                   | 213.937               |
| MWCNTs/SiO$_2$–STF         | 0.25                     | 39.8237                  | 43.699                    | 116.493               |
| MWCNTs/SiO$_2$–STF         | 0.50                     | 15.8514                  | 96.7629                   | 169.163               |
| MWCNTs/SiO$_2$–STF         | 1.00                     | 25.1203                  | 81.0411                   | 136.864               |
| MWCNTs/SiO$_2$–STF         | 1.50                     | 15.8493                  | 65.1486                   | 165.76                |
storage of the 0.15% MWCNTs–PVP/SiO$_2$–STF system increased from 4280.61 to 10949.50 Pa and the peak energy consumption increased from 3199.05 to 12279.10 Pa. The peak energy storage increases by about 255.79%, and the peak energy consumption increases by 383.84%. In addition, a comparison of Figures 6 and 7 shows that the energy dissipation modulus is always above the storage modulus. This shows that the system is based on energy consumption. The energy consumption of the system indicates that the STF has the potential to reduce structural vibration.

It can be seen from Figures 8 and 9 that when the strain amplitude increases continuously, the storage modulus and energy dissipation modulus of 0.15% MWCNTs–PVP/SiO$_2$–STF increase compared to the other two systems. At the same time, its critical strain amplitude becomes smaller, showing a stable shear thickening ability. When the angular frequency is 80 rad/s, the peak energy storage and peak energy consumption of the 0.15% MWCNTs–PVP/SiO$_2$–STF system are 7061.69 and 10827.3 Pa, respectively, and its peak energy consumption is increased by about 53.32%. In addition, its energy consumption curve is always greater than the energy storage curve. It is more obvious in the range of high strain amplitude. This indicates that the 0.15% MWCNTs–PVP/SiO$_2$–STF system not only exhibits good elastic behavior under low stress, but also has significant energy dissipation ability under high stress.

### 3.3 Temperature sensitivity

It can be seen from Section 3.2 that the MWCNTs–PVP/SiO$_2$–STF system has excellent rheological properties. To further explore the practical applicability of the MWCNTs–PVP/SiO$_2$–STF system, in this section, the influence of ambient temperature on the rheological properties of the system is studied in detail. It can be observed from Figures 10 and 11 that both the systems have significant shear thinning and shear thickening at the tested temperatures. On the whole, the apparent viscosity of both increases greatly as the temperature decreases. However, the influence of temperature on the shear thickening behavior is significantly greater than its influence on the shear thinning behavior. For example, when the temperature of the MWCNTs–PVP/SiO$_2$–STF system increases from 12.5 to 40°C, the apparent viscosity corresponding to a shear rate of 0.1/s decreases only by 46.56%. At the same time, the peak
apparent viscosity reduction rate can reach 86.19%. This is because the temperature rise intensifies the Brownian motion of the molecules. The process of forming particle clusters by molecules is more difficult, resulting in a decrease in the viscosity of the system.

It can be seen from Figures 12 and 13 that the shear thickening effect of the MWCNTs–PVP/SiO$_2$–STF system is greatly affected by temperature changes. The shear thickening coefficient (the ratio of the peak viscosity to the critical viscosity) decreases with increasing temperature. For example, when the temperature of the 0.15% MWCNTs–PVP/SiO$_2$–STF system increases from 5 to 12.5, 25, 40, and 60°C, the corresponding shear thickening effects are 31.65, 24.64, 19.77, 11.90, and 2.34, respectively. Its reduction rates are 22.15, 19.76, 39.81, and 80.34%. The reason may be that at higher temperatures, the PVP is not conducive to the combination of MWNT and SiO$_2$ particles. In addition, the hydrogen bonding force is weakened at high temperatures, which is not conducive to the dispersion of particles in polyethylene glycol. Therefore, the shear mechanical properties of the system decrease with the increase in temperature.
4 Conclusion

In this study, MWCNTs–PVP/SiO$_2$–STF systems with different mixing ratios were developed. The shear thickening mechanism of the MWCNTs–PVP/SiO$_2$–STF system was investigated through the rheological performance test. The effect of PVP mass fraction, plate spacing, and temperature on the rheological properties of MWCNTs–PVP/SiO$_2$–STF system was studied. Experiments show that the shear thickening performance of the MWCNTs–PVP/SiO$_2$–STF system has potential research value in the field of engineering vibration reduction and isolation. The main findings can be summarized as:

(1) PVP provides dispersibility and adhesion ability to MWCNTs. It can be compounded to form a new particle cluster structure with a large amount of cotton-like coarse surfaces. The new particle cluster contains SiO$_2$ nano particles which can effectively improve the shear thickening effect of the fluid.

(2) The system tends to be unstable after the PVP content reaches 0.3%. However, excellent shear thickening performance within the range of reasonable mixing ratio can be achieved. When the mass fraction of PVP reaches 0.15% and the distance between the test plates is 1 mm, the shear thickening performance of the MWCNTs–PVP/SiO$_2$–STF system is shown to be most effective. At this configuration, the initial viscosity of the MWCNTs–PVP/SiO$_2$–STF system does not change much, but the peak viscosity is relatively large and the critical shear rate is relatively small.

(3) The dynamic performance test shows that the MWCNTs–PVP/SiO$_2$–STF system has better energy storage and energy consumption capabilities compared to the MWCNT/SiO$_2$–STF system.

(4) The temperature sensitivity test shows that the temperature sensitivity of the MWCNTs–PVP/SiO$_2$–STF system is similar to that of MWCNT/SiO$_2$–STF. Therefore, PVP can significantly improve the shear thickening performance of the system without affecting temperature sensitivity.
