ON $120$-AVOIDING INVERSION AND ASCENT SEQUENCES

ZHICONG LIN AND SHISHUO FU

Abstract. Recently, Yan and the first named author investigated systematically the enumeration of inversion or ascent sequences avoiding vincular patterns of length 3, where two of the three letters are required to be adjacent. They established many connections with familiar combinatorial families and proposed several interesting conjectures. The objective of this paper is to address two of their conjectures concerning the enumeration of $120$-avoiding inversion or ascent sequences.

1. Introduction

Since the publications of Duncan and Steingrímsson [15], Corteel, Martinez, Savage and Weselcouch [14] and Mansour and Shattuck [24], there has been increasing interest in counting pattern avoiding ascent/inversion sequences [1, 2, 6, 8, 10–12, 19–23, 25, 28, 29]. In particular, motivated by the study of generalized patterns in permutations [4, 13], Yan and the first named author [23] carried out the systematic study of ascent/inversion sequences avoiding vincular patterns of length 3. They reported many nice connections with familiar combinatorial families and posed several challenging enumeration conjectures. The objective of this paper is to address two of their conjectures concerning the pattern $120$ in ascent/inversion sequences. It turns out that $120$-avoiding ascent and inversion sequences possess attractive enumeration results albeit having elusive structure.

Before stating our results, we need to review some definitions on inversion sequences. An integer sequence $e = e_1 e_2 \ldots e_n$ of length $n$ is an inversion sequence if $0 \leq e_i < i$ for all $1 \leq i \leq n$. Inversion sequences of length $n$, denoted $I_n$, are in natural bijection with permutations $S_n$ of $[n] := \{1, 2, \ldots, n\}$ via the famous Lehmer code (see [14, 20]). The set $A_n$ of ascent sequences of length $n$ consists of $e \in I_n$ such that

$$e_{i+1} \leq \text{asc}(e_1 e_2 \ldots e_i) + 1$$

for all $1 \leq i < n$, where $\text{asc}(e_1 e_2 \ldots e_i) := |\{\ell \in [i-1] : e_\ell < e_{\ell+1}\}|$ is the number of ascents of $e_1 e_2 \ldots e_i$. As one of the most important subsets of inversion sequences, ascent sequences were introduced by Bousquet-Mélou, Claesson, Dukes and Kitaev [9] to encode the $(2+2)$-free posets. Many remarkable connections between inversion (resp. ascent) sequences and permutations (resp. restricted permutations) with unexpected applications have been found in the literature; see [17, 20, 27] and the references therein.
Permutations and inversion sequences can both be viewed as words on $\mathbb{N}$. A word $w = w_1w_2 \cdots w_n$ contains a pattern $p = p_1p_2 \cdots p_k$ if there exists $i_1 < i_2 < \cdots < i_k$ such that the subword $w_{i_1}w_{i_2} \cdots w_{i_k}$ of $w$ is order isomorphic to $p$. In addition, if some consecutive letters in a pattern $p$ are underlined, then we further require that in any occurrence of $p$, the letters corresponding to these underlined letters be adjacent in $w$. Such generalized patterns are known as vincular patterns (cf. Kitaev’s book [18, pp.2]), which were introduced in the classification of Mahonian statistics by Babson and Steingrimsson [7]. If a word $w$ does not contain an occurrence of a vincular pattern $p$, then $w$ is said to avoid the pattern $p$. For example, an inversion sequence $e \in \mathcal{I}_n$ is 120-avoiding if there does not exist indices $i$ and $j$, $2 \leq i < j \leq n$, such that $e_j < e_{i-1} < e_i$. For a set $W$ of words, the set of $p$-avoiding words in $W$ is denoted by $W(p)$.

For $n \geq 1$ and $0 \leq k \leq n-1$, let

$$ T(n, k) := \binom{k+2}{2} + n - k - 2 
\frac{n - k - 1}{n - k - 1}. $$

The triangle \{T(n, k)\}_{0 \leq k \leq n-1}^{n \geq 1} is known as the triangle of triangular binomial coefficients and appears as A098568 in the OEIS [26]. Lin and Yan [23] proved that $T(n, k)$ enumerates ascent sequences $e \in \mathcal{A}_n(120)$ with $\text{asc}(e) = k$ and conjectured the following different interpretation.

**Conjecture 1.1** (Lin and Yan [23, Conj. 3.4]). For $n \geq 1$ and $0 \leq k \leq n-1$, we have

$$ |\{e \in \mathcal{A}_n(120) : \text{asc}(e) = k\}| = T(n, k). $$

Following Yan [28], an ascent sequence $e \in \mathcal{A}_n$ is said to be primitive if $e_i \neq e_{i+1}$ for all $i \in [n-1]$. Let $\mathcal{P}\mathcal{A}_n$ be the set of primitive ascent sequences of length $n$. It was observed in [23] that Conjecture 1.1 is equivalent to

$$ |\{e \in \mathcal{P}\mathcal{A}_n(120) : \text{asc}(e) = k\}| = \binom{k+1}{2} \frac{n - k - 1}{n - k - 1}. $$

Alternatively, it suffices to establish the generating function formula

$$ \sum_e x^{\text{len}(e) - k - 1} = (1 + x)^{\binom{k+1}{2}}, $$

where the sum runs over all 120-avoiding primitive inversion sequences with $k$ ascents and $\text{len}(e)$ is the length of $e$. Interestingly, the right-hand side of (1.2) is also the generating function for domino tilings of Aztec diamond of order $k$ by the number of horizontal dominoes, a celebrated result of Elkies, Kuperberg, Larsen and Propp [16].

Another conjecture in [23] concerns an interpretation for the refined powered Catalan numbers in terms of 120-avoiding inversion sequences. The integer sequence of powered Catalan numbers $\{p_n\}_{n \geq 1}$ is registered on [26] as A113227, whose first few terms are

$$ 1, 2, 6, 23, 105, 549, 3207, 20577, 143239, \ldots. $$

It is known that the pattern avoiding classes $\mathcal{S}_n(1234)$, $\mathcal{S}_n(1324)$, $\mathcal{S}_n(1342)$, $\mathcal{S}_n(1432)$, $\mathcal{I}_n(101)$ and $\mathcal{I}_n(110)$ are all counted by the powered Catalan number $p_n$ (see [8, 14, 25] and
the references cited therein). The number $p_n$ has a natural refinement by $p_n = \sum_{k=1}^{n} c_{n,k}$, where $c_{n,k}$ are defined recursively by

\begin{equation}
\begin{aligned}
c_{1,1} &= 1 \text{ and } c_{n,0} = 0, \text{ for } n \geq 1, \\
c_{n,k} &= c_{n-1,k-1} + k \sum_{j=k}^{n-1} c_{n-1,j}, \text{ for } n \geq 2 \text{ and } 1 \leq k \leq n.
\end{aligned}
\end{equation}

Corteel, Martinez, Savage and Weselcouch [14] proved that the cardinality of $I_n(101)$ or $I_n(110)$ is $p_n$ by showing

\begin{equation}
|\{e \in I_n(101) : \text{zero}(e) = k\}| = |\{e \in I_n(110) : \text{zero}(e) = k\}| = c_{n,k},
\end{equation}

where \text{zero}(e) is the number of zero entries of $e$. Lin and Yan [23] showed that $I_n(120)$ has cardinality $p_n$ by establishing a bijection between $\mathcal{G}_n(3214)$ and $I_n(120)$ but were unable to prove the following refinement.

**Conjecture 1.2** (Lin and Yan [23, Conj. 2.20]). For $n \geq 1$ and $1 \leq k \leq n$, we have

\begin{equation}
|\{e \in I_n(120) : \text{zero}(e) = k\}| = c_{n,k}.
\end{equation}

In this paper, we confirm the above two conjectures.

The rest of this paper is organized as follows. In Section 2, we prove Conjecture 1.1 by considering the last entries of $1\underline{20}$-avoiding ascent sequences. In Section 3, we prove Conjecture 1.2 via a well-designed algorithm for constructing $1\underline{20}$-avoiding inversion sequences. We will also consider the last entry statistic of $1\underline{20}$-avoiding inversion sequences, which leads to a new succession rule for the powered Catalan numbers. Finally, we end this paper with two tempting equidistribution conjectures concerning the open problem to enumerate $2\underline{34}$-avoiding permutations.

## 2. On $1\underline{20}$-avoiding ascent sequences

This section is devoted to the proof of Conjecture 1.1. We begin with a different characterization of $\mathcal{PA}_n(1\underline{20})$, which is more convenient for our enumerative purpose.

For a given $e \in \mathcal{PA}_n$, since it is primitive, each consecutive pair $(e_i, e_{i+1})$ forms either a descent, or an ascent. Now we can uniquely partition $e$ with "/", into maximal decreasing subsequences called runs. Let $t(e)$ be the subsequence formed by the least entry in each run of $e$, and we call it the tail sequence of $e$. For example,

\[ e = 0102324325 = 0/10/2/32/432/5 \quad \text{and} \quad t(e) = 002225. \]

We have the following characterization of $\mathcal{PA}_n(1\underline{20})$ using tail sequences.

**Lemma 2.1.** For any $e \in \mathcal{PA}_n$ with $\text{asc}(e) = k$, we have

\[ e \in \mathcal{PA}_n(1\underline{20}) \text{ if and only if } t(e) \in I_{k+1} \text{ is non-decreasing.} \]

**Proof.** Clearly, $t(e) \in I_{k+1}$ is a consequence of $\text{asc}(e) = k$ and the definitions of primitive ascent sequences and tail sequences. Now we show that $e$ contains a $1\underline{20}$ pattern if and only if $t(e) = t_1 t_2 \ldots t_{k+1}$ contains a descent.

Suppose the triple $e_i e_{i+1} e_j$ forms a $1\underline{20}$ pattern in $e$, then $e_i$ must be the tail of a run. Suppose $e_l$ is the tail of the run that contains $e_j$, for some $l \geq j$. We see $e_i > e_j \geq e_l$, hence
t(e), containing e_i and e_{i+1}, must have a descent. Conversely, suppose t_i > t_{i+1} is a descent in t(e), and suppose the tails of the i-th and (i + 1)-th runs, and the largest entry in the (i + 1)-th run in the original sequence e, are e_p (= t_i), e_q (= t_{i+1}) and e_{p+1} respectively. Then e_p e_{p+1} e_q forms a 120 pattern in e, which completes the proof of the lemma. □

Let PA denote the set of all primitive ascent sequences. For each e ∈ PA, define the weight of e by \[ \text{wt}(e) = \prod_{i=1}^{\text{len}(e)} \text{wt}(e_i), \] where
\[ \text{wt}(e_i) := \begin{cases} 1 & \text{if } e_i \text{ is a tail,} \\ x & \text{otherwise.} \end{cases} \]

If e has k ascents, then it has exactly k + 1 tails hence \[ \text{wt}(e) = x^{\text{len}(e) - k - 1}. \] Therefore, Eq. (1.2) can be rewritten as
\[ \sum_{e \in \mathcal{PA}_{k,i}(120)} \text{wt}(e) = (1 + x)^{\binom{k+1}{2}}, \] which is equivalent to Conjecture 1.1. In order to prove (2.1), we introduce the refined enumerator
\[ f_{k,i}(x) := \sum_{e \in \mathcal{PA}_{k,i}(120)} \text{wt}(e), \]
where \( \mathcal{PA}_{k,i}(120) \) is the set of all \( e \in \mathcal{PA}(120) \) with asc(e) = k and the last entry of e being i. We have the following recursion for \( f_{k,i}(x) \).

**Lemma 2.2.** For \( k \geq 0 \) and \( 0 \leq i \leq k + 1 \), we have the recursion
\[ f_{k+1,i}(x) = \sum_{j=0}^{i} (1 + x)^{k+1-i} f_{k,j}(x) - f_{k,i}(x) \]
with the initial conditions \( f_{0,0}(x) = 1 \), and \( f_{k,i}(x) = 0 \) for \( k < i \).

**Proof.** By the characterization in Lemma 2.1, each ascent sequence \( e \in \mathcal{PA}_{k+1,i}(120) \) with tail sequence \( t(e) = t_1 t_2 \cdots t_{k+2} \) and the penultimate tail being \( e_p = j \) (0 ≤ j ≤ i) is decomposed into
- the prefix \( e_1 e_2 \cdots e_p \in \mathcal{PA}_{k,j}(120) \),
- the entries \( e_{p+1} > e_{p+2} > \cdots > e_{\text{len}(e)-1} \) forming a subset of the interval \([i+1, k+1]\) with the restriction that such a subset must be non-empty whenever \( j = i \) (since \( e \) is primitive), and
- the last entry \( e_{\text{len}(e)} = i \).

Now if we take the weight into consideration, recursion (2.2) follows from the decomposition above immediately. □

We are now ready to prove the following expression for \( f_{k,i}(x) \).
Theorem 2.3. For $0 \leq i \leq k$, we have

\begin{equation}
(2.3) \quad f_{k,i}(x) = (1 + x)^{\binom{i}{2}} \prod_{\ell=i+1}^{k} \left( (1 + x)^{\ell} - 1 \right) .
\end{equation}

Conjecture 1.1 is an immediate consequence of Theorem 2.3.

Proof of Conjecture 1.1. It follows from recursion (2.2) and formula (2.3) that

\begin{equation}
\sum_{i=0}^{k} f_{k,i}(x) = f_{k+1,k+1}(x) = (1 + x)^{\binom{k+1}{2}},
\end{equation}

which establishes (2.1) and thus Conjecture 1.1 is true. \qed

We are going to prove Theorem 2.3 by induction based on recursion (2.2).

Proof of Theorem 2.3. We will prove the result by induction on $k$. The first few values $f_{0,0}(x) = 1$, $f_{1,0}(x) = x$ and $f_{1,1}(x) = 1$ can be readily checked. Suppose that (2.3) holds for all $k \leq m$ and $0 \leq i \leq k$, for certain integer $m \geq 1$. We compute the case with $k = m + 1$.

By recursion (2.2), we have

\[
f_{m+1,m+1}(x) = \sum_{i=0}^{m} f_{m,i}(x) = \sum_{i=0}^{m} (1 + x)^{\binom{i}{2}} \prod_{\ell=i+1}^{m} \left( (1 + x)^{\ell} - 1 \right) \\
= (1 + x)^{\binom{m}{2}} + (1 + x)^{m} \sum_{i=0}^{m-1} (1 + x)^{\binom{i}{2}} \prod_{\ell=i+1}^{m-1} ((1 + x)^{\ell} - 1) \\
= (1 + x)^{\binom{m}{2}} + (1 + x)^{m} \sum_{i=0}^{m-1} f_{m-1,i}(x) \\
= (1 + x)^{\binom{m}{2}} + (1 + x)^{m} (1 + x)^{\binom{m}{2}} \\
= (1 + x)^{\binom{m+1}{2}} .
\]

For $0 \leq i \leq m$, it follows from

\[
\sum_{i=0}^{k} f_{k,i}(x) = f_{k+1,k+1}(x) = (1 + x)^{\binom{k+1}{2}} \quad (1 \leq k \leq m)
\]

and recursion (2.2) that

\[
f_{m+1,i}(x) = \sum_{j=0}^{i} (1 + x)^{m+1-i} f_{m,j}(x) - f_{m,i}(x) \\
= (1 + x)^{m+1-i} \sum_{j=0}^{i} (1 + x)^{\binom{j}{2}} \prod_{\ell=j+1}^{m} \left( (1 + x)^{\ell} - 1 \right) - (1 + x)^{\binom{i}{2}} \prod_{\ell=i+1}^{m} \left( (1 + x)^{\ell} - 1 \right)
\]
\[
(1 + x)^{m+1 - \binom{i+1}{2}} \sum_{\ell=0}^{i} f_{i,\ell}(x) - 1 \right) (1 + x)^{i} \prod_{\ell=i+1}^{m} \left( (1 + x)^{\ell} - 1 \right) \\
= ((1 + x)^{m+1} - 1) (1 + x)^{i} \prod_{\ell=i+1}^{m} \left( (1 + x)^{\ell} - 1 \right) \\
= (1 + x)^{i} \prod_{\ell=i+1}^{m+1} \left( (1 + x)^{\ell} - 1 \right).
\]

Thus, we have verified the case with \( k = m + 1 \) for (2.3). The proof is now completed by induction. \( \square \)

3. On 120-avoiding inversion sequences

3.1. Proof of Conjecture 1.2. In this subsection, we develop a delicate algorithm to construct recursively 120-avoiding inversion sequences, which leads to a proof of Conjecture 1.2.

The following operations are quite standard (cf. [14]) for constructing new inversion sequences from old ones. For an inversion sequence \( e = e_1 e_2 \ldots e_n \in I_n \) and any integer \( t \), let

\[
\sigma_t(e) := e'_1 e'_2 \ldots e'_n, \text{ where } e'_i = \begin{cases} 
0 & \text{if } e_i = 0, \\
e_i + t & \text{otherwise.}
\end{cases}
\]

Note that the image \( \sigma_t(e) \) is not necessarily an inversion sequence. And sometimes we need to apply \( \sigma_t \) on substrings of an inversion sequence. We use concatenation to add an entry to the beginning or the end of an inversion sequence: \( 0 \cdot e \) is the inversion sequence \( 0 e_1 e_2 \ldots e_n \) and for \( 0 \leq i \leq n \), \( e \cdot i \) is the inversion sequence \( e_1 e_2 \ldots e_n i \). For any sequence \( s \), not necessarily an inversion sequence, we use \( \min(s) \) to denote the value of the smallest entry in \( s \).

Quite recently, Beaton, Bouvel, Guerrini and Rinaldi [8, Prop. 19] rephrased (1.3) in terms of the following succession rule, and reproved the statement of Corteel et al. for \( I_n(110) \) by explaining their growth subjected to this rule.

\[
\Omega_{p\text{Cat}} = \begin{cases}
(1) \\
(k) \rightsquigarrow (1), (2)^2, (3)^3, \ldots, (k)^k, (k + 1).
\end{cases}
\]

Here \( (i)^i \) means \( i \) copies of \( (i) \). The powered Catalan generating tree (actually an infinite rooted tree) can be constructed from \( \Omega_{p\text{Cat}} \) like this: the root is \( (1) \) and the children of a vertex labelled \( (k) \) are those generated according to the rule \( \Omega_{p\text{Cat}} \). Note that the number of vertices at level \( n \) that carry the label \( (k) \) in the powered Catalan generating tree is precisely the quantity \( c_{n,k} \).

Our strategy to prove Conjecture 1.2 is to show that the family \( \{ I_n(120) \}_{n \geq 1} \) also obeys the succession rule \( \Omega_{p\text{Cat}} \). We remark that the first step is the same as given in [8], while
the second step involving “Algorithm BS” is substantially different and crucial in dealing with 120-avoiding, rather than 110-avoiding inversion sequences.

**Proof of Conjecture 1.2.** For \(1 \leq k \leq n\), let \(I_{n,k}(120) := \{e \in I_n(120) : \text{zero}(e) = k\}\). Let \(e = e_1 \ldots e_n \in I_{n,k}(120)\) and suppose its \(k\) zero entries are indexed as \(e_{i_1}(= e_1), e_{i_2}, \ldots, e_{i_k}\). Since \(e\) is 120-avoiding, it uniquely decomposes as

\[
e = 0W_10W_20\ldots 0W_{k-1}0W_k,
\]

where for \(1 \leq j \leq k-1\), \(W_j\) is a non-increasing, zero-free substring of length \(i_{j+1} - i_j - 1\), and \(W_k\) is a 120-avoiding, zero-free substring of length \(n - i_k\).

**Step I:** Set \(e' = 0 \cdot \sigma_1(e) = 0e'_1 \ldots e'_n = 00\sigma_1(W_1)0\sigma_1(W_2)0\ldots 0\sigma_1(W_{k-1})0\sigma_1(W_k)\).

**Step II:** Transform \(e'\) into one or more 120-avoiding inversion sequences, according to the following three succession cases.

- **(k + 1):** Set \(e^{(k+1)} = e'\).
- **(1):** Replace each of \(e'_{i_1}, e'_{i_2}, \ldots, e'_{i_k}\) by 1, and denote the new sequence by \(e^{(1)}\).
- **(j):** For any \(2 \leq j \leq k\), replace each of \(e'_{i_{j+1}}, e'_{i_{j+2}}, \ldots, e'_{i_k}\) by 1. Choose one integer \(1 \leq m \leq j\), then go on to replace the zero \(e'_{i_m}\) by 1, and denote this new sequence by \(e''\). Apply the following Algorithm BS on \(e''\). The output sequence is denoted as \(e^{(j,m)}\).

---

### Algorithm BS (backward shift)

**Input sequence**

\[e = 00U_10 \ldots 0U_{m-1}1U_m0 \ldots 0U_j1U_{j+1} \ldots 1U_k,\]

where the substrings \(U_1, \ldots, U_k\) contain neither 0 nor 1, and the 1 between \(U_{m-1}\) and \(U_m\) is the only 1 to the left of \(U_j\).

If \(m = j\) or \(U_m = \emptyset\), output \(e\) as is. Note that in this case \(e\) contains at most one 1 between the 0s.

Otherwise, initiate \(R = U_m\) and we go through the following steps to locally transform certain substring of \(e\).

**Step 1** Find the substring \(L\delta R\), where \(\delta = 0\) or 1, and \(L\) is the maximal zero-free substring extended to the left of \(\delta\).

**Step 2** Transform \(L\delta R \rightarrow L \cdot \sigma_{-1}(R) \cdot \delta\).

**Step 3** If \(L \neq \emptyset\), put \(R = L\) and go back to Step 1.

Else if \(\min(\sigma_{-1}(R)) = 1\), terminates.

Else put \(R = \sigma_{-1}(R)\) and go back to Step 1.

**Output the final sequence.**

### Example 3.1.

Take \(e = 011100630870020 \in I_{15,7}(120)\) with \(j = 5\) and \(m = 3\) for example. Applying the succession rules (j) and the algorithm BS gives

\[e' = 0022200740980030 \rightarrow e'' = 0022201740980131 \rightarrow 0022206310980131\]
For well-definedness, one checks that following the succession rules \((k + 1), (1)\) and \((j)\), we end up respectively, with one sequence \(e^{(k+1)} \in I_{n+1,k+1}(\underline{120})\), one sequence \(e^{(1)} \in I_{n+1,1}(\underline{120})\), and \(j\) sequences \(e^{(j,m)} \in I_{n+1,j}(\underline{120})\) for \(1 \leq m \leq j\) and \(2 \leq j \leq k\).

To complete the proof, we have to show that if we apply the above process for each sequence in \(I_n(\underline{120})\), we generate every sequence in \(I_{n+1}(\underline{120})\) precisely once. The first thing to notice is that \(e^{(k+1)}\) contains no 1s, \(e^{(1)}\) has only one 0, and \(e^{(j,m)}\) has at least two 0s and at least one 1. So these three cases are mutually exclusive. It should be clear how to invert \(e^{(k+1)}\) or \(e^{(1)}\) to recover \(e\), so it suffices to invert \(e^{(j,m)}\). This is done by first applying the forward shift algorithm below to \(e^{(j,m)}\), which outputs the sequence \(e''\); then obtaining \(e'\) from \(e''\) by replacing all 1s by 0s; and finally deriving \(e\) from \(\sigma_{-1}(e') = 0 \cdot e\).

**Algorithm FS** (forward shift)

Input sequence \(e\), which has at least two 0s and at least one 1. We call the substring inbetween the leftmost 0 and the rightmost 0 the zero zone of \(e\). If \(e\) has less than two 1s in the zero zone, output \(e\) as is.

Otherwise we can write
\[
e = 0 \ldots 0V_110V_{i+1}0 \ldots 0V_j10 \ldots 0V_l,
\]
where the substrings \(V_1, \ldots, V_j, V_{j+1}, \ldots, V_{l-1}\) are zero-free and non-increasing, \(V_i\) is zero-free and \(\underline{120}\)-avoiding, and \(V_i1\) (resp. \(V_j1\)) contains the leftmost (resp. rightmost) 1 in the zero zone. Now initiate \(L = V_1\) and we go through the following steps to locally transform certain substring of \(e\).

1. **Step 1** Find the substring \(L0R\), where \(R\) is the maximal zero-free substring extended to the right of 0.

2. **Step 2** Transform \(L0R \rightarrow 0 \cdot \sigma_1(L) \cdot R\).

3. **Step 3** If \(R = R'1\) ends with the rightmost 1 in the zero zone, continue.
   - If \(R' = \emptyset\), transform \(\sigma_1(L)10 \rightarrow 1 \cdot \sigma_2(L) \cdot 0\) and terminates.
   - Else transform \(R'10 \rightarrow 1 \cdot \sigma_1(R') \cdot 0\) and terminates.

   Else if \(R = \emptyset\), put \(L = \sigma_1(L)\) and go back to Step 1.
   - Else put \(L = R\) and go back to Step 1.

Output the final sequence.

**Example 3.2.** Take \(e = 0111052010980131 \in I_{16,5}(\underline{120})\) for example. Applying the algorithm FS gives
\[
e \rightarrow 0022252010980131 \rightarrow 0022206310980131 \rightarrow 0022201740980131 = e''.
\]
In conclusion, we have proved that 120-avoiding inversion sequences grow according to the rule $\Omega_{pCat}$ if every sequence with $k$ zeros is represented by $(k)$. This completes the proof of the conjecture. □

Example 3.3. In this example, we find all $1 + 1 + 2 + 3 + 4 = 11$ images of an inversion sequence $e \in I_{120}$, following the steps described in the proof above.

$$e = 010211002565 \quad \mapsto \quad e^{(4+1)} = 0020322003676.$$  
$e = 010211002565 \quad \mapsto \quad e^{(1)} = 0121322113676.$  
$e = 010211002565 \quad \mapsto \quad \begin{cases} e^{(2,2)} = 0021322113676, \\ e^{(2,1)} = 0110322113676. \end{cases}$  
$e = 010211002565 \quad \mapsto \quad \begin{cases} e^{(3,3)} = 0020322113676, \\ e^{(3,2)} = 0102111013676, \\ e^{(3,1)} = 0110322013676. \end{cases}$  
$e = 010211002565 \quad \mapsto \quad \begin{cases} e^{(4,4)} = 0020322013676, \\ e^{(4,3)} = 0020322103676, \\ e^{(4,2)} = 0102111003676, \\ e^{(4,1)} = 0110322003676. \end{cases}$

3.2. The last entry statistic. In this subsection, we study the last entry statistic of inversion sequences and obtain a new succession rule for powered Catalan numbers. For an inversion sequence $e \in I_n$, let $\text{last}(e) = e_n$ be the last entry of $e$. The last entry statistic has been found to be useful in solving two enumeration conjectures in [19]. By comparing the construction of the rule $\Omega_{pCat}$ for 120-avoiding inversion sequences in the proof of Conj. 1.2 and that for 110-avoiding inversion sequences in the proof of [8, Prop. 19], we have the following equidistribution.

**Proposition 3.4.** The triple $(\text{last, zero, rmin})$ has the same distribution over $I_n(120)$ and $I_n(110)$, where $\text{rmin}(e)$ is the number of right-to-left minima of an inversion sequence $e$.

Lin and Yan [23, Lem. 2.19] showed that Baril and Vajnovszki’s $b$-code [5] restricts to a bijection between $\mathcal{S}_n(3214)$ and $I_n(120)$. For a permutation $\pi = \pi_1\pi_2\cdots\pi_n \in \mathcal{S}_n$, define the encoding $\Theta$ by

$$\Theta(\pi) = (e_1, e_2, \ldots, e_n), \quad \text{where } e_i := |\{j : j < i \text{ and } \pi_j > \pi_i\}|.$$  
The encoding $\Theta$, known as $\text{invcode}$ of permutations, is a variation of the famous Lehmer code. One interesting feature of $\Theta$ that the $b$-code does not possess is $\text{last}(\pi) = \text{last}(\Theta(\pi))$, where $\text{last}(\pi) := n - \pi_n$.

**Proposition 3.5.** The $\text{invcode}$ $\Theta$ restricts to a bijection between $\mathcal{S}_n(3214)$ and $I_n(120)$. Consequently, the triple $(\text{last, zero, rmin})$ over $I_n(120)$ (or $I_n(110)$) is equidistributed with $(\text{last, lmax, rmax})$ over $\mathcal{S}_n(3214)$, where $\text{lmax}(\pi)$ (resp. $\text{rmax}(\pi)$) denotes the number of left-to-right maxima (resp. right-to-left maxima) of a permutation $\pi$.  

Proof. Let \( \pi \in \mathfrak{S}_n \) and \( e = \Theta(\pi) \). If \( \pi \) contains the pattern 3214, then there exists \( 1 \leq i < j < k - 1 \leq n - 1 \) such that \( \pi_k > \pi_i > \pi_j > \pi_{j+1} \) and \( \pi_\ell < \pi_i \) for each \( j+1 < \ell < k \). Thus, we have \( e_k < e_j < e_{j+1} \) and so \( e_j e_{j+1} e_k \) forms a 120 pattern in \( e \). Conversely, suppose that \( 1 \leq i < j - 1 \) and \( e_i e_{i+1} e_j \) is a 120 pattern of \( e \). Since \( e_i > e_j \), we have \( \pi_i < \pi_j \) and there exists \( 1 \leq k < i \) such that \( \pi_i < \pi_k < \pi_j \). Now \( \pi_k \pi_i \pi_{i+1} \pi_j \) forms a pattern 3214 in \( \pi \). This completes the proof. \( \square \)

In [8, Prop. 25], Beaton, Bouvel, Guerrini and Rinaldi obtained another succession rule for the powered Catalan numbers, which is essentially different from \( \Omega_{p\text{Cat}} \):

\[
\Omega_{1214} = \begin{cases} 
(1,1) \\
(1,q) \mapsto (1,q+1),(2,q),\ldots,(1+q,1), \\
(p,q) \mapsto (1,p+q),(2,p+q-1),\ldots,(p,q+1), \\
(p+1,0),\ldots,(p+q,0), \quad & \text{if } p > 1.
\end{cases}
\]

The consideration of the last entry statistic on 120-avoiding inversion sequences leads to a third succession rule for the powered Catalan numbers.

For a sequence \( e \in \mathbf{I}_n(120) \), let us introduce the parameters \( (p,q) \) of \( e \) by

\[
p := | \{ k : (e_1,e_2,\ldots,e_n,k) \in \mathbf{I}_{n+1}(120) \text{ and } k > e_n \} | = n - e_n
\]

and

\[
q := | \{ k : (e_1,e_2,\ldots,e_n,k) \in \mathbf{I}_{n+1}(120) \text{ and } k \leq e_n \} |.
\]

**Proposition 3.6.** The \( \mathbf{I}_n(120) \)-avoiding inversion sequences grow according to the following succession rule

\[
\Omega_{120} = \begin{cases} 
(1,1) \\
(p,q) \mapsto (p,2),(p-1,3),\ldots,(1,p+1), \\
(p+1,q),(p+2,q-1),\ldots,(p+q,1).
\end{cases}
\]

Proof. Let \( e \) be a sequence in \( \mathbf{I}_n(120) \) with parameters \( (p,q) \). It is clear that the sequence \( s := (e_1,e_2,\ldots,e_n,k) \) is in \( \mathbf{I}_{n+1}(120) \) if and only if \( n \geq k \geq e_n - q + 1 \), where \( e_n - q + 1 \) equals the largest ascent bottom of \( e \). We consider two cases:

- If \( e_n - k \leq n \), then \( e_n k \) forms an ascent of \( f \) whose ascent bottom \( e_n \) is obviously not smaller than \( e_n - q + 1 \). So if we write \( k = e_n + i \) for some \( 1 \leq i \leq n - e_n = p \), then the parameters of \( f \) are \( (p-i+1,i+1) \).
- If \( e_n - q + 1 \leq k \leq e_n \), then \( k = e_n + 1 - i \) for some \( 1 \leq i \leq q \). In this case, the parameters of \( f \) are \( (p+i,q+1-i) \).

Summing over all the above two cases results in the succession rule \( \Omega_{120} \). \( \square \)

4. Two equidistribution conjectures

The classification of Wilf equivalences for vincular patterns of length 3 in inversion sequences has been completed, thanks to Auli and Elizalde’s recent work\(^1\) [3]. Towards the

\(^1\)Auli and Elizalde independently initiated their work, we thank them for keeping us informed.
complete classification of vincular patterns of length 4 in permutations, Baxter and Shattuck conjectured [7] that \( \mathcal{S}_n(2314) \) has cardinality \( p_n \), the \( n \)-th powered Catalan number. In their attempt to prove this conjecture, Beaton, Bouvel, Guerrini and Rinaldi [8, Conj. 23] found the following refinement.

**Conjecture 4.1.** The number of permutations of \( \mathcal{S}_n(2314) \) with \( k \) right-to-left minima is \( c_{n,k} \).

Conjecture 4.1 is equivalent to the assertion that the statistic ‘zero’ over \( I_n(120) \) or \( I_n(110) \) has the same distribution as ‘rmin’ over \( \mathcal{S}_n(2314) \), where \( \text{rmin}(\pi) \) denotes the number of right-to-left minima of a permutation \( \pi \). Using Maple program, we find the following refinement of Conjecture 4.1.

**Conjecture 4.2.** The quadruple \((\text{rmin}, \text{lmin}, \text{rmax}, \text{asc})\) on \( \mathcal{S}_n(2314) \) has the same distribution as \((\text{zero}, \text{max}, \text{rmin}, \text{rep})\) on \( I_n(110) \).

Here we use \( \text{lmin}(\pi) \) (resp. \( \text{asc}(\pi) \)) to denote the number of left-to-right minima (resp. ascents) of a permutation \( \pi \). And for an inversion sequence \( e \in I_n \), the two statistics involved are
\[
\text{max}(e) := |\{i \in [n] : e_i = i - 1\}| \quad \text{and} \quad \text{rep}(e) := n - |\{e_1, e_2, \ldots, e_n\}|.
\]

Conjecture 4.2 has been verified for \( 1 \leq n \leq 9 \).

Finally, the consideration of the last entry statistic leads to another refinement of Baxter and Shattuck’s enumeration conjecture.

**Conjecture 4.3.** The pair \((\text{last}, \text{rmax})\) on \( \mathcal{S}_n(2314) \) has the same distribution as \((\text{last}, \text{rmin})\) on \( I_n(120) \).

Conjecture 4.3 has also been verified for \( 1 \leq n \leq 9 \). In view of Proposition 3.6, it would be interesting to show that 2314-avoiding permutations grow according to the rule \( \Omega_{120} \).

One remarkable special case of Conjecture 4.3 is that
\[
|\{\pi \in \mathcal{S}_n(2314) : \pi_n = n\}| = B_{n-1} = |\{e \in I_n(120) : e_n = 0\}|,
\]
which follows from the enumeration results in [13,23]. Here \( B_n \) is the \( n \)-th Bell number.

**ACKNOWLEDGEMENT**

This work was initiated in the summer of 2019, when both authors were visiting the Research Center for Mathematics and Interdisciplinary Sciences at Shandong University. They would like to thank the center for the excellent working condition and the hospitality extended during their stay. The first named author was supported by the National Science Foundation of China grant 11871247 and the project of Qilu Young Scholars of Shandong University.
