Abstract: In this paper, we propose a novel kinematic and inverse dynamic model for the flybar-less (FBL) swashplate mechanism of a small-scale unmanned helicopter. The swashplate mechanism is an essential configuration of helicopter flight control systems. It is a complex, multi-loop chain mechanism that controls the main rotor. In recent years, the demand for compact swashplate designs has increased owing to the development of small-scale helicopters. The swashplate mechanism proposed in this paper is the latest architectures used for hingeless rotors without a Bell-Hiller mixer. Firstly, the kinematic analysis is derived from the parallel manipulators concepts. Then, based on the principle of virtual work, a methodology for deriving a closed-form dynamic equation of the FBL swashplate mechanism is developed. Finally, the correctness and efficiency of the presented analytical model are demonstrated by numerical examples and the influence factors of the loads acted on actuators are discussed.

Keywords: swashplate mechanism; helicopter; kinematics; inverse dynamics; load analysis

1. Introduction

The swashplate mechanism is a complex parallel manipulator steering control mechanism used in almost all helicopters [1,2]. The swashplate mechanism is a complex nonlinear system, and the most important component of the control system. It typically has three degrees of freedom (DOF) that produce pitch, heave, and roll motions. These three controls determine the pitch angles of the main rotor blades, and control the flight attitude of the helicopter [3].

Lange et al. performed a comprehensive kinematic model of the swashplate used in a CL-327 Guardian unmanned helicopter [4]. The kinematic formulation is derived within the framework of the forward and inverse kinematics of parallel robotic manipulators. Furthermore, the method of the natural orthogonal complement (NOC) [5] is employed to complete the dynamic analysis of this mechanism with the derivation of the equations of motion free of constraint wrenches [6]. Sabaapour and Zohoor completed another systematic research about the swashplate mechanism with a Bell-Hiller mixer, which is widely used in small-scale helicopters [7]. The dynamic analysis in [8] is based on the principle of virtual work and the concept of link Jacobian matrices [9]. Moreover, a fast inverse kinematic solution for a four-point swashplate mechanism was completed by Khaligh et al. [10]. Additionally, a simplified kinematic analysis based on using homogenous transformation and spatial configuration of the connecting linkages was presented by Saffarian and Fahimi [11]. Although modeling such a
mechanism has been discussed well in the above papers, the dynamics of a swashplate mechanism is still lacking in the literature. Additionally, there is a lack of investigation of a simplified model without the stabilizer flybar. The swashplate mechanism is usually equipped with a Bell-Hiller mixer [12] to improve the cyclic stability and make the cyclic control much more manageable. The effect of the flybar flapping angle is considered to be a key configuration of the blades pitch angle, which contributes greatly to the complexity of the dynamic modeling process. Additionally, a kinematic analysis of the Bell-Hiller mixer is difficult. The dialytic elimination method was used in [7], and resulted in a 48th-order polynomial which was too complex for real-time calculating. Although the Sylvester-Type Elimination method presented in [10] is more efficient, the method requires a certain amount of computations. Moreover, the flybar-less (FBL) swashplate mechanism is less complex in structure and lighter in weight. Another advantage of such an FBL rotor is that the inputs from the swashplate go directly to the main rotor blades for a fast and direct response [13]. Therefore, for many of the latest small-scale helicopters with higher maneuverability, the stabilizer flybar has been replaced by the electronic stabilization systems [14,15].

It should be noted that although the proposed FBL swashplate mechanism without the Bell-Hiller mixer is simpler than the traditional configuration, the whole mechanism is still a multi-loop mechanism chain with multiple DOF and complex topological configuration. In the kinematic analysis, it is crucial to derive a compact and precise inverse kinematic method to calculate the actuator inputs for real-time control applications. At the same time, the velocity analysis and acceleration analysis are essential for the dynamic analysis. Additionally, the kinematic model is important for the optimization of the swashplate mechanism [10].

The dynamic analysis of swashplate mechanism is complicated by the existence of two layers of parallel configuration with multiple closed-loop chains [16]. There are three well-known approaches to solve the dynamic problems for the real-time control of such a parallel manipulator [17]: the Newton-Euler formulation [18,19], the Lagrangian formulation [20,21], and the principle of virtual work [22,23]. The Newton-Euler method requires the motion equations to be written for each component, which leads to a large number of equations; it is a difficult task to eliminate the joint reactions economically. Thus, this method is not useful for the control system development. The Lagrangian formulation requires the derivatives of the kinetic energy of the whole mechanism, which is very complex in terms of a set of independent generalized coordinates. Other approaches have also been suggested [24–27]. The principle of virtual work is the most efficient method [28] for the dynamic analysis of parallel manipulators which allows the elimination of the constraint forces and moments at motion equations.

In this paper, the particular FBL swashplate mechanism is split into two submodules. A complete and precise kinematic model is derived by breaking each loop at a certain point and express the position of a selected point from two open chains that form the loop together with respect to a fixed framework. The nonlinear inverse kinematic relationship between the main rotor and swashplate mechanism is solved with specific spatial positioning of the rotating blades. We also derive the Jacobian matrices of each component. The principle of virtual work is employed to solve the inverse dynamics of the swashplate mechanism. The corresponding dynamic formulation is presented in closed form. The dynamic model provides a useful tool for the actuators’ load analysis.

The remainder of this paper is organized as follows: in Section 2, the mechanical model of the FBL swashplate mechanism is described. The kinematic analysis is done, including the position, velocity, and acceleration analysis. The complete inverse dynamic model of the FBL swashplate mechanism is derived. In Section 3, we prove the correctness of the whole model by comparing the calculated results with the simulation results, after which the load analysis of the actuators is performed. In Section 4, we conclude the work.
2. Methods

2.1. Mechanical Model

The FBL swashplate mechanism of a small-scale helicopter is shown in Figure 1a. A simplified mechanical model without drag arm is shown in Figure 1b. The whole mechanism is split into two parts: the Non-Rotating submodule (NR-SM) and the Rotating submodule (R-SM). The NR-SM is actually a 3-DOF motion platform. Thus, the attitude of the swashplate can be determined by three parameters: pitch, roll, and heave. The three actuators are fixed on the platform of the helicopter body and connected to the Non-Rotating part of the swashplate in a 120° arrangement through lower rods and input rockers. The swashplate is located on the main rotor shaft through the swashplate ball bearing, which is a combination of spherical and cylindrical joints. The cylindrical components allow a sliding motion (collective control, heave) along the axis of the main shaft as well as a rotation around the shaft. The spherical components enable the swashplate to rotate about two axes in its plane (cyclic controls, pitch and roll).

![Diagram of the swashplate mechanism](image)

**Figure 1.** (a) Principle prototype of the flybar-less swashplate mechanism assembled on a platform; (b) schematic of the proposed swashplate mechanism with the essential joints.

The rotating part of the swashplate is located on the non-rotating part through a revolute. The two main blades are connected to the rotating part with blade holders and upper rods. Each main blade is
mounted to the hub by means of a revolute joint. The whole R-SM is allowed to rotate with the main rotor shaft. The R-SM is greatly simplified without the Bell-Hiller mixer. The main blades have a more direct response to the actuators’ inputs.

2.2. Kinematic Analysis

Each submodule is analyzed separately with the concept of parallel manipulators. These two submodules can be related by the kinematic relationship between the two parts of the swashplate.

2.2.1. Inverse Kinematic Analysis

For the NR-SM, the output attitude of the swashplate can be obtained through the actuators. Orientations $\sigma_X$ and $\sigma_Z$, and the displacement $h$ of the swashplate, correspond to input actuator angles $\varphi_1$, $\varphi_2$, and $\varphi_3$, respectively (Figure 2), calculated using the inverse kinematic equations.

![Figure 2. Kinematic relationship of the swashplate mechanism.](image)

The kinematic relationship of the swashplate mechanism is illustrated in Figure 2. The original coordinate system is given by $O_0X_0Y_0Z_0$. A global frame $OXYZ$ is introduced at the center of the swashplate, while its Y axis coincides with the rotating axis of the shaft and the $OXY$ parallels to platform’s base plate. The direction $O_0Y_0$ coincides with the swashplate axis and the direction of $O_0X_0$ points to $A_1$. A local coordinate frame, $A_iX_iY_iZ_i$, is attached to each limb such that its origin is located at point $A_i$. $B_i$ and $C_i$ represent the center of the corresponding joint. The origin of the moving coordinate system $OX_5Y_5Z_5$ is $O$, which is the center of the swashplate plane. The positive direction of $OY_5$ is the direction of the normal vector with respect to the upper surface of the swashplate, and the direction of $OX_5$ points to $B_1$. $OX_5Y_5Z_5$ and $OX_4Y_4Z_4$ are the same in the initial state. The angle between $O_0X_0$ and $OX_5$ is $\sigma_2$. The angle between the intersecting line (plane $O_0Y_0Z_0$ and the swashplate) and $O_0Z_0$ is $\sigma_X$. The radius of the swashplate is $r$. $H$ is the distance between the center of the initial position of swashplate and the platform.

The attitude of the swashplate is characterized by three variables: $\sigma_X$, $\sigma_Z$, and $h$. The Euler angles $\alpha$ and $\beta$ are used instead of $\sigma_X$ and $\sigma_Z$ for expressing the transformation from the initial position to a certain attitude. First, the linear displacement of the swashplate along $O_0Y_0$ is denoted by $h$ ($T^h_Y$ is obtained). Second, a rotation of $\alpha$ degrees along the Z axis gives $R_Z(\alpha)$. Lastly, the swashplate rotates $\beta$ degrees along the X axis and $R_X(\beta)$ is obtained. The augmented rotation and transformation matrices are given by:
\[
R_X(\beta) = \begin{bmatrix}
1 & 0 & 0 & 0 \\
0 & \cos \beta & \sin \beta & 0 \\
0 & -\sin \beta & \cos \beta & 0 \\
0 & 0 & 0 & 1
\end{bmatrix},
R_Z(\alpha) = \begin{bmatrix}
\cos \alpha & \sin \alpha & 0 & 0 \\
-\sin \alpha & \cos \alpha & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1
\end{bmatrix},
T_Y^h = \begin{bmatrix}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & h & 0 & 1
\end{bmatrix}
\]

(1)

The coordinates of \( A_i \) in \( O_0X_0Y_0Z_0 \) can be expressed in matrix form as:
\[
A^0 = \begin{bmatrix}
A^0_0 \\
A^0_1 \\
A^0_2 \\
A^0_3
\end{bmatrix} = \begin{bmatrix}
L + r & 0 & 0 & 1 \\
L - r \sin 30^\circ & r \cos 30^\circ & 0 & 1 \\
L - r \sin 30^\circ & -r \cos 30^\circ & 0 & 1
\end{bmatrix}
\]

(2)

At any moment, the coordinates of \( B_i \) in \( OX_5Y_5Z_5 \) can be expressed in matrix form as:
\[
B^5 = \begin{bmatrix}
B^5_0 \\
B^5_1 \\
B^5_2 \\
B^5_3
\end{bmatrix} = \begin{bmatrix}
r & 0 & 0 & 1 \\
-r \sin 30^\circ & r \cos 30^\circ & 0 & 1 \\
-r \sin 30^\circ & -r \cos 30^\circ & 0 & 1
\end{bmatrix}
\]

(3)

With \( O_0X_0Y_0Z_0 \):
\[
B^0 = B^5 C^0_5
\]

(4)

where \( C^0_5 = T^h_Y, C^1_5 = R_X(\beta)R_Z(\alpha)T^h_Y, C^0_5 = C^4_5 C^0_4 = R_X(\beta)R_Z(\alpha)T^h_Y \); \( C^j_5 \) represents the coordinate transformation from \( O_0X_0Y_0Z_0 \) to \( O_jX_jY_jZ_j \). Thus:
\[
B^0 = B^5 C^0_5 = \begin{bmatrix}
\beta_{1,x}^0 & \beta_{1,y}^0 & \beta_{1,z}^0 & 1 \\
\beta_{2,x}^0 & \beta_{2,y}^0 & \beta_{2,z}^0 & 1 \\
\beta_{3,x}^0 & \beta_{3,y}^0 & \beta_{3,z}^0 & 1
\end{bmatrix}
\]

(5)

Additionally:
\[
A^0 = \begin{bmatrix}
A^0_0 \\
A^0_1 \\
A^0_2 \\
A^0_3
\end{bmatrix} = \begin{bmatrix}
a_{1,x}^0 & a_{1,y}^0 & a_{1,z}^0 & 1 \\
a_{2,x}^0 & a_{2,y}^0 & a_{2,z}^0 & 1 \\
a_{3,x}^0 & a_{3,y}^0 & a_{3,z}^0 & 1
\end{bmatrix}
\]

(6)

where \( \varphi_1 \) can be solved in the \( A_1C_1B_1O \) loop:
\[
\varphi_1 = \eta - \gamma
\]

(7)

where:
\[
\gamma = \arccos \left( \frac{L^2 + l_{A_1B_1}^2 - b_{A_1C_1}^2}{2L_{A_1B_1}} \right)
\]

The spatial relationships among coordinates are as shown in Figure 2. The transfer matrix is given by:
\[
C^2_0 = T_Z - r \cos 30^\circ - T_X^L - r \sin 30^\circ, C^3_0 = T_Z^r - r \cos 30^\circ - T_X^L + r \sin 30^\circ
\]

(8)

Hence:
\[
\begin{cases}
B^2_2 = B^5_2 C^0_2 = \begin{bmatrix}
\beta_{2,x}^0 & L + r \sin 30^\circ & \beta_{2,y}^0 & \beta_{2,z}^0 - r \cos 30^\circ & 1
\end{bmatrix}
\end{cases}
\]

(9)
The linear distance between $C_i$ and $B_i$ is $l_{B_iC_i}$, which can be converted into spatial coordinates as follows:

$$\sqrt{(b'_{l,x} + L \cos \varphi_i)^2 + (b'_{l,y} - L \sin \varphi_i)^2 + (b'_{l,z})^2} = l_{B_iC_i} \tag{10}$$

Expanding and rearranging Equation (10) results in:

$$\frac{l_{B_iC_i}^2 - L^2 - (b'_{l,x})^2 - (b'_{l,y})^2 - (b'_{l,z})^2}{2L \sqrt{(b'_{l,x})^2 + (b'_{l,y})^2}} = \frac{b'_{l,x}}{\sqrt{(b'_{l,x})^2 + (b'_{l,y})^2}} \cos \varphi_i - \frac{b'_{l,y}}{\sqrt{(b'_{l,x})^2 + (b'_{l,y})^2}} \sin \varphi_i \tag{11}$$

The inverse kinematic solution of $\varphi_i$, for $i = 2, 3$, is given by:

$$\varphi_i = \theta_i - \tau_i \tag{12}$$

where:

$$\tau_i = \arcsin \frac{l_{B_iC_i}^2 - L^2 - (b'_{l,x})^2 - (b'_{l,y})^2 - (b'_{l,z})^2}{2L \sqrt{(b'_{l,x})^2 + (b'_{l,y})^2}}, \quad \theta_i = \arcsin \frac{b'_{l,x}}{\sqrt{(b'_{l,x})^2 + (b'_{l,y})^2}} \tag{13}$$

Note that the IK solutions of $\varphi_1$, $\varphi_2$, and $\varphi_3$ calculated in Equations (7) and (12) contain the Euler angles $\alpha$ and $\beta$, which are equal to the tilt angles of the swashplate $\sigma_X$ and $\sigma_Z$ in special cases.

As shown in Figures 2 and 3, we now have the $OX_0'Y_0'Z_0'$ coordinate. There is an intersecting line between the rotor and tilt planes. The angle between the intersecting line and $OX_0'$ is $\varphi_1$. The normal unit vectors of the rotor and tilt planes are defined as:

$$\begin{bmatrix} n_1 \\ n_2 \end{bmatrix} = \begin{bmatrix} \sin \theta_i & 0 & \cos \theta_i \\ 0 & 1 & 0 \end{bmatrix} \begin{bmatrix} \cos \alpha & \sin \alpha & 0 \\ -\cos \beta \sin \alpha & \cos \beta \cos \alpha & \sin \beta \\ \sin \beta \sin \alpha & -\sin \beta \cos \alpha & \cos \beta \end{bmatrix} = \begin{bmatrix} -\cos \beta \sin \alpha & \cos \beta \cos \alpha & \sin \beta \\ \sin \beta \sin \alpha & -\sin \beta \cos \alpha & \cos \beta \end{bmatrix} \tag{13}$$

Figure 3. Kinematic relationship between the tilt plane and the rotor plane.
The direction vector of the intersecting line is given by $S_{\text{int}}$:

\[
S_{\text{int}} = n_1 \times n_2
\]

\[
= \begin{vmatrix}
  i & j & k \\
  -\cos \beta \sin \alpha & \cos \beta \cos \alpha & \sin \beta \\
  \sin \theta_1 & 0 & \cos \theta_1 \\
\end{vmatrix}
\]

\[
= (\cos \theta_1 \cos \beta \cos \alpha)i - (\cos \theta_1 \cos \beta \sin \alpha - \sin \theta_1 \sin \beta)j + (\sin \theta_1 \cos \beta \cos \alpha)k
\]

\[
= \begin{bmatrix}
  \cos \theta_1 \cos \beta \cos \alpha \\
  \cos \theta_1 \cos \beta \sin \alpha + \sin \theta_1 \sin \beta \\
  -\sin \theta_1 \cos \beta \cos \alpha \\
\end{bmatrix}
\]  

The direction vector of $OX'_0$ is defined as $S_{OX'_0}$:

\[
S_{OX'_0} = \begin{bmatrix}
  \cos \theta_1 \\
  -\sin \theta_1 \\
\end{bmatrix}
\]  

Therefore, $\phi_t$ is given by:

\[
\tan(\phi_t) = \frac{S_{OX'_0} \times S_{\text{int}}}{S_{OX'_0} \cdot S_{\text{int}}}
\]

\[
= \frac{\cos \theta_1 \cos \beta \sin \alpha + \sin \theta_1 \sin \beta}{\cos \beta \cos \alpha}
\]  

Thus:

\[
\phi_t(\theta_t) = \arctan \frac{\cos \theta_1 \cos \beta \sin \alpha + \sin \theta_1 \sin \beta}{\cos \beta \cos \alpha}
\]  

Note that $\phi_t$ is equal to $\sigma_Z$ when $\theta_t = 0^\circ$; thus, Equation (17) results in:

\[
\phi_t(0^\circ) = \sigma_Z = \alpha
\]  

Substituting $\theta_t = 270^\circ$ into Equation (17), we have:

\[
\phi_t(270^\circ) = \sigma_X = \arctan \frac{-\sin \beta}{\cos \beta \sin \alpha}
\]

Combining Equations (18) and (19) yields:

\[
\alpha = \sigma_Z, \beta = \arctan(-\tan \sigma_X \cos \sigma_Z)
\]

In this work, $\phi_t$ was used to relate the R-SM and NR-SM. For the NR-SM, the corresponding $\sigma'_Z$ equals $\phi_t$. Thus:

\[
\alpha' = \sigma'_Z = \arctan \frac{\cos \theta_1 \cos \beta \sin \alpha + \sin \theta_1 \sin \beta}{\cos \beta \cos \alpha}
\]

\[
\sigma'_X = \phi_t(\theta_t + 270^\circ) = \arctan \frac{\sin \theta_1 \cos \beta \sin \alpha - \cos \theta_1 \sin \beta}{\cos \beta \cos \alpha}
\]

Therefore:

\[
\beta' = \arctan(-\tan \sigma'_X \cos \sigma'_Z)
\]

\[
= \arctan \left( \cos \alpha' \frac{\cos \theta_1 \sin \beta - \sin \theta_1 \cos \beta \sin \alpha}{\cos \beta \cos \alpha} \right)
\]

The transformation matrix of the R-SM with respect to the local frame of the NR-SM is:

\[
C_6^f = R_\beta(\beta')R_\alpha(\alpha')R_\gamma(\theta_t)
\]
The purpose of the inverse kinematics of the NR-SM is determining the pose of the swashplate, i.e., \( \sigma_Z, \sigma_X, \) and \( h \). However, for a precise \( \theta_i \), only one set of pitch angles \( \{ \theta_{b1}, \theta_{b2} \}_i \) is known. Thus, at least two sets of pitch angles are necessary.

The kinematic relationship of NR-SM consists of two symmetrical parts. As shown in Figure 4, the blade1 side is presented; the blade2 side is simply mirrored in frame \( X'_0Y'_0Z'_0 \). Referring to Figure 4, the length of \( ED \) can be written as:

\[
I_{E_iD_1}^2 = (x_{D_1}^0 - x_{E_1}^0)^2 + (y_{D_1}^0 - y_{E_1}^0)^2
\]

where \( x_{D_1}^0 = r_R \cos \varphi_t, y_{D_1}^0 = r_R \sin \varphi_t + h, x_{E_1}^0 = L_R \cos \theta_{b1}, y_{E_1}^0 = L_R \sin \theta_{b1} + H_R \).

Figure 4. Kinematic relationship of the Rotating submodule (R-SM).

For \( \theta_t = 0^\circ \) and \( \theta_t = 270^\circ \), the corresponding pitch angles are \( \{ \theta_{b11}, \theta_{b12} \}_{\theta_t=0^\circ} \) and \( \{ \theta_{b21}, \theta_{b22} \}_{\theta_t=270^\circ} \) (cyclic pitch inputs). Substituting these pitch angles into Equation (24) gives:

\[
\begin{align*}
\lambda_{E_iD_1}^2 &= (\cos \sigma_Z + \mu_{11})^2 + (\sin \sigma_Z + \lambda_{11})^2 \\
\lambda_{E_iD_1}^2 &= (\cos \sigma_Z + \mu_{12})^2 + (\sin \sigma_Z + \lambda_{12})^2 \\
\lambda_{E_iD_1}^2 &= (\cos \sigma_X + \mu_{21})^2 + (\sin \sigma_X + \lambda_{21})^2 \\
\lambda_{E_iD_1}^2 &= (\cos \sigma_X + \mu_{22})^2 + (\sin \sigma_X + \lambda_{22})^2
\end{align*}
\]

where:

\[
\lambda_{ij} = -L_R \sin \theta_{bij} + h - H_R \\
\hat{\lambda}_{E_iD_1} = \frac{I_{E_iD_1}}{r_R}, \hat{\mu}_{ij} = -\frac{L_R \cos \theta_{bij}}{r_R}
\]

where \( \sigma_Z, \sigma_X, \) and \( h \) in Equation (25) can be solved through the same procedure used to solve Equation (30). However, dialytic elimination of such an equation is not suitable for real-time calculation. To make this process more efficient for real-time control, \( \lambda_{b01} \) (collective pitch input) is considered to be already known. Equation (24) yields:

\[
I_{E_iD_1}^2 = (r_R - L_R \cos \theta_{b01})^2 + (-L_R \sin \theta_{b01} + h - H_R)^2
\]
Therefore, $h$ can be obtained with only one known parameter through Equation (26):

$$h = L_R \sin \theta_{b01} + H_R \pm \sqrt{L^2_{10} - (r_R - L_R \cos \theta_{b01})^2}$$

(27)

Only the smaller solution is acceptable. Substituting the value of $h$ into Equation (25), $\sigma_Z$ and $\sigma_X$ can be easily obtained:

$$\sigma_Z = \kappa_{11} - \nu_{11}, \sigma_X = \kappa_{21} - \nu_{21}$$

(28)

where:

$$\kappa_{ij} = \arcsin \frac{\lambda_{ij}^2 - \mu_{ij}^2 - 1}{2 \sqrt{\mu_{ij}^2 + \lambda_{ij}^2}}, v_{ij} = \arcsin \frac{\mu_{ij}}{\sqrt{\mu_{ij}^2 + \lambda_{ij}^2}}$$

Finally, the inverse kinematics of NR-SM is done in analytical solution with the three given inputs $\{\theta_{b01}|_{\varphi_1=0^\circ}, \theta_{b11}|_{\varphi_2=\sigma_Z}, \}$ and $\{\theta_{b21}|_{\varphi_3=\sigma_X}\}$.

As illustrated in Figure 5, the inverse kinematics of the whole mechanism is derived in an analytical form, which is suitable for real-time control.

![Inverse kinematics of the whole mechanism](image)

**Figure 5.** Inverse kinematics of the whole mechanism for flight control.

### 2.2.2. Direct Kinematic Analysis

Unlike common parallel mechanisms with matching individual loops, the $A_i C_i B_i O$ loop is designed to restrict the DOF. Here, direct position analysis was used to obtain the direct position and orientation of the swashplate, which makes the process more complicated.

According to the characterization presented in Figure 2 for each loop $A_i C_i B_i O, i = 1, 2, 3$, the following vector equation was obtained:

$$\begin{cases} B_i - C_i = (B_i - O) + (O - A_i) + (A_i - C_i) \\ |B_i - C_i| = H \end{cases}$$

(29)

By squaring Equation (29), the following three scalar equations are obtained for $i = 1, 2, 3$:

$$i q_1 S_a S_\beta + i q_2 C_a S_\beta + i q_3 h S_a S_\beta + i q_4 h S_a + i q_5 C_a + i q_6 S_a + i q_7 C_\beta + i q_8 h^2 + i q_9 h + i q_{10} = 0$$

(30)

where $i q_i$ is constant and the values of these variates are defined as $S_a = \sin \alpha$, $C_a = \cos \alpha$, $S_\beta = \sin \beta$, and $C_\beta = \cos \beta$.

Using the well-known Weierstrass expression:

$$\sin \alpha = \frac{2x_2}{1 + x_2^2}, \cos \alpha = \frac{1 - x_2^2}{1 + x_2^2}, \sin \beta = \frac{2x_3}{1 + x_3^2}, \cos \beta = \frac{1 - x_3^2}{1 + x_3^2}$$
where \( x_2 = \tan \frac{\alpha_2}{2} \), \( x_3 = \tan \beta_2 \).

Substituting \( x_1 \) for \( h \), Equation (30) can be transformed into a system of three second-order algebraic equations in the unknowns \( x_1, x_2, x_3 \):

\[
\begin{align*}
2A x_2^2 + 2B x_2 + 2C &= 0 \\
2A x_3^2 + 2B x_3 + 2C &= 0 \\
3A x_3^2 + 2B x_3 + 2C &= 0
\end{align*}
\]  

(31)

When \( i = 2, 3 \), Equation (30) contains all three unknowns, whereas it contains only two unknowns \((x_1, x_2)\) when \( i = 1 \). First, \( x_3 \) can be eliminated from the second and third equation of Equation (31) according to the Sylvester theorem, which will result in an equation in the unknown \( x_1, x_2 \):

\[
\sum_{k=0}^{8} G_k x_2^k = 0
\]  

(32)

where each \( G_k \) is a polynomial of a single indeterminate \( x_2 \).

Then, \( x_2 \) can be eliminated in the same way by combining the Equation (32) and the first equation of the Equation (31). As a result, a polynomial equation in the unknown \( x_1 \) is gained:

\[
\sum_{i=0}^{34} h_i x_1^i = 0
\]  

(33)

where \( h_i \) is constant when the actuators displacements \((\phi_l)\) are given. Equation (33) has 34 simultaneous possible solutions for \( x_1 \), which means that the swashplate mechanism has 34 theoretically possible positions for certain outputs. However, some of the solutions are impossible, and few are acceptable. Moreover, \( x_1 \) can be determined if the initial position of the swashplate mechanism was configured correctly.

If the solution of \( x_1 \) is applied to Equation (33), \( G_k \) is converted into a numerical value. As a result, \( x_2 \) can be solved through Equation (32). Then, \( x_1 \) and \( x_2 \) can be applied to the second and third equation of Equation (31), so that \( x_3 \) is obtained. Finally, the position of the swashplate is uniquely defined.

The purpose of the direct kinematics of the R-SM is to determine the main blade pitch angles \( \{\theta_{b1}, \theta_{b2}\} \) with the given \( \sigma_Z, \sigma_X, h, \) and \( \theta_t \). Firstly, the corresponding \( \phi_t \) can be obtained through Equations (17) and (20). Then, solving Equation (24) for \( \theta_{b1} \) yields:

\[
\theta_{b1} = \kappa + \gamma
\]  

(34)

where:

\[
\kappa = \arcsin \frac{\sqrt{r_{ED}^2 - r_R^2 - l_R^2 - h^2 - 2hr_R \sin \phi_t + 2H_R r_R \sin \phi_t + 2hH_R}}{L_R \sqrt{(2H_R - 2h - 2r_R \sin \phi_t)^2 + (2r_R \cos \phi_t)^2}}
\]

\[
\gamma = \arcsin \frac{2r_R \cos \phi_t}{\sqrt{(2H_R - 2h - 2r_R \sin \phi_t)^2 + (2r_R \cos \phi_t)^2}}
\]

For the blade2, the pitch angle \( \theta_{b2} \) can be easily obtained as:

\[
\theta_{b2}(\theta_t) = \theta_{b1}(\theta_t + 180^\circ)
\]  

(35)

Figure 6 shows the global direct kinematics of the whole mechanism which is a part of the helicopter manipulation. The derived \( \{\theta_{b1}, \theta_{b2}\} \) is needed in the rotor aerodynamics analysis.
2.2.3. Velocity Analysis

As shown in Figure 2, the vector loop of each chain can be written as:

\[
O_0B_i = O_0A_i + A_iC_i + C_iB_i = O_0O + OB_i
\]  

(36)

where the constant magnitude vector connecting an initial point \(A_i\) to a terminal \(C_i\) is denoted by \(A_iC_i\), and so on. Taking the derivative of Equation (36) with respect to time yields two equations. The velocity vector loop of each limb can be written as:

\[
\begin{align*}
V_{B_i} &= w_{A_i} \times A_iC_i + w_{C_i} \times C_iB_i \\
V_{B_i} &= V + \Omega \times OB_i
\end{align*}
\]

(37)

where \(w_{A_i} = u_{A_i}\dot{\phi}_i\), \(V = \begin{bmatrix} 0 & n_y & 0 \end{bmatrix}^T\), \(\Omega = \begin{bmatrix} u_w \dot{\beta} & 0 & \tau_w \dot{\alpha} \end{bmatrix}^T\).

\(u_{A_i}\) is the unit vector along the axis of the \(i\)th actuated joint. \(w_{A_i}\) is the input vector of each actuated joint. To eliminate \(w_{C_i}\), dot multiplication was performed for both sides of Equation (37) with \(C_iB_i\) and the right-hand side was rewritten in matrix form:

\[
\begin{bmatrix}
\dot{\phi}_1 \\
\dot{\phi}_2 \\
\dot{\phi}_3
\end{bmatrix}
= \begin{bmatrix}
\mathbf{u}_{A_1} \cdot (A_1C_i \times C_iB_i) \\
\mathbf{u}_{A_2} \cdot (A_2C_i \times C_iB_i) \\
\mathbf{u}_{A_3} \cdot (A_3C_i \times C_iB_i)
\end{bmatrix}
\begin{bmatrix}
\dot{\phi}_1 \\
\dot{\phi}_2 \\
\dot{\phi}_3
\end{bmatrix}
\]

(38)

The non-rotating submodule is a 3-DOF parallel manipulator, thus eliminating the zero elements in Equation (38), taking \(\dot{\mathbf{x}} = \begin{bmatrix} \dot{h} & \dot{\beta} & \dot{\alpha} \end{bmatrix}^T\) as the input vector of actuated joints. Using \(\mathbf{x} = \begin{bmatrix} \dot{h} & \dot{\beta} & \dot{\alpha} \end{bmatrix}^T\) represents the linear and angular velocities of the moving swashplate. Therefore, we can write Equation (38) in a 3 \(\times\) 3 matrix form:

\[
\begin{bmatrix}
\mathbf{u}_{A_1} \cdot (A_1C_i \times C_iB_i) \\
\mathbf{u}_{A_2} \cdot (A_2C_i \times C_iB_i) \\
\mathbf{u}_{A_3} \cdot (A_3C_i \times C_iB_i)
\end{bmatrix}
\begin{bmatrix}
\dot{\phi}_1 \\
\dot{\phi}_2 \\
\dot{\phi}_3
\end{bmatrix}
= \begin{bmatrix}
n_y \cdot C_iB_1 \\
n_y \cdot C_iB_2 \\
n_y \cdot C_iB_3
\end{bmatrix}
\begin{bmatrix}
\tau_w \cdot (C_1B_1 \times B_1O) \\
\tau_w \cdot (C_2B_2 \times B_2O) \\
\tau_w \cdot (C_3B_3 \times B_3O)
\end{bmatrix}
\begin{bmatrix}
\dot{h} \\
\dot{\beta} \\
\dot{\alpha}
\end{bmatrix}
\]

(39)

For \(A_iC_i \times C_iB_i \neq 0\), Equation (39) is a three scalar equation which can be written as:

\[
\dot{\mathbf{q}} = I_N\dot{\mathbf{x}}
\]

(40)
where:

\[
\mathbf{J}_{\text{NR}} = \begin{bmatrix}
  n_y C_1 B_1 & u_w (C_1 B_1 \times B_1) & \tau_w (C_1 B_1 \times B_1) \\
  u_{A_1} (C_1 C_1 \times C_1 B_1) & n_y C_2 B_2 & u_w (C_2 B_2 \times B_2) & \tau_w (C_2 B_2 \times B_2) \\
  u_{A_2} (C_1 C_2 \times C_2 B_2) & n_y C_3 B_3 & u_w (C_3 B_3 \times B_3) & \tau_w (C_3 B_3 \times B_3) \\
  u_{A_3} (C_1 C_3 \times C_3 B_3) & & & \\
\end{bmatrix}
\]

which is known as the manipulator Jacobian matrix.

As mentioned above, the R-SM rotates around the main shaft as a unity. First, we derive the velocity relations and the link Jacobian matrix for the R-SM with respect to the local frame \(X'_0Y'_0Z'_0\). \(\dot{\mathbf{q}} = \begin{bmatrix} \dot{\theta}_{b_1} & \dot{\theta}_{b_2} \end{bmatrix}^T\) was taken as the input vector of the main blades. Using \(\mathbf{x} = \begin{bmatrix} \dot{h} & \dot{\beta}' & \dot{\alpha}' \end{bmatrix}^T\) represents the linear and angular velocities of the swashplate. Referring to Figure 4, the vector loop for each blade side can be written as:

\[
\mathbf{O}E_i = \mathbf{O}_4 F + \mathbf{F}E_i = \mathbf{O}_4 + \mathbf{O}D_i + \mathbf{D}_i E_i
\]  

(41)

Taking the derivative of Equation (41) with respect to time yields:

\[
\dot{\mathbf{V}}E_i = \dot{\theta}_{b_i} u_{\theta_{b_i}} \times \mathbf{F}E_i = \dot{\mathbf{V}}' + \Omega' \times \mathbf{OD}_i + \mathbf{wD}_i \times \mathbf{D}_i E_i
\]

(42)

where \(\mathbf{wD}_i\) is the unit vector along the feathering axis of blade \(i\).

To eliminate the \(\mathbf{wD}_i\), dot multiplication was performed for each side of Equation (42) with \(\mathbf{D}_i E_i\) and the right-hand side was rewritten in matrix form:

\[
\begin{bmatrix} u_{\theta_{b_i}} \cdot (\mathbf{FE}_i \times \mathbf{D}_i E_i) \end{bmatrix} \begin{bmatrix} \dot{\theta}_{b_i} \end{bmatrix} = \begin{bmatrix} n_y \cdot \mathbf{D}_i E_i \quad u_w \cdot (\mathbf{OD}_i \times \mathbf{D}_i E_i) \quad \tau_w \cdot (\mathbf{OD}_i \times \mathbf{D}_i E_i) \end{bmatrix} \begin{bmatrix} \dot{\alpha}' \quad \dot{\beta}' \quad \dot{\gamma}' \end{bmatrix}^T
\]

(43)

Rewriting Equation (42) gives:

\[
\begin{bmatrix} \dot{\theta}_{b_1} & \dot{\theta}_{b_2} \end{bmatrix}^T = \mathbf{J}'_\mathbf{R} \begin{bmatrix} \dot{\alpha}' \quad \dot{\beta}' \quad \dot{\gamma}' \end{bmatrix}^T
\]

(44)

where:

\[
\mathbf{J}'_\mathbf{R} = \begin{bmatrix}
  \mathbf{J}'_{1\alpha} & \mathbf{J}'_{1\beta} & \mathbf{J}'_{1\gamma} \\
  \mathbf{J}'_{2\alpha} & \mathbf{J}'_{2\beta} & \mathbf{J}'_{2\gamma} \\
\end{bmatrix}
\]

The velocities of the rotating part of swashplate can be expressed with respect to the initial frame \(X_4Y_4Z_4\):

\[
\mathbf{V} = \mathbf{R}_Y (\theta_1)^T \begin{bmatrix} 0 & \dot{\alpha}' & 0 \end{bmatrix} + \mathbf{\dot{\alpha}} + \mathbf{\Omega}^T \begin{bmatrix} \dot{\alpha}' & 0 & 0 \end{bmatrix}^T
\]

(45)

Hence, the Jacobian matrix of the R-SM can be obtained:

\[
\mathbf{J}_\mathbf{R} = \begin{bmatrix}
  \mathbf{J}'_{1\alpha} & \mathbf{J}'_{1\beta} & \mathbf{J}'_{1\gamma} \\
  \mathbf{J}'_{2\alpha} & \mathbf{J}'_{2\beta} & \mathbf{J}'_{2\gamma} \\
  0 & \mathbf{n}_y^T \\
\end{bmatrix}
\]

(46)

where \(\mathbf{R}_Y (\theta_1)\) is the rotation matrix of the local frame \(X'_0Y'_0Z'_0\) relative to the initial frame \(X_4Y_4Z_4\) and \(\mathbf{J}_\mathbf{aw} = \begin{bmatrix} \mathbf{J}'_{1\beta} & 0 & \mathbf{J}_{1\alpha}' \end{bmatrix}^T\).
2.2.4. Acceleration Analysis

In this section, we derive the relationships between the angular acceleration of the actuated joint and the linear and angular accelerations of the moving swashplate. The rules of taking the derivative of a vector with respect to time defined as:

\[
\left\{ \begin{array}{c}
\frac{d}{dt}A_iC_i = w_{A_i} \times A_iC_i \\
\frac{d}{dt}(A_iC_i \times C_iB_i) = \left(w_{A_i} \times A_iC_i\right) \times C_iB_i + A_iC_i \times \left(w_{C_i} \times C_iB_i\right)
\end{array} \right.
\]

(47)

Taking the derivative of the right-hand sides of Equation (37) with respect to time yields:

\[
\begin{align*}
\begin{cases}
a_B = \dot{V}_B = w_{A_1} \times A_1C_1 + \dot{w}_A \times \left(w_{A_1} \times A_1C_1\right) + \dot{w}_C \times C_1B_1 + w_{C_1} \times \left(w_{C_1} \times C_1B_1\right) \\
a_B = \dot{V}_B = V + B_iO \times \Omega + (B_iO \times \Omega) \times \Omega
\end{cases}
\end{align*}
\]

(48)

Dot multiplying both sides of Equation (48) with \(C_iB_i\) and rewriting it in matrix form gives:

\[
\begin{bmatrix}
\ddot{\varphi}_1 \\
\ddot{\varphi}_2 \\
\ddot{\varphi}_3
\end{bmatrix} = \left[
\begin{array}{ccc}
\ddot{h} & \ddot{\beta} & \ddot{\alpha}
\end{array}\right]^T + \begin{bmatrix}
\xi_1 \\
\xi_2 \\
\xi_3
\end{bmatrix}
\]

where:

\[
\xi_i = \frac{(A_iC_i \cdot C_iB_i)\dot{\varphi}_i^2 + \left(C_iB_i \cdot C_iB_i\right)\left(w_{C_i} \cdot w_{C_i}\right) + \left(\Omega \cdot C_iB_i\right)(\Omega \cdot OB_i) - \left(\Omega \cdot C_iB_i\right)(\Omega \cdot \Omega)}{u_A \cdot (A_iC_i \times C_iB_i)}
\]

To derive the angular velocity of the lower rod \(w_{C_i}\), cross multiplication was performed for both sides of Equation (37) with \(C_iB_i\). Since each rod does not spin about its own axis, we obtain:

\[
w_{C_i} = \frac{1}{|C_iB_i|^2}\left[C_iB_i \times V + B_iO \cdot (C_iB \cdot \Omega) - \Omega \cdot (C_iB \cdot B_iO) - w_{A_i} \cdot (C_iB_i \cdot A_iC_i) + A_iC_i \cdot (C_iB_i \cdot w_{A_i})\right]
\]

(50)

where \(|C_iB_i|\) expresses the module of vector \(C_iB_i\).

The acceleration relationships of R-SM can be derived in the same way used above. First, taking the derivative of the right-hand sides of Equation (42) with respect to time yields:

\[
\begin{align*}
\begin{cases}
\tilde{\theta}_{i}u_{\theta_i} \times FE_i + \tilde{\theta}_{i}u_{\theta_i} \times \left(\tilde{\theta}_{i}u_{\theta_i} \times FE_i\right) \\
= V' + \Omega' \times OD_i + \Omega' \times (\Omega' \times OD_i) + \dot{w}_{D_i} \times D_iE_i + w_{D_i} \times \left(w_{D_i} \times D_iE_i\right)
\end{cases}
\end{align*}
\]

(51)

Dot multiplying both sides of Equation (51) with \(D_iE_i\) and rewriting it in matrix form gives:

\[
\begin{bmatrix}
\tilde{\theta}_{i1} \\
\tilde{\theta}_{i2}
\end{bmatrix} = \left[
\begin{array}{ccc}
\varphi'_{h} & \varphi'_{\beta} & \varphi'_{\alpha}
\end{array}\right]^T + \begin{bmatrix}
\xi'_{1} \\
\xi'_{2}
\end{bmatrix}
\]

(52)

where:

\[
\xi'_{i} = \frac{(FE_i \cdot D_iE_i)\tilde{\theta}_{i}^2 + (\Omega \cdot D_iE_i)(\Omega \cdot OD_i) - (OD_i \cdot D_iE_i)(\Omega \cdot \Omega) + (D_iE_i \cdot D_iE_i)(w_{D_i} \cdot w_{D_i})}{u_{\theta_i} \cdot (D_iE_i \times FE_i)}
\]

To derive the angular velocity of the upper rod \(w_{D_i}\), which is the only unknown parameter, cross multiplication was performed for both sides of Equation (42) with \(D_iE_i\), which gives:

\[
w_{D_i} = \frac{D_iE_i}{|D_iE_i|^2} \times \left(\tilde{\theta}_{i}u_{\theta_i} \times FE_i - V' - \Omega' \times OD_i\right)
\]

(53)
2.3. Inverse Dynamic Analysis

According to d’Alembert’s principle, the resultant of the applied and inertia forces exerted at the center of mass of the \( i \)th body of a mechanism consists of \( N \) components is:

\[
F_i = \begin{bmatrix} f_i \\ n_i \end{bmatrix} = \begin{bmatrix} f_e + m_i g - m_i \ddot{v}_i \\ n_e - I_i \ddot{w}_i - w_i \times (I_i \ddot{w}_i) \end{bmatrix}
\]

\( (54) \)

where \( f_e \) and \( n_e \) are the external force and moment applied at the center of mass of component \( i \). \( \ddot{v}_i \) and \( \ddot{w}_i \) are the translational acceleration and angular acceleration. \( g \) and \( I_i \) are the gravitational acceleration and inertial matrix.

Combining d’Alembert’s principle and the traditional principle of virtual work contributes to the critical step in the dynamic analysis:

\[
\delta q^T \tau + \sum_{i=1}^{n} \delta x_i^T F_i = 0 \quad (55)
\]

where \( \delta q \) and \( \delta x_i \) are the virtual displacements of the actuated joints and \( i \)th component, respectively. In this step, we relate the virtual displacements to the generalized virtual displacement of the moving platform by the Jacobian matrices. For each part:

\[
\delta q = J_i \delta x_i \quad (56)
\]

Substituting Equation (56) into Equation (55) yields:

\[
\delta q^T (\tau + \sum_{i=1}^{n} J_i^{-T} F_i) = 0 \quad (57)
\]

Since Equation (57) is valid for any \( \delta q \), it follows that:

\[
\tau + \sum_{i=1}^{n} J_i^{-T} F_i = 0 \quad (58)
\]

This step makes the dynamic modeling more efficient than the traditional ways, which is similar to Kane’s formulation.

For the \( A_1C_1 \) rocker, the velocity vector of its center can be written as:

\[
J_{A_1C_1}^1 \dot{q} = x_{A_1C_1} \quad (59)
\]

where:

\[
\dot{x}_{A_1C_1} = \begin{bmatrix} -c_{A_1C_1} \dot{\varphi}_1 \sin \varphi_1 \\ c_{A_1C_1} \dot{\varphi}_1 \cos \varphi_1 \end{bmatrix}
\]

\[
A_{A_1C_1}^1 = \begin{bmatrix} -c_{A_1C_1} \sin \varphi_1 & 0 & 0 \\ c_{A_1C_1} \cos \varphi_1 & 0 & 0 \\ 1 & 0 & 0 \end{bmatrix}
\]

and where \( \dot{q} = \begin{bmatrix} \dot{\varphi}_1 \\ \dot{\varphi}_2 \\ \dot{\varphi}_3 \end{bmatrix}^T \) is the input vector of actuated joints of NR-SM. It is not difficult to find that \( J_{A_1C_1}^1 \) has the same form, as only the \( i \)th column is not zero. The resultant of applied and inertia forces exerted at the center of mass of the \( i \)th rocker is:

\[
F_{A_iC_i} = \begin{bmatrix} m_{A_iC_i} g - m_{A_iC_i} \ddot{v}_{A_iC_i} \\ -I_{z,A_iC_i} \ddot{\varphi}_i \end{bmatrix}
\]

\( (60) \)
where $I_{2A,C_1}$ is the $z$ component of the moment of inertia of rocker $A_1C_1$ around its mass center. Thus, the desired expression can be rewritten as:

$$\sum_{i=1}^{3} \int_{A_{C_1}}^{B_{C_1}} F_{A_{C_1}} = \begin{bmatrix} \lambda_1 & \lambda_2 & \lambda_3 \end{bmatrix}^T$$

(61)

where $\lambda_i = -m_{A,C}c_{A,C_i}^2 \bar{\varphi}_i - I_{2A,C} \bar{\varphi}_i - m_{A,C}g c_{A,C_i} \cos \varphi_i$, and $c_{A,C_i}$ is the distance between point $A_i$ and the center of mass of rocker $A_iC_i$.

For the non-rotating part of swashplate, the resultant of applied and inertia forces exerted at its center of mass can be expressed in the desired three-dimensional form by eliminating the zero elements:

$$F_{NR} = \begin{bmatrix} f_{x,y} - m_{NR}(g + \bar{h}) \ n_{e,x} + n_{NR,x} \ n_{e,z} + n_{NR,z} \end{bmatrix}^T$$

(62)

where $f_{x,y}$ is the external force along $Y$ axis exerted at the center of mass of the non-rotating swashplate, and $n_{e,x}$ and $n_{e,z}$ are the external and inertia moments about $X$ ($Z$) axis, respectively.

Hence, for the NR-SM Equation (58) can be written as:

$$\tau_{NR} = -\sum_{i=1}^{3} \int_{A_{C_1}}^{B_{C_1}} F_{A_{C_1}} - \int_{NR}^{F_{NR}} = 0$$

(63)

where $\tau_{NR}$ is the desired actuated torque. Note that the assistant lower rods are neglected in the dynamic modeling process of the NR-SM due to their light weights and low velocities. Only $f_{x,y}$, $n_{e,x}$, and $n_{e,z}$ are unknown in the right-hand side of Equation (63).

Note that the linear velocity of each blade does not exist and the external force does not contribute to the dynamic modeling. Therefore, for the blade1, the velocity vector of its center can be written as:

$$w_{b1} = \begin{bmatrix} \dot{\theta}_{b1} \sin \theta_1 & \dot{\theta}_{b1} \cos \theta_1 & \dot{\theta}_1 \end{bmatrix}^T$$

and

$$\dot{w}_{b1} = \begin{bmatrix} \dot{\theta}_{b1} \sin \theta_1 & \dot{\theta}_{b1} \cos \theta_1 & \dot{\theta}_1 \end{bmatrix}^T$$

(64)

and where $\dot{q} = \begin{bmatrix} \dot{\theta}_{b1} & \dot{\theta}_{b2} & \dot{\theta}_1 \end{bmatrix}^T$ is the input vector of actuated joints of R-SM. Equation (54) can be written as:

$$F_{b1} = \begin{bmatrix} -m_{b1} \dot{w}_{b1} \times c_{b1} & -I_{b1} \dot{\omega}_{b1} \times \dot{\omega}_{b1} \end{bmatrix}$$

(65)

where $I_{b1} = \text{diag}([I_{b1,x}, I_{b1,y}, I_{b1,z}])$ is diagonal inertia matrix and $I_{b1,x}$, $I_{b1,y}$, and $I_{b1,z}$ are the indicate the principle moments of inertia of main blades. $\dot{\omega}_{b1}$ is $\omega_{b1}$ expressed in the local frame $X_1Y_1Z_1$, and so on. Thus, the desired equations can be derived by assembling the relations of two blades and eliminating some zero elements:

$$\sum_{i=1}^{2} \int_{b_i}^{F_{b_i}} = \begin{bmatrix} J_{b1} & J_{b2} & J_{b3} \end{bmatrix}^T$$

(66)

where:

$$J_{b_j} = \sum_{i=1}^{2} \left( I_{b_i,j,x} I_{b_i,j,x} + I_{b_i,j,y} I_{b_i,j,y} + I_{b_i,j,z} I_{b_i,j,z} \right) + J_{b,j,m}$$
and where:
\[
\begin{align*}
J_{b1,1,x} &= \dot{\theta}_1 \sin \theta_{b1} \cos \theta_{b1}, \quad J_{b1,1,y} = -J_{b1,1,x}, J_{b1,1,z} = -\dot{\theta}_{b1}, J_{b1,2,x} = J_{b1,2,y} = J_{b1,2,z} = 0, \\
J_{b2,1,x} &= J_{b2,1,y} = J_{b2,1,z} = 0, \quad J_{b2,2,x} = J_{b2,1,x}, J_{b2,2,y} = J_{b1,1,y}, J_{b2,2,z} = J_{b1,1,z}, \\
J_{b3,1,x} &= -2\dot{\theta}_1 \dot{\theta}_{b1} \sin^2 \theta_{b1} - \dot{\theta}_1 \sin\theta_{b1} - \dot{\theta}_{b1} \cos \theta_{b1} - \dot{\theta}_1 \cos^2 \theta_{b1}, \\
J_{b3,1,y} &= 2\dot{\theta}_1 \dot{\theta}_{b1} \sin \theta_{b1} \cos \theta_{b1} - \dot{\theta}_1 \cos \theta_{b1} - \dot{\theta}_1 \cos \theta_{b1}, \\
J_{b3,1,z} &= 0, J_{b1,m} = J_{b2,m} = 0, J_{b3,m} = -2m_b c^2 \dot{\theta}_1.
\end{align*}
\]

For the blade holder \( b_i \) of blade \( 1 \), the angular and linear velocity transformed to the frame \( X_4Y_4Z_4 \) can be derived as:
\[
\begin{align*}
\mathbf{w}_{bh1} &= \mathbf{w}_{b1} = \begin{bmatrix} \dot{\theta}_{b1} \sin \theta_{b1} & \dot{\theta}_1 & \dot{\theta}_{b1} \cos \theta_{b1} \end{bmatrix}^T, \\
\mathbf{w}_{bh1} &= \begin{bmatrix} \dot{\theta}_{b1} - c_{b,1} x_{bh1} \sin \theta_{b1} + c_{b,2} \cos \theta_{b1} \end{bmatrix} \dot{\theta}_{b1} - c_{b,1} x_{bh1} \sin \theta_{b1} + c_{b,2} \cos \theta_{b1} \end{bmatrix}^T, \\
\mathbf{v}_{bh1} &= \mathbf{w}_{b1} \times \mathbf{c}_{bh1} = \begin{bmatrix} -c_{b,1} x_{bh1} \sin \theta_{b1} \cos \theta_{b1} - c_{b,2} \cos \theta_{b1} \sin \theta_{b1} \\
\theta_{b1} c_{b,1} x_{bh1} \cos \theta_{b1} \\
c_{b,2} \sin \theta_{b1} \cos \theta_{b1} - c_{b,2} \sin \theta_{b1} \cos \theta_{b1} \\
0 \\
0 \\
0 \\
1 \end{bmatrix},
\end{align*}
\]
where \( \mathbf{c}_{bh1} \) is the position vector of the center of mass of blade holder \( b_i \). Therefore, the Jacobian matrix is given by:
\[
F_{bh1} = \begin{bmatrix} -c_{b,1} x_{bh1} \sin \theta_{b1} \cos \theta_{b1} & 0 & -c_{b,2} \cos \theta_{b1} \sin \theta_{b1} + c_{b,2} \cos \theta_{b1} \\
\theta_{b1} c_{b,1} x_{bh1} \cos \theta_{b1} & 0 & 0 \\
c_{b,2} \sin \theta_{b1} \cos \theta_{b1} - c_{b,2} \sin \theta_{b1} \cos \theta_{b1} & 0 & \sin \theta_{b1} \\
0 & 0 & \cos \theta_{b1} \\
0 & 1 & 0 \end{bmatrix},
\]
\[
\sum_{i=1}^{2} F_{bh1}^T F_{bh1} = \begin{bmatrix} J_{bh1} & J_{bh2} & J_{bh3} \end{bmatrix}^T
\]
where:
\[
\begin{align*}
J_{bh1} &= c_{b,1} x_{bh,1,1} + J_{bh,6,1}, J_{bh2} = c_{b,1} x_{bh,2,2} + J_{bh,6,2}, \\
J_{bh3} &= \sum_{i=1}^{2} \left(c_{b,2} \cos \theta_{bi} x_{bh,1,1,1} - c_{b,2} \sin \theta_{bi} x_{bh,1,1,2} - c_{b,1} x_{bh,3,1,2} \cos \theta_{bi} x_{bh,3,1,1} + \sin \theta_{bi} x_{bh,4,1} + \cos \theta_{bi} x_{bh,5,1} \right)
\end{align*}
\]
and where:
\[
\begin{align*}
J_{bh,1,1,i} &= -m_{bh} c_{b,x} \dot{\theta}_i \cos \theta_{bi} + m_{bh} c_{b,x} \dot{\theta}_i \dot{\theta}_{bi} \sin \theta_{bi} - m_{bh} g \sin \theta_{bi}, \\
J_{bh,2,1,i} &= -m_{bh} c_{b,x} \dot{\theta}_i \cos \theta_{bi} + m_{bh} c_{b,x} \dot{\theta}_i \dot{\theta}_{bi} \sin \theta_{bi} - m_{bh} g \cos \theta_{bi}, \\
J_{bh,3,1,i} &= m_{bh} c_{b,x} \dot{\theta}_i \cos \theta_{bi} - m_{bh} c_{b,x} \dot{\theta}_i \dot{\theta}_{bi} \sin \theta_{bi}, \\
J_{bh,4,1,i} &= -I_{bh,x} \dot{\theta}_i \sin \theta_{bi} + \dot{\theta}_i \dot{\theta}_{bi} \cos \theta_{bi} - \left( I_{bh,z} - I_{bh,y} \right) \dot{\theta}_i \dot{\theta}_{bi} \cos \theta_{bi} - m_{bh} g c_{b,x} \cos \theta_{bi}, \\
J_{bh,5,1,i} &= -I_{bh,x} \dot{\theta}_i \cos \theta_{bi} - \dot{\theta}_i \dot{\theta}_{bi} \sin \theta_{bi} - \left( I_{bh,z} - I_{bh,y} \right) \dot{\theta}_i \dot{\theta}_{bi} \sin \theta_{bi}, \\
J_{bh,6,1,i} &= -I_{bh,x} \dot{\theta}_i - \left( I_{bh,y} - I_{bh,x} \right) \dot{\theta}_i \dot{\theta}_{bi} \sin \theta_{bi} \cos \theta_{bi}
\end{align*}
\]
For the rotating swashplate, the applied and inertia wrenches can be written as:
\[
F_R = \begin{bmatrix} f_{c,x} - m_R \left( g + \dot{h} \right) \\
n_{c,x} + n_{R,x} \\
n_{c,y} + n_{R,y} \\
n_{c,z} + n_{R,z} \end{bmatrix}
\]
where \( f_{e,y} \) is the external force along \( Y \) axis exerted at the center of mass of rotating swashplate, and \( n_{e,x} \) and \( n_{NR,x} \) (\( n_{e,y} \) and \( n_{NR,y} \); \( n_{e,z} \) and \( n_{NR,z} \)) are the external and inertia moments along the \( X \) (\( Y \); \( Z \)) axis, respectively. Additionally, upper rods are neglected in the dynamic modeling process of the R-SM. To express the desired \( f_{e,y} \), \( n_{e,x} \), and \( n_{e,z} \), Equation (58) can be rewritten as:

\[
F_R = -J^T_R \left( \tau_R + \sum_{i=1}^{2} J_{bh_i}^T F_{bh_i} + \sum_{i=1}^{2} J_{b_i}^T F_{b_i} \right)
\]  

(71)

Given the actuated torques, \( \tau_R \), \( f_{e,y} \), \( n_{e,x} \), and \( n_{e,z} \) can be solved with Equation (71). Then, by substituting \( f_{e,y} \), \( n_{e,x} \), and \( n_{e,z} \) into Equation (63), \( \tau_{NR} \) can be finally determined. Thus far, the inverse dynamic model of the whole mechanism has been established.

3. Results and Discussions

3.1. Numerical Validation

In this section, a numerical example is provided to exemplify the proposed methodology. First, the rigid body model of the whole swashplate mechanism is built and simulated using RecurDyn V9R1. Then, a computer program is developed using Matlab based on the mathematical model. Finally, the simulation results are compared with the analytical results.

The kinematic and dynamic parameters are given in Table 1. The rotation rate of the main shaft is 150 rpm.

| Parameters | Moment of Inertia (\( \times 10^{-6} \text{ Kg m}^2 \)) | Parameters | Length (mm) | Parameters | Weight (\( \times 10^{-5} \text{ Kg} \)) |
|------------|---------------------------------|------------|-------------|------------|-----------------|
| \( I_{NR,x} \) | 13.403 | \( L \) | 25 | \( m_{A_1C_1} \) | 1.776 |
| \( I_{NR,y} \) | 26.591 | \( c_{A_1C_1} \) | 12.02 | \( m_{A_2C_2} \) | 1.702 |
| \( I_{NR,z} \) | 13.403 | \( c_{A_2C_2} \) | 11.73 | \( m_{A_3C_3} \) | 1.702 |
| \( I_{R,x} \) | 9.462 | \( c_{A_3C_3} \) | 11.73 | \( m_{b_h} \) | 85.56 |
| \( I_{R,y} \) | 19.117 | \( r \) | 44.5 | \( m_{R} \) | 52.32 |
| \( I_{R,z} \) | 9.793 | \( H = H_R \) | 60 | \( m_{NR} \) | 58.53 |
| \( I_{bh,x} \) | 23.282 | \( L_R \) | 30 | \( \) | \( \) |
| \( I_{bh,y} \) | 26.780 | \( r_R \) | 30 | \( \) | \( \) |
| \( I_{bh,z} \) | 6.316 | \( c_{b,x} \) | 1.86 | \( \) | \( \) |
| \( I_{b,x} \) | 793.943 | \( c_{b,z} \) | 54.74 | \( \) | \( \) |
| \( I_{b,y} \) | 794.929 | \( l_{b,C_i} \) | 60 | \( \) | \( \) |
| \( I_{b,z} \) | 1.048 | \( l_{E,D_i} \) | 60 | \( \) | \( \) |

The displacements of three actuators are expressed as:

\[
\begin{align*}
\varphi_1 &= 0.4 \sin(13t) \cos(12t) \\
\varphi_2 &= 0.5 \sin(15t) \cos(11t) \\
\varphi_3 &= 0.3 \sin(7t)
\end{align*}
\]  

(72)

The motion considered for each actuator and the analytical results calculated through the inverse kinematic model are shown in Figure 7a. As indicated in Figure 7b, the accuracy of such a model is verified. For the direct kinematics, the simulation and analytical results of two blades’ pitch angles are shown in Figure 8a. The simulation and analytical results match well in all simulation cases. This shows that the direct kinematic model is correct. The corresponding errors shown in Figure 8b are acceptable.
Table 1. Parameters of the swashplate mechanism.

| Parameters | Moment of Inertia \((\text{m}^2 \cdot \text{Kg} \cdot \text{m}^2) \times 10^6\) | Length (mm) | Weight (\(\text{Kg}\)) |
|------------|-------------------------------------------------|-------------|----------------------|
| \(\text{NR,xI}\) | 13.403 | 9.462 | 793.943 |
| \(\text{NR,yI}\) | 26.591 | 19.117 | 794.929 |
| \(\text{NR,zI}\) | 13.403 | 9.793 | 58.53 |
| \(\text{R,xI}\) | 9.462 | 9.462 | 85.56 |
| \(\text{R,yI}\) | 19.117 | 19.117 | 52.32 |
| \(\text{R,zI}\) | 9.793 | 9.793 | 58.53 |
| \(\text{bh,xI}\) | 23.282 | 793.943 | 23.282 |
| \(\text{bh,yI}\) | 26.780 | 794.929 | 26.780 |
| \(\text{bh,zI}\) | 6.316 | 54.74 | 6.316 |
| \(\text{iiCBl}\) | 60 | 60 | 60 |
| \(\text{ii DEl}\) | 60 | 60 | 60 |

The displacements of three actuators are expressed as:

\[ \begin{align*}
\phi_1(t) &= 70.3 \sin(\pi t) \cos(\pi t) \\
\phi_2(t) &= 11.3 \cos(\pi t) \\
\phi_3(t) &= 13.4 \sin(\pi t - \pi) \cos(\pi t) \\
\end{align*} \]  

(72)

Figure 7. (a) Comparison of the setting motion for each actuator in RecurDyn and the analytical results obtained by the inverse kinematic model; (b) the relative errors between the mathematical model and the rigid body model.

To verify the inverse dynamic model and make the results more obvious, the moments generated by two blades are set in simple form instead of using the blade element theory. Additionally, through dynamic analysis, we note that the driving torque of the main shaft does not change the results in the calculating process. Therefore, the loads are given as:

\[ \tau_R = \begin{bmatrix}
A_m \sin(\pi t) \cos(\pi t) \\
A_m \sin(\pi t - \pi) \cos(\pi t) \\
0
\end{bmatrix}^T \]  

(73)

As summarized in Figure 9, for \(A_m = 600 \text{ N-mm}\), the simulation results match well with the analytical results of the complete model. This verifies the correctness of the presented inverse dynamic model of the FBL swashplate mechanism.
Figure 7. (a) Comparison of the setting motion for each actuator in RecurDyn and the analytical results obtained by the inverse kinematic model; (b) the relative errors between the mathematical model and the rigid body model.

Figure 8. (a) Comparison of the simulation pitch angles of the two main blades and the analytical results obtained by the direct kinematic model; (b) the relative errors between the mathematical model and the rigid body model.

To verify the inverse dynamic model and make the results more obvious, the moments generated by two blades are set in simple form instead of using the blade element theory. Additionally, through dynamic analysis, we note that the driving torque of the main shaft does not change the results in the calculating process. Therefore, the loads are given as:

\[
\tau_{\text{R}} = \begin{bmatrix}
\cos(\sin(\pi t)) & \cos(\sin(\pi tA)) \\
0 & 0
\end{bmatrix}
\]  \hspace{1cm} (73)

As summarized in Figure 9, for \(mN = 600\), the simulation results match well with the analytical results of the complete model. This verifies the correctness of the presented inverse dynamic model of the FBL swashplate mechanism.

Figure 9. Comparison of the calculated torques and the simulated driving torques of three actuators. Red and blue solid lines are obtained by the proposed complete inverse dynamic model, while neglecting the rods, and the simplified inverse dynamic model, while neglecting all of the components, respectively.
3.2. Simulation Results and Analysis

As the inverse dynamic model has been proven to be correct, a series of simulation can be conducted for the actuators’ load analysis. As mentioned in the dynamic modeling process, the rods have been neglected. In fact, the dynamic analysis of the rods is very difficult. Thus, neglecting them simplifies the dynamic model. If other components of the swashplate mechanism are neglectable, the dynamic model will be more efficient. Therefore, we neglect all the components of the swashplate mechanism, which means the simplified model only considers the loads \( \tau_R \). As shown in Figure 9, the driving torques determined with the simplified model are illustrated with blue solid curves. It can be observed that the simplified model also agrees with the rigid body model. The comparison of the results illustrates that neglecting the dynamic contribution of the rods is reasonable. From the perspective of the entire simulation process, the equilateral triangle arrangement of these three actuators realizes a uniform distribution of the load.

The torque contribution of the components in Equation (63) can be further analyzed; as shown in Figure 10, for \( A_m = 0 \text{ N-mm} \), there is no external force exerted on the blades, and the amplitude of the torques resulting from the inertial part is quite small compared with the torques resulting from the blade loads. The torque contribution of each part of the driving torque is shown in Figure 11. Obviously, the torque contributions of the input rocker and the inertial part of the main blade are very small and the swashplate is the dominant and most violet component. Therefore, further research on the rods to improve the model accuracy is meaningless.

![Figure 10](image-url)

**Figure 10.** The applied torques on the actuators while only the inertial forces of the components are considered.
The torque contribution of the components in Equation (63) can be further analyzed; as shown in Figure 10, for \( \text{mmN} \cdot \text{Am}_0 \), there is no external force exerted on the blades, and the amplitude of the torques resulting from the inertial part is quite small compared with the torques resulting from the blade loads. The torque contribution of each part of the driving torque is shown in Figure 11. Obviously, the torque contributions of the input rocker and the inertial part of the main blade are very small and the swashplate is the dominant and most vital component. Therefore, further research on the rods to improve the model accuracy is meaningless.

Figure 10. The applied torques on the actuators while only the inertial forces of the components are considered.

Figure 11. Contributions of each component on the driving torque: (a) actuator 1; (b) actuator 2; (c) actuator 3.

4. Conclusions

The kinematics and inverse dynamics of an FBL swashplate mechanism are analyzed in this paper. A novel comprehensive model is derived. An analytical model for the kinematics is built up based on the parallel robots concepts, including three levels: position, velocity, and acceleration. Based on the principle of virtual work, a novel closed-form dynamics model is established, which could be...
incorporated in the real-time attitude controller. Such a model provides an effective method to analyze the sources of the actuators’ load.

By comparing the Recurdyn simulation results with the analytical results derived from the mathematical model we obtained, the novel comprehensive kinematic model proved to be precise enough for the control system design. The dynamic model proved to be capable to predict the loads that acted on actuators of such a mechanism, and the dominant impact of the blade loads of the FBL swashplate mechanism on the driving torques was analyzed with a numerical simulation. From the simulation results, we could find that the aerodynamic hinge moments that acted on the rotating blades were the main sources of the actuators’ load and were the main factor to influence the oscillating dynamic loads for the three actuators. The inertial forces of the FBL swashplate mechanism components have little effect on the actuators. The simplified model may be more practical in the controller design progress, as neglecting the components makes the calculation more efficient.

In future work, combined with a complete aerodynamic rotor theory, a more in-depth research of the actuators’ loads can be done under real flight conditions, which can benefit the design of the controller of the actuator. Furthermore, the vibration characteristics of each component can be analyzed in detail. Additionally, the kinematic and dynamic model lay a foundation for the optimization of the FBL swashplate mechanism.

Author Contributions: Conceptualization, H.W. and L.H.; methodology, J.L. and Y.Y.; software, J.L.; validation, R.G. and L.H.; investigation, H.W.; resources, L.H.; data curation, J.L.; writing—original draft preparation, J.L.; writing—review and editing, Y.Y., R.G., and H.W.; supervision, Y.Y.; project administration, R.G. and L.H.; funding acquisition, Y.Y. All authors have read and agreed to the published version of the manuscript.

Funding: This work is supported by the National Key R&D Program of China (Grant No. 2017YFC0602000) and the Science and Technology Development Project of Jilin Province (Grant No. 20190303061SF).

Conflicts of Interest: The authors declare no conflict of interest. The funders had no role in the design of the study; in the collection, analyses, or interpretation of data; in the writing of the manuscript; or in the decision to publish the results.
