Some mixed ligand complexes of Th(IV) with Mannich base N-(1-morpholinobenzyl)semicarbazide (MBS) and various anions like chloride, nitrate, thiocyanate and perchlorate have been synthesized and characterized. Their probable structures have been elucidated by elemental analysis, determination of molar mass, measurement of molar conductance, spectral and X-ray diffraction studies. The complexes exhibit formulae: [Th(MBS)\textsubscript{3}X], where X = NO\textsubscript{3}–, Cl −, CH\textsubscript{3}COO–, SCN − or ClO\textsubscript{4}–. In all these complexes, N-(1-morpholinobenzyl)semicarbazide acts as a bidentate ligand and anions act as unidentate ligands. The antimicrobial activities of ligand and metal chelates against \textit{E. coli}, \textit{S. aureus}, \textit{K. pneumoniae} and \textit{P. aeruginosa} were also studied.

Keywords: Thorium(IV), Mixed ligand complexes, Morpholinobenzyl semicarbazide.

Introduction

Literature survey reveals that metal chelates of benzaldehyde based Mannich bases have been studied extensively in recent years because of the sensitivity and selectivity of the ligand towards various metal ions [1-5]. The semicarbazide compounds containing amide moiety have a strong ability to form metal chelates. A search through the literature shows that a Mannich base, N-(1-morpholinobenzyl)semicarbazide has been prepared by the condensation of morpholine, semicarbazide and benzaldehyde and its complexes with some transition metals like Cu(II), Ni(II), Co(II) and Zn(II) have been synthesized [6]. In these metal complexes, the ligand is bidentate via the N and O of semicarbazide. The present communication reports the synthesis of some mixed ligand complexes of the Mannich base N-(1-morpholinobenzyl) semicarbazide (Fig. 1) with acetate, chloride, nitrate, perchlorate and thiocyanate of Th(IV). The complexes have been characterized by various physico-chemical techniques like, elemental analysis, magnetic measurements, determination of molar conductivity, spectral and X-ray diffraction studies. The ligand and the metal complexes have biological activities against various microbes like \textit{S. aureus}, \textit{E. coli}, \textit{P. aeruginosa} and \textit{K. pneumoniae}.

Experimental

All the chemicals used were of Merck products. Organic solvents were purified by standard methods. The ligand N-(1-morpholinobenzyl)semicarbazide (MBS) was prepared by reported method [6]. Semicarbazide hydrochloride (1.11 g, 10 mmol) in 20 mL of ethanol was neutralized with ammonia. To this neutralized solution, morpholine (0.9 mL, 10 mmol) was added drop by drop with constant stirring to get a clear solution. To this benzaldehyde (1 mL, 10 mmol) was added drop by drop with constant stirring for about 5 min. The colourless solid formed was filtered and recrystallized from ethanol (yield 81 %, m.p. 217 ºC).

The nitrate and perchlorato complexes were prepared by refluxing an alcoholic solution containing N-(1-morpholinobenzyl)semicarbazide and thorium(IV) salt in the 2:1 ratio for about 3 h. The resulting solution was concentrated to one third of its volume and cooled. The solid thorium complexes formed were filtered, washed with methanol or ethanol and dried \textit{in vacuo}. The preparation of thiocyanato and acetato complexes involved two steps. In the first step, the nitrate complex was prepared. In the second step, the nitrate complex was dissolved in methanol and was mixed with stoichiometric quantity of
aqueous methanolic solution of ammonium thiocyanate (or sodium acetate). The resulting reaction mixture in each case was refluxed for about 3 h to replace the nitrate ions with the thiocyanate or acetate ions. The resulting solution was concentrated to one third of its volume and cooled, the solid complexes formed were filtered, washed with ethanol or methanol and dried in vacuo.

The thorium content of the complexes were determined by oxalate-oxide method [7]. The carbon, hydrogen and nitrogen contents were determined by microanalytical method. The anions present in the complexes were also analyzed wherever possible [8]. The nitrate content of the complex was determined as nitron by using AgNO₃ solution in presence of nitric acid. The perchlorate content was determined as AgSCN [7] from alkali thiocyanate solution by using an ELICO conductivity bridge type CM82T with platinum electrodes (cell constant = 0.94 cm⁻¹). Magnetic susceptibilities were measured at room temperature. The infrared spectra of the ligand and the complexes were recorded on a Perkin-Elmer spectrophotometer and are given in Table-1b.

In the infrared spectrum of MBS, bands appear in the regions 3260 and 1620 cm⁻¹, which are assigned to ν(N-H) and ν(C=O) respectively. The bands due to ν(C=O) and ν(C=N) are located in the regions 1140 and 1670 cm⁻¹, respectively [13,14]. In the spectra of the complexes, the band corresponding to ν(C=O) mode of free ligand, MBS is not observed which indicates the enolization of C=O followed by deprotonation and complexation with metal ions. The ν(C=N) mode of the ligand is shifted to lower frequency regions indicating the complexation of azomethine nitrogen to the central metal ion. The band at 3260 cm⁻¹ due to ν(N-H) of the ligand is absent in the spectra of the complexes, suggesting deprotonation of N-H of the ligand prior to coordination to thorium metal. Based on this, it may be concluded that MBS acts as a monobasic bidentate ligand in the complexes. The additional bands in the spectra of the complexes at 535-475 and 460-415 cm⁻¹ may be assigned to ν(Th-O) of coordinated thiocyanate in the complexes. The infrared spectrum of the nitrate complex of thorium(IV) exhibits three additional bands at 1464, 1340 and 1024 cm⁻¹ which are assigned to ν₂ and ν₁ modes of the coordinated nitrate ions [16-18]. Since the difference between ν₂ and ν₁ is about 124 cm⁻¹, it is suggested that the nitrate ions are coordinated unidirectionally to the thorium(IV) [19].

The thiocyanato complex of thorium(IV) exhibits three additional bands at 2052, 864 and 460 cm⁻¹ which are attributed to ν(C=O) and ν(C=O), respectively. The bands due to ν(C=O) and ν(C=N) are located in the regions 1140 and 1670 cm⁻¹, respectively [13,14]. In the spectra of the complexes, the band corresponding to ν(C=O) mode of free ligand, MBS is not observed which indicates the enolization of C=O followed by deprotonation and complexation with metal ions. The ν(C=N) mode of the ligand is shifted to lower frequency regions indicating the complexation of azomethine nitrogen to the central metal ion. The band at 3260 cm⁻¹ due to ν(N-H) of the ligand is absent in the spectra of the complexes, suggesting deprotonation of N-H of the ligand prior to coordination to thorium metal. Based on this, it may be concluded that MBS acts as a monobasic bidentate ligand in the complexes. The additional bands in the spectra of the complexes at 535-475 and 460-415 cm⁻¹ may be assigned to ν(Th-O) and ν(Th-N) modes, respectively. The dipole moment change in the vibration of Th-O band is larger compared to that in Th-N band. Thus the band due to ν(Th-O) occurs in higher frequency [15] region and is stronger and sharper than ν(Th-N).

The infrared spectrum of the nitrate complex shows three additional bands at 1464, 1340 and 1024 cm⁻¹ which are assigned to ν₂ and ν₁ modes of the coordinated nitrate ions [16-18]. Since the difference between ν₂ and ν₁ is about 124 cm⁻¹, it is suggested that the nitrate ions are coordinated unidirectionally to the thorium(IV) [19].

The thioctanoyl complex of thorium(IV) exhibits three additional bands at 2052, 864 and 460 cm⁻¹ which are attributed to ν(C=O) and ν(C=O), respectively. The bands due to ν(C=O) and ν(C=N) are located in the regions 1140 and 1670 cm⁻¹, respectively [13,14]. In the spectra of the complexes, the band corresponding to ν(C=O) mode of free ligand, MBS is not observed which indicates the enolization of C=O followed by deprotonation and complexation with metal ions. The ν(C=N) mode of the ligand is shifted to lower frequency regions indicating the complexation of azomethine nitrogen to the central metal ion. The band at 3260 cm⁻¹ due to ν(N-H) of the ligand is absent in the spectra of the complexes, suggesting deprotonation of N-H of the ligand prior to coordination to thorium metal. Based on this, it may be concluded that MBS acts as a monobasic bidentate ligand in the complexes. The additional bands in the spectra of the complexes at 535-475 and 460-415 cm⁻¹ may be assigned to ν(Th-O) and ν(Th-N) modes, respectively. The dipole moment change in the vibration of Th-O band is larger compared to that in Th-N band. Thus the band due to ν(Th-O) occurs in higher frequency [15] region and is stronger and sharper than ν(Th-N).

The infrared spectrum of the nitrate complex shows three additional bands at 1464, 1340 and 1024 cm⁻¹ which are assigned to ν₂ and ν₁ modes of the coordinated nitrate ions [16-18]. Since the difference between ν₂ and ν₁ is about 124 cm⁻¹, it is suggested that the nitrate ions are coordinated unidirectionally to the thorium(IV) [19].

The thioctanoyl complex of thorium(IV) exhibits three additional bands at 2052, 864 and 460 cm⁻¹ which are attributed to ν(C=O) and ν(C=O), respectively. The bands due to ν(C=O) and ν(C=N) are located in the regions 1140 and 1670 cm⁻¹, respectively [13,14]. In the spectra of the complexes, the band corresponding to ν(C=O) mode of free ligand, MBS is not observed which indicates the enolization of C=O followed by deprotonation and complexation with metal ions. The ν(C=N) mode of the ligand is shifted to lower frequency regions indicating the complexation of azomethine nitrogen to the central metal ion. The band at 3260 cm⁻¹ due to ν(N-H) of the ligand is absent in the spectra of the complexes, suggesting deprotonation of N-H of the ligand prior to coordination to thorium metal. Based on this, it may be concluded that MBS acts as a monobasic bidentate ligand in the complexes. The additional bands in the spectra of the complexes at 535-475 and 460-415 cm⁻¹ may be assigned to ν(Th-O) and ν(Th-N) modes, respectively. The dipole moment change in the vibration of Th-O band is larger compared to that in Th-N band. Thus the band due to ν(Th-O) occurs in higher frequency [15] region and is stronger and sharper than ν(Th-N).
The metal chelates were tested for their antibacterial activity against *Staphylococcus aureus*, *Klebsiella pneumoniae*, *Escherichia coli* and *Pseudomonas aeruginosa* by well diffusion method [23]. The ligand and the metal chelates were found to be active towards these bacteria. The metal chelates exhibit higher activity in comparison with that of the free ligand or the control (ampicillin). The zone of inhibition values of the ligand and the complexes against the growth microorganisms are summarized in Table-3. The chloro complexes are found to be more active than the acetato and nitrato complexes.

### Table-3

| Compound       | S. aureus | E. coli | P. aeruginosa | K. pneumoniae |
|----------------|-----------|---------|---------------|---------------|
| Ampicillin     | 10        | 12      | 15            | 12            |
| MBS           | 8         | 10      | 9             | 8             |
| [Th(MBS)3Cl]  | 19        | 20      | 21            | 22            |
| [Th(MBS)3NO3] | 16        | 15      | 16            | 13            |
| [Th(MBS)3NCS] | 17        | 15      | 14            | 14            |
| [Th(MBS)3ClO4] | 15       | 17      | 16            | 15            |
| [Th(MBS)3OAc] | 14        | 16      | 15            | 14            |

On the basis of the above studies, it is concluded that the present metal chelates have the general structure \([\text{Th(MBS)3X}]\) where \(X = \text{NO}_3^-, \text{Cl}^-, \text{SCN}^-, \text{CH}_3\text{COO}^-\) or \(\text{ClO}_4^-\). Thus, the metal chelates may be represented as in Fig. 2 in which the coordination number of thorium is seven.

complexes. On the other hand, in the case of S-bonded complexes several bands with lower intensities appear around 420 cm\(^{-1}\). Thus, it is evident that the thiocyanate ion is coordinated unidentately to the thorium ion through N atom.

In the IR spectrum of acetato complex two additional bands are present at 1671 and 1322 cm\(^{-1}\) corresponding to asymmetric and symmetric stretching vibrations of carboxylate group. The \(v_{asym}\) and \(v_{sym}\) modes of the carboxylate ion in the free acid appears at 1560 and 1420 cm\(^{-1}\), respectively. But, in the spectrum of the complex \(v_{sym}(OCO)\) mode is shifted to higher frequency, 1671 cm\(^{-1}\) whereas \(v_{asym}(OCO)\) is shifted to lower frequency, 1322 cm\(^{-1}\). Thus, the separation between the two \(v(OCO)\) bands increases which indicates the unidentate coordination of acetato ion to thorium ion. The nonelectrolytic conductance value of the complex agrees with this conclusion.

The infrared spectrum of the perchlorato complex exhibits three additional bands at 1102, 1082 and 621 cm\(^{-1}\) corresponding to \(v_n\), \(v_1\) and \(v_3\) modes of coordinated perchlorate ion. This indicates the unidentate coordination of ClO\(_4^-\) to Th(IV) ion. The non-electrolytic conductance value of the complex agrees with this conclusion.

The \(^1\)H NMR spectra of MBS and [Th(MBS)3Cl] were recorded in DMSO-\(d_6\) solution. The ligand exhibits a multiplet signal at \(\delta\) 6.96-7.82 ppm which is due to the presence of aromatic protons. Signals at \(\delta\) 6.62 ppm due to CH group, at \(\delta\) 3.8 ppm due to morpholine O-CH\(_2\), at \(\delta\) 6.14 due to NH proton, at \(\delta\) 2.3 due to morpholine –N-CH\(_2\), at \(\delta\) 3.8 ppm due to morpholine O-CH\(_2\). The singlet at \(\delta\) 10.8 ppm is due to –N=C-OH group. In the metal chelates, the multiplet at \(\delta\) 7.16-7.20 ppm and at \(\delta\) 7.9-8.08 ppm is due the presence of aromatic protons. The downfield shifting of –CH and –NH protons indicates the coordination of azomethine nitrogen. The missing of the peak at \(\delta\) 10.8 ppm of MBS in the complex confirms that the ligand is in enol form and it undergoes deprotonation followed by coordination of the carboxyl oxygen with the metal.

The mass spectrum of the ligand, MBS exhibits a molecular ion peak at \(m/z\) 25. The metal chelate, [Th(MBS)3Cl] shows the molecular ion peak at \(m/z\) 1015. The ligand as well as the metal chelate exhibit the base peak at \(m/z\) 164 due to the fragment, \(\text{C}_6\text{H}_8\text{N}_2\text{O}\).

The X-ray powder patterns of the complexes [Th(MBS)3Cl] and [Th(MBS)3NO3] were recorded on a Rigaku (Japan) PW 1710 X-ray powder diffractometer on a chart recorder. The diffraction patterns were indexed by using the method developed by Hesse [21] and Lipson and Steeple [22]. The complexes were found to be orthorhombic. The unit cell dimensions of the complex, [Th(MBS)3Cl] are : \(a = 17.9743\) Å, \(b = 11.4783\) Å and \(c = 8.7975\) Å. Thus the cell volume (V) of the complex is 1.8151 × 10\(^{21}\) cm\(^3\). The density of the complex is 0.9264 g cm\(^{-3}\). From these values n is given as \(\frac{dN_n V}{M} = 0.9969\). Thus it is evident that the number of molecules per unit cell is one. In the case of the complex, [Th(MBS)3NO3], the unit cell dimensions were found to be \(a = 18.2868\) Å, \(b = 11.6780\) Å and \(c = 8.9505\) Å and the cell volume (V) is 1.8151 × 10\(^{21}\) g cm\(^{-3}\). Evidently the number of molecules per unit cell, \(n = \frac{dN_n V}{M} = 1.0291\), *i.e.*, one per unit cell.

The zone of inhibition values of the ligand and the complexes against the growth microorganisms are summarized in Table-3. The chloro complexes are found to be more active than the acetato and nitrato complexes.

The non-electrolytic conductance value of the complex agrees with this conclusion.
