Received: date / Accepted: date

Abstract In this paper, a novel Sr$_{0.97}$Ba$_{0.03}$TiO$_{3-\delta}$ memristor based fifth-order chaotic circuit was proposed. A new cubic nonlinear magnetic control model was established by analyzing the measured data. The equilibrium points and its stability of the circuit system were analyzed by the Jacobi matrix method, and the effects of the initial states and circuit parameters on the system were discussed through methods of Lyapunov exponents spectra, bifurcation diagrams, phase diagrams, and poincaré maps. The results show that the chaotic circuit can produce complex dynamic phenomena with the variation of initial states and circuit parameters. The dynamic phenomena such as coexisting attractors have been discovered. In particular, coexisting hidden attractors were generated in the chaotic circuit, which was of great significance in engineering applications.

Keywords Dynamic analysis · Memristor · Chaotic circuit · Coexisting hidden attractors

1 Introduction

The first physical memristor was reported by the Hewlett-Packard Laboratory in 2008 [1]. It confirmed the existence of the fourth basic circuit element, that is memristor. The memristor have attracted the attention of many scholars for their potential applications in cellular neural network [2, 3], associative and non-associative learning [4, 5], circuit implemented electronic neurons [6], memory circuit [7], nonlinear oscillating circuits and other fields [8–11]. Because of the unique nonlinear characteristics of memristor, the chaotic circuit based on memristor has more abundant dynamic behaviors.

Since the chaos phenomenon was discovered in 1963 [12], many scholars have started to study chaos theory. Chaos circuit can be used as an important way to study chaos theory. Chua proposed the Chua’s circuit with a new type of strange attractor [13], which had a very simple structure and generated a variety of dynamic behaviors. Chua and Itoh proposed a new chaotic circuit which uses a memristor to replace the traditional Chua diode in Chua’s circuit [14]. Some interesting dynamic phenomena were also observed in the memristor chaotic circuit [15–18]. For example, multistability is a common phenomenon in many nonlinear dynamical systems [19–25]. In Ref. [22], a new two-memristor-based chaotic circuit was proposed and the coexistence of multiple attractors was analyzed. The multistability phenomenon of memristor-based chaotic circuits extremely relies on the initial conditions and the circuit parameters, which can produce some behaviors such as coexisting attractors and coexisting limit cycle.

Another kind of attractor newly proposed in recent years was called hidden attractor, whose basin does not intersect with the small neighborhood of any equilibrium points. The coexisting attractors and hidden attractors are of considerable importance in nonlinear dynamics and engineering applications [26–32]. In Ref. [30], a new three-dimensional quadratic two-wing hidden chaotic system is proposed, and fractional order multi-wing chaotic hidden attractors are generated in the system. In Ref. [31], the system has coexisting hidden attractors for some range of parameters.

In order to better apply the characteristics of physical memristor in chaotic circuits, this paper presents a fifth-order chaotic circuit based on the improved Sr$_{0.97}$Ba$_{0.03}$TiO$_{3-\delta}$ (SBT) memristor which was prepared in our laboratory [33], and the dynamic behaviors of the circuit system were ana-
analyzed through various methods. The rest of this paper is organized as follows. In Sect. 2, a modeling of memristor is established. In Sect. 3, the memristor chaotic circuit is designed. In Sect. 4, the stability of the system is analyzed, and the dynamics of dependence on the initial states are studied by means of numerical simulations. In particular, the coexisting hidden attractors can be found in this system. In addition, the influences of circuit parameters on dynamic behaviors of the system are studied in Sect. 5. The conclusions are given in Sect. 6.

2 Modeling of memristor

The Sr$_{0.97}$Ba$_{0.03}$TiO$_{3-\delta}$ (SBT) nanoscale memristor was fabricated using magnetron sputtering technology [33]. The I-V characteristic of the SBT memristor was tested and the measured data was obtained as shown in Fig. 1, which exhibits an obvious "8" hysteresis curve. It indicates that the SBT memristor can fit the basic requirements of the memristor characteristics well. The measured current $I$ and voltage $U$ were processed using the subsection-average method [34], the average current and average voltage after pre-processing are described in red line.

![Fig. 1 The measured $I-V$ curve (black line) and measured $I-V$ curve after pre-processing of the SBT memristor(red line)](image)

The charge $q$ and flux $\varphi$ was obtained by integrating the current and voltage data respectively, and the resulting discrete point plots of $q$ and $\varphi$ are shown in Fig. 2. The mathematical models for the memristor are commonly the cubic nonlinear model, the quadratic nonlinear model and the segmented linear model. In this paper, the cubic nonlinear model is used to fit the discrete point plots of $q$ and $\varphi$. The fitting results are shown in Fig. 2(blue line). Among them, the adopted cubic nonlinear model is

$$q(\varphi) = a\varphi + b\varphi^3$$

where $a > 0, b > 0$.

$$u(t) = \frac{d\varphi(t)}{dt}$$

$$i(t) = \frac{dq(t)}{dt}$$

$$W(\varphi) = \frac{i(t)}{u(t)}$$

Therefore, the memristive value $W(\varphi)$ of the memristor is:

$$W(\varphi) = \frac{dq(\varphi)}{d\varphi} = a + 3b\varphi^2$$

The fitting result was selected is:

$$q = 0.018\varphi + 0.026\varphi^3$$

The value of the memristive conductance is as follows:

$$W(\varphi) = 0.018 + 3 \times 0.026\varphi^2$$

This mathematical model for the SBT memristor was derived as:

$$\begin{cases}
i(t) = W(\varphi(t))u(t) \\
\frac{d\varphi(t)}{dt} = u(t) \\
\frac{dq(t)}{dt} = i(t) \\
W(\varphi(t)) = P + Q\varphi^2 = 0.018 + 3 \times 0.026\varphi^2 
\end{cases}$$

where, $P = 0.018S$, $Q = 3 \times 0.026S/Wb^2$, $i(t)$ is the current flowing through the memristor, $u(t)$ is the voltage across the memristor, $\varphi(t)$ is the magnetic flux of the memristor, and $W$ is the memristive conductance value of the memristor.
3 Design of memristor chaotic circuit

The circuit diagram of the SBT memristor chaotic circuit is depicted in Fig. 3.

![Fig. 3 The chaotic circuit based on memristor](image)

The circuit in the Fig. 3 consists of four linear capacitors \( C_1, C_2, C_3 \) and \( C_4 \), an operational amplifier A, six linear resistors \( R_1, R_2, R_3, R_4, R_5 \) and \( R_6 \), a linear conductance \( G \) and a nonlinear SBT memristor \( W(\varphi) \), in which \( C_1, C_2, C_3, R_1, R_2, R_3 \) constitute the double T network. In this circuit, an oscillating circuit is composed of the double T network and operational amplifier A, which generate the voltage oscillating signals. When the parameters are \( R_1=R_2=0.5R \), \( C_1=C_2=C \), \( C_3=2C \) and the magnification is \( A=1+R_3/R_6 \), the oscillation condition is satisfied and chaotic behavior may be generated. According to Ohm’s law and Kirchhoff’s law, the state equation of the circuit can be obtained as follows:

\[
\begin{align*}
\frac{dv_1}{dt} &= \frac{1}{C_1} \left( C_2 \frac{dv_2}{dt} + G_1 v_1 v_2 + v_3 + v_4 \right) - i_m(t) \\
\frac{dv_2}{dt} &= \frac{1}{C_2} \left( C_3 \frac{dv_3}{dt} + v_2 \right) - G_2 v_1 \\
\frac{dv_3}{dt} &= \frac{1}{C_3} \left( v_3 \right) - G(A v_1 + v_2) \frac{dv_4}{dt} \quad \text{where} \quad i_m(t) = (P + \frac{\varphi(t)^2}{2})(A v_1 + v_2) + v_3 + v_4.
\end{align*}
\]

(9)

where \( i_m(t) = (P + \frac{\varphi(t)^2}{2})(A v_1 + v_2) + v_3 + v_4 \), \( P = 0.0185 \), \( Q = 3 \times 0.0265/W \). When \( x=0.7, y=0.2, z=0.5, u=0.8, v_1=0.1 \), \( v_2=0.2 \), \( v_3=0.3 \), \( v_4=0.4 \), \( \alpha = 0.5 \), \( \beta = 1 \), \( \gamma = 0.5 \), \( \eta = 0.5 \), the circuit diagram is depicted in Fig. 3.

4 Dynamic analysis of the memristor circuit

4.1 Basic dynamic analysis of the system

The right side of Eq. 10 is equal to 0, then the equilibrium point of the system can be obtained as:

\[ E = \{(x,y,z,u,w)|x=y=z=u=0,w=c\} \quad (11) \]

where \( c \) is an arbitrary constant. All the points on the w-axis can be an equilibrium point. The Jacobian matrix evaluated at the equilibrium point is given as:

\[
J = \begin{bmatrix}
3\eta(\lambda - 1) & \gamma(\lambda - 1) & \gamma & 0 & 0 \\
\gamma(\lambda - 1) & \gamma(\lambda - 1) & \gamma & 0 & 0 \\
-\alpha & -\alpha & -\alpha & -\alpha & 0 \\
-\alpha & -\alpha & -\alpha & -\alpha & 0 \\
A & A & A & A & 0
\end{bmatrix}
\]

(12)

where \( H = W + G_0, W = 0.018 + 3 \times 0.026c^2, \alpha = 21.5, \beta = 0.667, \gamma = 1, \eta = 1, A = 1, G_0 = -0.6 \). The characteristic equation is consequently written as:

\[ |\lambda E - J| = \lambda^4 + a_1 \lambda^3 + a_2 \lambda^2 + a_3 \lambda + a_4 = 0 \quad (13) \]

The parameter \( w(c) = 0.018 + 3 \times 0.026c^2, \alpha = 21.5, \beta = 0.667, \gamma = 1, \eta = 1, A = 1, G_0 = -0.6 \) in Eq. 13:

\[
\begin{align*}
a_1 &= 1.716c^2 + 2.5365 \\
a_2 &= 2.3143c^2 - 1.9276 \\
a_3 &= 2.8736c^2 - 6.1007 \\
a_4 &= 2.7956c^2 - 6.5186
\end{align*}
\]

(14)

According to the Roux stability criterion, if the roots of the Eq. 14 satisfy that all the real parts of the real and complex roots are negative, the necessary and sufficient conditions are:

\[
H_k = \begin{bmatrix}
|a_1| & a_3 & 0 & 0 \\
1 & a_2 & a_4 & 0 \\
0 & a_1 & a_3 & 0 \\
0 & 1 & a_2 & a_4 \\
\end{bmatrix}
\]

(15)

where

\[
\begin{align*}
H_1 &= a_1 > 0 \\
H_2 &= a_1 a_2 - a_3 > 0 \\
H_3 &= a_1 (a_2 a_3 - a_1 a_4) - a_1^2 > 0 \\
H_4 &= a_4 H_3 > 0
\end{align*}
\]

(16)
By calculation, when $|c| > 1.527$, the system is in stable state, while the $|c| < 1.527$, the system equilibrium point is in an unstable state. And the system may exhibit chaos, limit cycle and other nonlinear dynamics behaviors near these unstable equilibrium points.

4.2 Effects of initial states on the dynamic characteristics of the system

4.2.1 Dynamic analysis of dependence on the initial state $w(0)$

When $\alpha = 21.5, \beta = 0.667, \gamma = 1, \eta = 1, A = 1, G_0 = -0.6$, the initial state is $(0.001, 0.001, 0.015, 0.001, w(0))$. The variation range of $w(0)$ is from -5 to 5. The Lyapunov exponents spectrum and bifurcation diagram of state variable $w$ is shown in Fig. 5. In order to see the changes of Lyapunov exponents more clearly, the four Lyapunov exponent are shown. The Lyapunov exponents spectrum of the system is highly consistent with the bifurcation diagram. With the increase of the initial state $w(0)$, the system presents a variety of dynamic behaviors. In the interval $[-5.00, -2.89]$ and $[2.84, 5.00]$, the system was in stable point state. In the interval $[2.88, 2.64], [2.42, 0.49], [0.55, 2.32]$ and $[2.63, 2.83]$, the system was in sink state. In the interval $[-0.48, -0.43]$, the system was in limit cycles state. In the intervals $[-2.63, -2.51], [-0.24, 0.41]$ and $[2.44, 2.62]$, the system was in double scroll chaotic attractor state. In the intervals $[-2.50, -2.43], [-0.42, -0.25], [0.42, 0.54]$ and $[2.33, 2.43]$, the system was in single scroll chaotic attractor state. The phase diagram of the initial state $w(0)$ in the $x - w$ plane at different special values are shown in Fig. 6. Fig. 6(a) is the limit cycle, Fig. 6(b) is the double scroll chaotic attractors, Fig. 6(c) is the single scroll chaotic attractor, Fig. 6(d) is the sinks.

The dynamic behavior of the initial state $w(0)$ of this chaotic system has coexistence behavior. For example, when the initial state is $(0.001, 0.001, 0.015, 0.001, \pm 0.45)$, the
Dynamics analysis of memristor chaotic circuit with coexisting hidden attractors

4.2.2 Dynamic analysis of dependence on the initial state $y(0)$

When $y(0)$ is taken as a state variable, and the other parameters of the system remain unchanged. The initial state is set to $(0.001, y(0), 0.015, 0.001, 0.01)$, the dynamic characteristics of $y(0)$ in the interval of $[-0.5, 0.5]$ are analyzed. The Lyapunov exponents spectrum and bifurcation diagram of state variable $y$ is shown in Fig. 9. The Lyapunov exponents spectrum of the system is highly consistent with the bifurcation diagram. When the system parameters remain unchanged and the initial state is $(0.001, ±0.298, 0.015, 0.001, 0.01)$, the coexistence of limit cycles exists in the system. The coexistence phase diagram and Poincaré section diagram are shown in Fig. 10. When the initial state is $(0.001, ±0.167, 0.015, 0.001, 0.01)$, the coexistence of single scroll chaotic attractors exists in the system. The coexistence phase diagram and Poincaré section diagram are shown in Fig. 11. When the initial state is $(0.001, ±0.142, 0.015, 0.001, 0.01)$, there is a phenomenon of coexistence of double chaotic attractors in the system. The coexistence phase diagram and the Poincaré section diagram are shown in Fig. 12. When the initial state is $(0.001, ±0.036, 0.015, 0.001, 0.01)$, there is a phenomenon of coexistence of double chaotic attractors in the system. The coexistence phase diagram and the Poincaré section diagram are shown in Fig. 13.
4.2.3 Dynamic analysis of dependence on the initial state $x(0), z(0), u(0)$

When the circuit element parameters are selected as $\alpha = 21.5$, $\beta = 0.667$, $\gamma = 1$, $\eta = 1$, $A = 1$, $G_0 = -0.6$, the dynamic characteristics of the initial state $x(0)$, $z(0)$ and $u(0)$ in the different interval are analyzed. The corresponding Lyapunov exponents diagrams and bifurcation diagrams are displayed in Figs. 14, 15 and 16. The minimum Lyapunov exponents are not depicted for clarity.

When the initial state $x(0), z(0)$ and $u(0)$ values are changed, the chaotic system will produce the coexistence phenomenon. The initial state parameters and the coexistence behavior are shown in Table 1, and the phase diagram and the Poincaré section diagram of the coexistence phenomenon are shown in Figs. 17, 18, 19, 20, 21 and 22.
4.3 The coexisting hidden attractors

The hidden attractors are difficult to find because both basins of attraction and the dimension of the attractor could be very small. Coexisting hidden attractors are coexistence of multiple hidden attractors, which was called hidden multi-stability. At present, there are few studies on the existence of coexisting hidden attractors in actual chaotic circuits. When
-2.63 < c < -2.43 or 2.33 < c < 2.62, the theoretical analysis in Sect. 4.1 shows that the equilibrium point is stable, the numerical simulation in Sect. 4.2.1 shows that the system is chaotic (Fig. 5), so the coexisting hidden attractors in blue line may exist in the system. For example, when \( w(0) = 2.5 \), the double scroll chaotic attractor is obtained (Fig. 25). The finite-time local Lyapunov exponents on the time interval \( t \in [0, 50] \) with \( w(0) = 2.5 \) are shown in Fig. 23, and they are calculated as \( LE_1 = 0.0128, LE_2 = 0.0199, LE_3 = -0.0176, LE_4 = -1.0213, LE_5 = -12.6051 \), which indicates that the memristor circuit system is chaotic. When \( w(0) = -2.5 \), the single scroll chaotic attractor in red line is obtained (Fig. 25). The finite-time local Lyapunov exponents on the time interval \( t \in [0, 50] \) with \( w(0) = -2.5 \) are shown in Fig. 24, and they are calculated as \( LE_1 = 0.0152, LE_2 = 0.0337, LE_3 = -0.0203, LE_4 = -1.0099, LE_5 = -11.9117 \), which indicates that the memristor circuit system is chaotic. Consequently, the coexisting hidden chaotic attractors exist in the system.

5 Effects of circuit parameters on the dynamic characteristics of the system

5.1 Influences of parameter \( \alpha \) on system dynamic behaviors

When parameter \( \alpha \) is in the range of \([0, 35]\) and initial values are \((0.001, 0.001, 0.015, 0.001, 0.01)\), the Lyapunov exponents spectrum and bifurcation diagram can be obtained in Fig. 26. In order to better observe the Lyapunov exponents of the chaos, the fifth Lyapunov exponential curve is not drawn. When \( \alpha = 5 \), the system exhibits limit cycle; when \( \alpha = 14 \), the system exhibits single scroll chaotic attractor; when \( \alpha = 30 \), the system exhibits double scroll chaotic attractor. The phase diagram and Poincare section diagram of the dynamic behaviors are shown in Figs. 27, 28 and 29.

5.2 Influences of other parameters on system dynamic behaviors

The initial states are set as \((0.001, 0.001, 0.015, 0.001, 0.01)\), and the dynamics of the circuit system with the variation in the circuit parameters \( \beta, \gamma \) and \( \eta \), and are depicted in
Dynamics analysis of memristor chaotic circuit with coexisting hidden attractors

Table 2. Dynamic behaviors of the circuit parameters $\beta$, $\gamma$ and $\eta$ in different intervals

| The circuit parameter | Interval          | Dynamics             |
|-----------------------|-------------------|----------------------|
| $\beta$               | (0.00, 0.62)      | Single-scroll attractors |
|                       | (0.63, 0.82)      | Double-scroll attractors |
|                       | (0.83, 2.00)      | Limit cycle           |
| $\gamma$              | (0.00, 1.44)      | Double-scroll attractors |
|                       | (1.45, 2.08)      | Single-scroll attractors |
|                       | (2.09, 10.00)     | Limit cycle           |
| $\eta$                | (0.00, 0.87)      | Sink                 |
|                       | (0.88, 1.44)      | Double-scroll attractors |
|                       | (1.45, 1.62)      | Single-scroll attractors |
|                       | (1.63, 2.00)      | Limit cycle           |

6 Conclusion

In the paper, the cubic memristor model of SBT memristor is established, and the single-memristor fifth-order chaotic circuit is designed. The equilibrium stability of the circuit is analyzed by numerical calculation method, and the dynamic behaviors of the system with the initial states and circuit
parameters is studied by using phase diagram, Lyapunov exponents spectra, bifurcation diagrams and Poincaré maps. The results show that the system exhibits complex dynamic behaviors such as stable points, chaotic attractors, limit cycles and a variety of coexistence phenomena. Particularly, the system has a special dynamic behavior of coexisting hidden attractors. All the results will contribute to the practical application of chaotic circuits.
