Abstract

In this paper, \( \Phi \)-pseudo-contractive operators and \( \Phi \)-accretive operators, more general than the strongly pseudo-contractive operators and strongly accretive operators, are introduced. By to set up a new inequality, authors proved that if \( T : X \to X \) is an uniformly continuous \( \Phi \)-pseudo-contractive operator then \( T \) has unique fixed point \( q \) and the Mann iterative sequence with random errors approximates to \( q \). As an application, the iterative solution of nonlinear equation with \( \Phi \)-accretive operator are obtained. The results presented in this paper improve and generalize some corresponding results in recent literature.

Keywords: Duality mapping; \( \Phi \)-pseudo-contractive operator; \( \Phi \)-accretive operator; Mann iterative sequence with random error terms

1. Introduction and Preliminaries

In 1994, Chidume[1] solved a problem deals with the fixed point for the class of Lipschitz strictly(strongly) pseudo-contractive operators in uniformly smooth Banach space \( X \). That is, he proved that the Ishikawa iterative sequence converges strongly to the unique fixed point of \( T \) in \( K \) where \( K \subset X \) and \( T : K \to K \) is Lipschitz strictly(strongly) pseudo-contractive. Chang [2], in 1998, improved the result, i.e., he proved that the conclusion of Chidume holds if \( T \) is uniformly continuous and the fixed point set of \( T \) is nonempty(i.e., \( f(T) \neq \emptyset \)). Recently, Liu[3] proved, if the strongly pseudocontractive operators are replaced by the more general \( \phi \)-strongly pseudo-contractive operators then the conclusion of Chidume still holds.

The objective of this paper is to introduce \( \Phi \)-pseudo-contractive operators — a class of operators which is more general than the \( \phi \)-strongly pseudo-contractive operators and to study the problems of existence, uniqueness and the iterative approximate method of fixed point by to set up a new inequality in arbitrary Banach space. As an application, the iterative solution of nonlinear equation with \( \Phi \)-accretive operator is obtained. The results presented in this paper improve and generalize the conclusions of Chidume, Chang and Liu.

To set the framework, we recall some basic notations as follows.

Throughout this paper, we assume that \( X \) is a real Banach space with dual \( X^* \), \( (\cdot, \cdot) \) denotes the generalized duality pairing. The mapping \( J : X \to 2^{X^*} \) defined by

\[
J_x = \{ j \in X^* : (x,j) = \|x\|\|j\| \quad \forall x \in X \}
\]

(1)

is called the normalized duality mapping[4].

Now, we introduce \( \Phi \)-pseudo-contractive operators as follows.

Definition 1. Let \( K \) be nonempty subset of \( X \). An operator \( T : K \to K \) is said to be \( \Phi \)-pseudo-contractive, if there exists a strictly increasing function \( \Phi : [0,\infty) \to [0,\infty) \) with \( \Phi(0) = 0 \) and

\[
j(x - y) \in J(x - y) \quad \text{such that} \quad (Tx - Ty, j(x - y)) \leq \|x - y\| - \Phi(\|x - y\|) \quad \forall x, y \in K.
\]

(2)

An operator \( A : K \to K \) is said to be \( \Phi \)-accretive, if

\[
(Ax - Ay, j(x - y)) \geq \Phi(\|x - y\|) \quad \forall x, y \in K.
\]

(3)

It is easy to verify that the operator \( T \) is \( \Phi \)-pseudo-accretive if and only if \( I - T \) is \( \Phi \)-accretive where \( I \) is a identity mapping on \( X \). Hence, the mapping theory for accretive operators is intimately con-
nected with the fixed point theory for pseudo-contractive operators.

We like to point out: every strongly pseudo-contractive operator is \( \phi \)-strongly pseudo-contractive with \( \phi : [0, \infty) \rightarrow [0, \infty) \) defined by \( \phi(s) = ks \) where \( k \in (0,1) \), and every \( \phi \)-strongly pseudo-contractive operator must be the \( \Phi \)-pseudo-contractive operator with \( \Phi : [0, \infty) \rightarrow [0, \infty) \) defined by \( \Phi(s) = \phi(s) s \).

Obvious, if a \( \Phi \)-pseudo-contractive operator has a fixed point then it is unique.

**Definition 2.** Let \( T : K \rightarrow K \) be an operator. For any given \( x_0 \in K \) the sequence \( \{x_n\} \) defined by

\[
x_{n+1} = (1-\alpha_n)x_n + \alpha_n Tx_n + \gamma_n u_n \quad (n \geq 0)
\]

is called Mann iteration sequence with random errors. Here \( \{\alpha_n\} \) is a bounded sequence in \( [0,1] \) and is said random error terms of iterative process, and the parameters \( \{\alpha_n\} \) and \( \{\gamma_n\} \) both are sequences in \( [0,1] \). By the way, Xu introduced another definition of Mann iterative sequence with random errors in [5].

In particular, the parameters \( \gamma_n = 0 \) for all \( n \geq 0 \) in equation (4) then \( \{x_n\} \) is called Mann [6] iteration sequence.

### 2. Main Results

First, we have an existence theorem of fixed point as follow.

**Theorem 1.** If \( T : X \rightarrow X \) is a continuous \( \Phi \)-pseudo-contractive operator with bounded range then \( T \) has an unique fixed point in \( X \).

**Proof.** Define \( T_0 : X \rightarrow X \) by

\[
T_0x = x - c_0Tx \quad \forall x \in X \quad \text{and} \quad n \geq 1
\]

where \( c_0 \in (0,1) \) and \( \lim_{n \to \infty} c_n = 1 \). Note that \( T_0 \) is \( \Phi \)-pseudo-contractive, thus

\[
(T_0x - T_0y, (x-y)) = (x-y, -c_0(Tx-Ty, (x-y))) \\
\geq (1-c_0)(\|x-y\| - c_0\|Tx-Ty\|)
\]

\[
\geq c_0\|x-y\| - c_0\|Tx-Ty\| \\
\geq c_0\|x-y\| - c_0\|x-y\| = 0
\]

for all \( x, y \geq X, n \geq 1 \) and some \( (x-y) \in J_0(x+y) \).

Clearly, \( T_0 \) is a continuous strongly accretive operator. It follows from the Theorem 13.1 of Deimling [7] that there exists \( x_0 \in X \) such that \( T_0x_0 = 0 \) for any \( n \geq 1 \).

Next, the sequence \( \{x_n\} \) is bounded. In fact, if

\[
\|x\| \leq M \quad \text{then} \quad \|x_n\| \leq M \quad \forall x \in X
\]

\[
\lim_{n \to \infty} \|x_n - Tx_n\| = \lim_{n \to \infty} (1-c_n)\|x_n^0\| = 0
\]

(6)

Since \( T \) is \( \Phi \)-pseudo-contractive, that is, \( (I-T) \) is \( \Phi \)-accretive, so

\[
\Phi(\|x_n - x_k\|) \leq ((I-T)x_n - (I-T)x_k, J(x_n - x_k)) \\
\leq (\|x_n - Tx_n\| + \|x_k - Tx_k\|)\|x_n - x_k\| \\
\leq 2M(\|x_n - Tx_n\| + \|x_k - Tx_k\|)
\]

(7)

for any \( x_n, x_k \in \{x_n\} \). Equations of (6) and (7) ensure that \( \{x_n\} \) is a Cauchy sequence.

Consequently, \( \{x_n\} \) converges to some \( q \in X \). By the continuity of \( T \) we have

\[
Tq = \lim_{n \to \infty} Tx_n = \lim_{n \to \infty} x_n = q
\]

Suppose that there exists a \( q' \in X \) such that \( Tq' = q' \) then

\[
\Phi(\|q - q'\|) \leq \|q' - q\| - (Tq - Tq', J(q - q')) = 0
\]

which means that \( q = q' \). I.e., \( q \) is unique fixed point of \( T \). The proof is completed. \( \Box \)

The following two Lemmas will play crucial roles in the proof of Theorem 2.

**Lemma 1.** [2] If \( X \) be a real Banach space then there exists \( j(x+y) \in J(x+y) \) such that

\[
\|x+y\| \leq \|x\| + 2\|y, j(x+y)\| \quad \forall x, y \in X
\]

(8)

Second, to set up a new inequality as follows.

**Lemma 2.** Let \( \Phi : [0, \infty) \rightarrow [0, \infty) \) be a strictly increasing function with \( \Phi(0) = 0 \) and let \( \{a_n\} \) and \( \{c_n\} \) be two nonnegative real sequences satisfying

\[
\sum_{n \geq 0} a_n < \infty, \quad \sum_{n \geq 0} c_n = \infty \quad \text{and} \quad \lim_{n \to \infty} c_n = 0
\]

(9)

Suppose \( \{a_n\} \) is a nonnegative real sequences. If there exists an integer \( N \) satisfying

\[
a_{n+1} \leq a_n + o(a_n) + c_n \quad \forall n \geq N
\]

(10)

then \( \lim_{n \to \infty} a_n \) is bounded. In fact, if \( \sigma > 0 \), then \( \Phi(a_{n+1}) > \Phi(\sigma) \) for all \( n \geq 0 \). From the conditions of equation (9) there exists an integer \( N > 0 \) such that

\[
2o(a_n) \leq \Phi(\sigma)c_n \quad \forall n \geq N
\]

(11)

So, we have
\[ a_{i}^{j} \leq a_{i}^{j} + c_{a} - \frac{1}{2} \Phi(\sigma) b_{a} \quad \forall n \geq N. \]

By induction, we obtain
\[ \frac{1}{2} \Phi(\sigma) \sum_{j=1}^{n} b_{j} \leq a_{i}^{j} + \sum_{j=1}^{n} c_{a} < +\infty. \]  

(12)
equation (12) is in contradiction with \( \sum_{j=1}^{n} b_{j} = +\infty \). It implies that \( \sigma = 0 \). Therefore, there exists a subsequence \( \{a_{n_{j}}\} \subset \{a_{n}\} \) such that \( \lim_{j \to \infty} a_{n_{j}} = 0 \). So, for any given \( \varepsilon > 0 \) there exists an integer \( j_{\varepsilon} \geq 0 \) such that
\[ a_{n_{j}} < \varepsilon \quad \forall j \geq j_{\varepsilon} \text{ and} \quad o(b_{j}) + c_{a} \leq \Phi(\varepsilon) b_{a} \quad \forall n \geq n_{\varepsilon} > 0. \]

(13)
If \( j_{\varepsilon} \) is fixed, we will prove that \( a_{n_{j_{\varepsilon}} < \varepsilon} \) for all integers \( k \geq 1 \). The proof is by induction. For \( k = 1 \), suppose \( a_{n_{j_{\varepsilon}} < \varepsilon} \). It follows from equations (10) and (13) that
\[ \varepsilon^{j} \leq a_{n_{j_{\varepsilon}}}^{j} \leq a_{n_{j_{\varepsilon}}} + o(b_{j}) + c_{a} - \Phi(\varepsilon) b_{a} \leq a_{n_{j_{\varepsilon}}}^{j} < \varepsilon^{j}. \]

It is a contradiction. Hence, \( a_{n_{j_{\varepsilon}} < \varepsilon} \) holds for \( k = 1 \).

Assume now that \( a_{n_{j_{p+1}} < \varepsilon} \) for some integer \( p > 1 \). We prove that \( a_{n_{j_{p+2}} < \varepsilon} \). Again, assuming the contrary, Using equations (10) and (13), as above, it leads to a contradiction as follows
\[ \varepsilon^{j} \leq a_{n_{j_{p+2}}}^{j} \leq a_{n_{j_{p+2}}} + o(b_{j}) + c_{a} - \Phi(\varepsilon) b_{a} \leq a_{n_{j_{p+2}}}^{j} < \varepsilon^{j}. \]

Where \( n_{p} + p \geq n_{j_{p}} > j_{\varepsilon} \). Therefore, \( a_{n_{j_{p+2}} < \varepsilon} \) holds for all integers \( k \geq 1 \), i.e., \( \lim_{es} a_{n_{j_{p}}} = \lim_{es} a_{n_{j_{p+1}}} = 0 \).

The Proof is completed. □

**Theorem 2.** Let \( T : X \to X \) be an uniformly continuous \( \Phi \)-pseudo-contractive operator with bounded range. Suppose that the iterative sequence \( \{x_{n}\} \) is defined by equation (4) satisfying
\[ \sum_{n=1}^{\infty} r_{n} < \infty, \quad \lim_{n \to \infty} a_{n} = 0 \quad \text{and} \quad \sum_{n=1}^{\infty} a_{n} = \infty. \]

(14)
then \( \{x_{n}\} \) converges strongly to unique fixed point of \( T \).

**Proof.** From Theorem 1, we know that there exists a unique fixed point \( q \) of \( T \).

Putting \( M_{q} = \sup \{\|x\| : x \in X\} + \sup \{\|r_{n}\| : n \geq 0\} + \|s\| \) for any given \( x_{0} \in X \), then
\[ \|r_{n}\| \leq (1 - a_{n}) \|x_{n}\| + a_{n} \|x_{n}\| \leq M_{q}. \]

Using induction, we have \( \|r_{n}\| \leq M_{q} \) for all \( n \geq 0 \). Let \( M = M_{q} + \|s\| \). Since
\[ \|x_{n} - x_{n-1}\| = a_{n} \|x_{n} - T_{x_{n}}\| - 2Ma_{n} \to 0 \text{ (as } n \to \infty) \]
then,
\[ e_{n} := \|x_{n} - T_{x_{n}}\| \to 0 \text{ (as } n \to \infty) \]
by the uniformly continuity of \( T \).

From equation (14) there exists an integer \( N_{\varepsilon} > 0 \) such that
\[ 0 \leq a_{n} < \frac{1}{6} \quad \forall n \geq N_{\varepsilon}. \]

(15)
By equations (4), (8) and (15) we have
\[ 0 < \|x_{n} - q\| - \|(1 - a_{n})(x_{n} - q) + a_{n}(Tx_{n} - q) + \gamma_{n}r_{n}\| \leq (1 - a_{n}) \|x_{n} - q\| + 2a_{n} \|x_{n} - q\| + 2a_{n} \|\gamma_{n}r_{n}\| \]
\[ \leq (1 - a_{n}) \|x_{n} - q\| + 2a_{n} \|x_{n} - q\| + 2M \|\gamma_{n}\| \leq (1 - 2a_{n} + a_{n}^{2}) \|x_{n} - q\| + 2a_{n} \|\gamma_{n}\| + 2M \|\gamma_{n}\| \leq \|x_{n} - q\| + 2M \|x_{n\} \| - 2a_{n} \|\gamma_{n}\| - 2a_{n} \|\gamma_{n}\| + 2M \|\gamma_{n}\| \]
for all \( n \geq N_{\varepsilon} \) where \( o(a_{n}) = 2M \|x_{n\} \| + 3Ma_{n} e_{n} \) and \( e_{n} = 2M \|\gamma_{n}\| \). It follows from the Lemma 2 that \( \lim_{n \to \infty} \|x_{n} - q\| = 0 \). The Proof is completed. □

Last, as an application, the existence, the uniqueness and the approximate method of solution of nonlinear equation with \( \Phi \)-accretive operator is obtained. That is

**Theorem 3.** Suppose that \( A : X \to X \) is an uniformly continuous \( \Phi \)-accretive operator and the range of either \( A \) or \( I - A \) be bounded. For any given \( f \in X \), the equation \( Ax = f \) has unique solution in \( X \), and if \( \{x_{n}\} \) is defined by
\[ x_{n+1} = (1 - a_{n})x_{n} + a_{n}[f + (I - A)x_{n} + \gamma_{n}r_{n}], \quad (n \geq 0) \]
satisfying the conditions of equation (14) then \( \{x_{n}\} \) converges strongly to the solution.

**Proof.** We define \( S : X \to X \) by \( Sx = f + x - Ax \) for all \( x \in X \). Clearly, \( S \) is \( \Phi \)-pseudo-contractive and con-

Copyright © 2013 SciRes.
continuous if $A$ is Φ-accretive and continuous, and the range of $S$ is bounded if $(I - A)$ is. It is easy to see that $x^*$ is a solution of the equation $Ax = f$ if and only if that $x^*$ is a fixed point of $S$. It follows from the Theorem 2 that $Ax = f$ has an unique solution $x^* \in X$ and the iterative sequence $\{x_n\}$ is defined by equation (4) converges strongly to $x^*$. I.e., the sequence $\{x_n\}$ is an iterative solution of the equation $Ax = f$.

The proof is completed. □

Remark. Theorem 2 improves a number of results (for example, Theorem 4.2 of [2], Theorem 2 of [1] and Corollary 3.3 and 3.4 of [3]) in the following senses.
1) The existence and the convergence of the fixed point for Φ-pseudo-contractive operator are studied simultaneously.
2) The operators may not be strongly pseudo-contractive or $\phi$-strongly pseudo-contractive.
3) The continuity of operator may not be Lipschitzian.
4) The errors come from the iterative process have been considered appropriately.
