Symmetry Analysis of Multiferroic Co₃TeO₆

A. B. Harris

1Department of Physics and Astronomy, University of Pennsylvania, Philadelphia PA 19104

(Dated: February 17, 2012)

A phenomenological explanation of the magnetoelectric behavior of Co₃TeO₆ is developed. We explain the second harmonic generation data and the magnetic field induced spontaneous electric polarization in the magnetically ordered phase below 20K.

I. INTRODUCTION

Recently there has been an explosion in the number of compounds which exhibit nontrivial magnetoelectric behavior at low temperatures. Co₃TeO₆ (CTO) is an interesting system whose properties have recently been studied. Although the magnetic structure is as yet not clarified, it seems useful to construct a mean-field scenario which can explain the major experimental results. The measurements of Hudl et al. 6 of M/H, d(M/H)/dT, and C/T versus T, where M is the magnetization, H the magnetic field, and C the specific heat, indicate that there are two second magnetic phase transitions at temperatures below about 30K, one at T₁ ≈ 26K and another at T₂ ≈ 18.5K, but the details of the magnetic structure are not known, other than that the system is not ferromagnetic. According to Ref. 6, the magnetic structure is described by several incommensurate wave vectors. Single crystal neutron diffraction measurements reveal that the incommensurate wave vector(s) are in the a-b plane and not along c. 8 We propose the existence of magnetic order at zero wave vector, consistent with the results of Li et al., although, this would have to involve an antiferromagnetic arrangement of moments within the unit cell to give the observed zero net moment. In addition, our analysis suggests the appearance of an additional magnetic phase transition. In the absence of magnetic order the crystal symmetry is mm̅2 that of space group C2/c (≠15 in Ref. 10). We will take the generators of this space group to be the glide operation mₙ ≡ (x, −y, z + 1/2), a two-fold screw rotation about the crystal b axis, 2ₙ ≡ (−x, y + 1/2, −z + 1/2), and the three translations, (x + 1/2, y + 1/2, z), (x + 1/2, y + 1/2, z), and (x, y, z + 1), where x, y, and z are in units of lattice constants. These are equivalent to those of Ref. 11.

II. EXPERIMENTAL DATA

The data of Hudl et al. 6 consist of several types. As mentioned above, the measurements of magnetization and specific heat indicate phase transitions at at least two temperatures, T₁ and T₂, but the nature of magnetic ordering could not be determined from their data. The lower-temperature transition may be a discontinuous one. Of primary interest to us is their measurement of the intensity of second harmonic generation (SHG), whose cross section is proportional to the third order electric susceptibility χαβγ, where α, β and γ label components (or in the present case label crystallographic directions). Their experimental geometries are chosen such that the SHG cross section is proportional to χaaa. In a system having high symmetry, e.g. having inversion symmetry, the SHG intensity is zero for all frequencies, and this applies to CTO above about T₂ = 18.5K. However, below that temperature they find that χaaa and χabc are nonzero, but χaba is apparently zero at all temperatures. From this they conclude that the point group retains only mₙ symmetry. As we shall see, if, as they assert, the symmetry is magnetically broken, this is not a correct conclusion.

Another type of data of crucial interest to us the measurement of the electric polarization, P in the a-c plane, as a function of temperature and magnetic field for magnetic fields along the crystallographic a and c directions. For zero magnetic field, at temperatures below about 18K, they find a very small, possibly zero, spontaneous polarization in the a and c directions which increases almost proportional to the magnetic field. In fact, we find that their results for Pₑ at T = 5K as a function of Hₐ can be fit within experimental uncertainty (±5 in Pₑ) to

$$Pₑ = -0.15 + 6.93Hₐ + 0.33H_a^2$$

with Pₑ in μC/m² and H in Tesla. In other words, they found an important magnetic field-dependent contribution to Pₑ linear in Hₐ with Pₑ(Hₐ = 0) ≈ 0.

III. SYMMETRY ANALYSIS

We will carry out our analysis in terms of an expansion about the “vacuum”, which we take to be the phase above 26K in which the magnetic order parameters and electric polarization are zero. Magnetically ordered phases are described by nonzero magnetic order parameters. We will also discuss briefly nonmagnetic structural distortions which lower the crystal symmetry from C2/c and which are described by appropriate order parameters. Although, as mentioned in Ref. 6, there may exist incommensurate magnetic order described by M(q) with q ≠ 0, incommensurate magnetic order can not, by itself, explain the experimental results, as we will explain...
below.

A. Electric Polarization

We first review the phenomenological theory of magnetoelectric free energy of the form
\[ F_{ME} = \frac{1}{2} \chi_E^{-1} \mathbf{P}^2 + \sum_n \Delta F^{(n)} , \]
where \( \chi_E \) is the dielectric susceptibility of the vacuum (the phase above \( T = 26K \)), which we assume to be isotropic for simplicity and \( \Delta F^{(n)} \) is the contribution linear in \( \mathbf{P} \) (so that it induces a nonzero value of \( \mathbf{P} \)) and of order \( H^n \). For instance, to lowest order in powers of the magnetic order parameters, we write\[ \Delta F^{(0)} = \sum_{q \neq 0} a_{\alpha k}(q) P_\alpha [M_k(q)^* M_l(q) - M_k(q) M_l(q)^*] \]
+ \[ \Delta F^{(1)} = c_{\alpha \beta k} P_\alpha H_\beta M_k(q) = 0 \]
+ \[ \Delta F^{(2)} = \sum_{q \neq 0} d_{\alpha \beta \gamma k} (q) P_\alpha H_\beta H_\gamma \times [M_k(q)^* M_l(q) - M_k(q) M_l(q)^*] \]
+ \[ c_{\alpha \beta \gamma k}(q) P_\alpha H_\beta H_\gamma M_k(q) M_l(q) \]
where we invoke the Einstein convention which implies summation over repeated subscripts, Greek subscripts label crystallographic directions, and Roman letters label irreducible representations (irreps), which in the present case are one dimensional. The magnetic order parameter \( M_k(q) \) can be thought of as the amplitude of the magnetic normal mode associated with irrep \( \Gamma_k \). These normal modes are the linear combinations of magnetic moments within the unit which bring the quadratic terms in the Landau expansion into diagonal form. We will discuss the symmetry of the \( M_k \)'s in a moment. Here the Fourier transforms are defined so that for \( q \neq 0 \), \( \mathcal{F} M_k(q)^* = M_k(q)^* \), where \( \mathcal{F} \) is a spatial inversion.

\( F_{ME} \) must be invariant under all the symmetries of the “vacuum.” These symmetries include time reversal symmetry, translational symmetry (which leads to wave vector conservation), and the crystallographic symmetries \( m_b \) and \( 2 \alpha_0 \) (which together imply invariance under spatial inversion \( \mathcal{I} \)). We will consider the crystallographic symmetries in a moment. Time reversal symmetry requires that the total number of powers of \( H \) and \( M(q) \) must be even. The condition that \( F_{ME} \) be real valued implies that \( a(q) \) and \( d(q) \) be pure imaginary. The form of \( \Delta F^{(1)} \) is such that wave vector conservation implies that the magnetic order for this mechanism must occur at zero wave vector, and, as previously noted, it must be antiferromagnetic to be consistent with the observed zero net magnetic moment of the system. (In fact CTO has a large enough paramagnetic unit cell that antiferromagnetic order can develop without increasing the size of the unit cell, as occurs in LaTiO3,\[ 13 \]and Cr2O3,\[ 14 \].) Such an antiferromagnetic moment would be consistent with the magnetic measurements of Hudl et al.\[ 6 \]

When \( F_{ME} \) is minimized with respect to \( \mathbf{P} \) to obtain its equilibrium value, one sees that \( \Delta F^{(n)} \) gives rise to a contribution to \( \mathbf{P} \) which is of order \( H^n \). In many multiferroics, such as Ni3V2O8\[ 20 \] (NVO) and TbMnO3\[ 21 \] (TMO), \( \Delta F^{(0)} \) is a crucial term which gives rise to a spontaneous polarization at \( H = 0 \). Many other cases are similarly analyzed in Ref.\[ 3 \]. In these cases, the magnetic order is incommensurate, so that the polarization (a zero wave vector property) can not be linear in the magnetic order parameter. Since in CTO \( \mathbf{P} \propto H \), we consider \( \Delta F^{(1)} \) from which we get
\[ P_\alpha = \chi_E \sum_{\beta k} c_{\alpha \beta k} H_\beta M_k . \]

We now show how the crystallographic symmetries constrain the coefficient tensor \( c_{\alpha \beta k} \). In particular, we will show that these symmetries fix the symmetry of \( M_k \). For this purpose, note that \( \Delta F^{(1)} \) has to be invariant under these symmetries. In this analysis, we will confine \( \mathbf{P} \) and \( \mathbf{H} \) to be perpendicular to the crystallographic \( \mathbf{b} \) direction, as they were in the experiments of Ref.\[ 3 \]. In that case, we only consider terms in \( \Delta F^{(1)} \) with \( \alpha \) and \( \beta \) labeling the crystallographic \( a \) and \( c \) directions, and \( k \) labels the possible magnetic irreps at zero wave vector. Remembering that \( \mathbf{H} \) is a pseudovector, we note that
\[ m_b [P_\alpha H_\beta] = -P_\alpha H_\beta , \]
\[ 2b [P_\alpha H_\beta] = P_\alpha H_\beta . \]

Accordingly, for \( \Delta F^{(1)} \) to be an invariant we require that
\[ m_b M_k = -M_k , \]
\[ 2b M_k = M_k . \]

To implement Eq. (6) we need to characterize the symmetry of the magnetic ordering, which we have inferred occurs at zero wave vector. For phase transitions the catalog of broken symmetry phases that can result from a phase transition in any of the 230 crystallographic space groups can be obtained using the suite of computer programs ISODISTORT which is accessible on the web.\[ 15 \]

As applied to CTO one predicts that only four magnetic irreps can result from a single phase transition at zero wave vector. This formulation specifically does not allow for a multicritical point at which there is a simultaneous breaking of two distinct symmetries. For CTO there is no experimental indication that the magnetic phase transitions arise from such a multicritical point.\[ 16 \]

Therefore we assume the validity of the four possible magnetic phases of Table\[ 4 \] which ISODISTORT lists for space group C2/c. Looking at Table\[ 4 \] we see that to be consistent with Eq. (6), the magnetic order parameter can only be that of irrep \( \Gamma_2 \).

B. Second Harmonic Generation

We now turn to the analysis of the SHG cross section at \( H = 0 \). To develop a nonzero SHG cross sec-
TABLE I: Symmetry of the magnetic irreps $\Gamma_n$ at zero wave vector for CTO. Here $\lambda(\mathcal{O})$ is the eigenvalue of the operator $\mathcal{O}$: $\mathcal{O}M = \lambda(\mathcal{O})M$, where $M_k = M(\Gamma_k)$ is the order parameter associated with the $k$th irrep. Also $\mathcal{E}$ is the identity and $\mathcal{I}$ is spatial inversion. In the last line, we give the direction of the ferromagnetic moment if it is allowed to be nonzero.

| $\lambda(\mathcal{E})$ | $\lambda(2\mathcal{E})$ | $\lambda(m_k)$ | $\lambda(\mathcal{I})$ | $M$ |
|----------------------|----------------------|----------------|---------------------|-----|
| $-1$                 | $+1$                 | $-1$          | $+1$                | $b$ |
| $+1$                 | $-1$                 | $-1$          | $-1$                | $0$ |

In the first scenario, we assume that the nonzero SHG cross section is induced by magnetic order at zero wave vector and study the symmetry properties of $X_n$. Since $p^2$ transforms like unity, it suffices to study $X_n \equiv p_\alpha M_k M_l$, to indicate whether $\chi_{\alpha\alpha\alpha}$ is or is not zero. Since $\chi_{\alpha\beta\beta} = 0$, we require that $p_\alpha M_k M_l$ be odd under either $m_b$ or $2b$. This implies that $M_k M_l$ either be even under $m_b$ or odd under $2b$. Using Table III we see that this criterion excludes either $M_1 M_2$ or $M_3 M_4$ being nonzero. Similarly if $\chi_{\alpha\alpha\alpha}$ and $\chi_{\alpha\alpha\alpha}$ are nonzero, we require that both $p_\alpha M_k M_l$ and $p_\alpha M_k M_l$ be even under both $m_b$ and $2b$. This implies that $M_k M_l$ be even under $m_b$ and odd under $2b$. These requirements indicate that either $M_1 M_4$ or $M_2 M_3$ is nonzero. Since we have previously invoked the existence of irrep $M_2$ to explain the electric polarization, we opt for $M_2 M_3$ being nonzero. The fact that the magnetic moment perpendicular to $b$ (coming from irrep $M_3$) is zero (or very small) would have to be a result specific to the details of the interactions.

In the second scenario one would have to posit an additional phase transition involving a second incommensurate magnetic irrep to give rise to a nonzero SHG cross section. In principle, one would have an accompanying field independent polarization coming from $\Delta F^{(0)}$, whose absence in experiment would have to be explained as above in terms an unusually large SHG cross section. To illustrate this mechanism consider the hypothetical case when the incommensurate magnetic ordering occurs at $q = q_0 b$. In this case one finds that there are two magnetic irreps, one of which, call it $M_1(q)$, is even under $2b$ and the other, call it $M_2(q)$, is odd under $2b$. Then one sees that $X \equiv p_\alpha[M_1(q)^* M_2(q) - M_1(q) M_2(q)^*]$ and $Y \equiv p_\alpha[M_1(q)^* M_2(q) - M_1(q) M_2(q)^*]$ are both invariant under $2b$ (and under $T$), so that $\chi_{\alpha\alpha\alpha} \times X$ and $\chi_{\alpha\alpha\alpha} \times Y$ are allowed to be nonzero, whereas $\chi_{\alpha\alpha\alpha}$ remains zero. In a common scenario one irrep would give rise to nonzero magnetic moments along the $b$ axis, and the other would give rise to nonzero magnetic moments along the $c$ axis. These irreps would be out of phase (so that $M_1(q)^* M_2(q) - M_1(q) M_2(q)^*$ is nonzero) giving rise to a magnetic spiral.

TABLE II: As Table III Symmetry of the product of two zero wave vector magnetic irreps $\Gamma_n$ for CTO.

| $\lambda(2\mathcal{E})$ | $\lambda(m_k)$ |
|----------------------|----------------|
| $+1$                 | $-1$          |
| $-1$                 | $+1$          |
| $-1$                 | $-1$          |
| $+1$                 | $+1$          |

C. Discussion

To summarize our conclusions: we require the existence of zero wavevector magnetism according to irrep $M_2$ to explain the magnetic field induced electric polarization. In one scenario we explain the SHG cross section as being proportional to $M_2 M_3$. Since we prefer not to
assume a multicritical point, the latter result would imply that there are actually two phase transitions. At the higher-temperature transition (at $T = 18.5\text{K}$) a magnetic field induced spontaneous electric polarization appears and at the lower-temperature transition (at some temperature close to but below 18.5K) the SHG cross section becomes nonzero. Here a very small magnetic field independent polarization should also appear. In principle, one would hope to show the temperature dependence of the SHG cross section to be proportional to the product of these two order parameters whose temperature dependence was independently established by neutron diffraction. This type of experimental program was carried out for the electric polarization of NVO (see Fig. 6 of Ref. 20). Note also a magnetically induced SHG cross section implies that the symmetry involves time reversal. The magnetic phase with irrep $M_2$ is odd under $m_b$, as indicated in Table I. In contrast, if we were dealing with a nonmagnetic structural phase transition, as the analysis of Hudl et al. tacitly assumes, then the low-temperature phase would be even under $m_b$, as they state. However, note that the presence of magnetic irreps $M_2$ and $M_3$ breaks the mirror symmetry of $m_b$, but the symmetry of $m_b$ plus time reversal is maintained. This is consistent with the results of Tables 7 and 4 of Ref. 22. (The misidentification of Ref. 6 is not completely harmless. Even if it is assumed, then the low-temperature phase is not completely nonmagnetic. If one assumes that $m_b$ symmetry is unbroken, then, as they find, it is impossible to use $\Delta F^{(1)}$ to explain why $\partial F_\alpha/\partial H_\beta$ is nonzero for $\alpha, \beta = a, c$.)

The second scenario has similar ramifications except that it involves magnetic ordering at some incommensurate wave vector. This scenario would also require a second phase transition at which a second incommensurate order parameter would appear. In principle, such a transition could involve a slightly different wave vector than that already present. But, as argued in Ref. 4, quartic terms in the Landau free energy would favor locking these two nearby wave vectors to the same value.

We have implicitly assumed that the experimental results are induced by magnetic ordering. One might question whether the results of Ref. 6 could be explained by simply invoking one or more phase transitions driven by structural distortions. Since magnetic ordering appears at these transitions the question is which order parameter is the primary one whose presence induces the appearance of the other one. If $Q$ is a structural order parameter (like the tilting angle of a cage of oxygen ions), then one can invoke an interaction of the type $V \sim M(\Gamma_k)M(\Gamma_l)Q$ to explain the appearance of a nonzero value of $Q$ at the transition. Via this coupling the appearance of one or more magnetic order parameters (which are the primary order parameters) would induce a structural distortion (because $Q$ appears linearly). The converse case, where the magnetic order parameter appears linearly and the primary order parameter $Q$ appears quadratically (or linearly, for that matter) is not allowed by time reversal symmetry. But if the magnetic order parameters are the primary ones, then the theoretical approach of the present paper is essentially unchanged by the appearance of secondary structural order parameters.

ACKNOWLEDGEMENT I acknowledge helpful advice on magnetic symmetry from J. Kikkawa and I thank J. Lynn for interesting me in this system. I also gratefully acknowledge support from NIST.
