The \( M \)-relative distance, denoted by \( \rho_M \), is a generalization of the \( p \)-relative distance, which was introduced in [10]. We establish necessary and sufficient conditions under which \( \rho_M \) is a metric. In two special cases we derive complete characterizations of the metric. We also present a way of extending the results to metrics sensitive to the domain in which they are defined, thus finding some connections to previously studied metrics.

An auxiliary result of independent interest is an inequality related to Pittenger’s inequality in Section 4.

**Key Words:** Relative metrics, weighted metrics, Pittenger’s inequality

**1. INTRODUCTION AND MAIN RESULTS**

In this section we introduce the problem of this study and state two useful corollaries of the core results. The core results themselves are stated only in Section 3, since they require somewhat more notation. The topic of this paper are \( M \)-relative distances, which are functions of the form

\[
\rho_M(x, y) := \frac{|x - y|}{M(|x|, |y|)},
\]

where \( M : \mathbb{R}^+ \times \mathbb{R}^+ \to \mathbb{R}^+ \) is a symmetric function satisfying \( M(|x|, |y|) > 0 \) if \( |x||y| > 0 \), and \( x \) and \( y \) are in some normed space (note that \( \mathbb{R}^+ \) denotes \([0, \infty)\)). We are interested in knowing when \( \rho_M \) is a metric, in which case it is called the \( M \)-relative metric.

* Supported in part by the Academy of Finland and the Finnish Academy of Science and Letters (Viljo, Yrjö and Kalle Väisälä’s Fund)
The first special case that we consider is when $M$ equals a power of the power mean, 

$$M = A_p^q,$$

where

$$A_p(x,y) := ((x^p + y^p)/2)^{1/p}, \quad A_0(x,y) := (xy)^{1/2},$$

$$A_{-\infty}(x,y) := \min\{x,y\} \quad \text{and} \quad A_{\infty}(x,y) := \max\{x,y\},$$

for $p \in \mathbb{R} \setminus \{0\}$ and $x, y \in \mathbb{R}^+$, see also Definition 4.1. In this case we denote $\rho_M$ by $\rho_{p,q}$ and call it the $(p,q)$–relative distance. The $(p,1)$–relative distance was introduced by Ren–Cang Li [10], who proved that it is a metric in $\mathbb{R}$ for $p \geq 1$ and conjectured it to be one in $\mathbb{C}$ as well. Later, the $(p,1)$–relative distance was shown to be a metric in $\mathbb{C}$ for $p = \infty$ by David Day [7] and for $p \in [1, \infty)$ by Anders Barrlund [4]. These investigations provided the starting point for the present paper and the following theorem contains their results as special cases:

**Theorem 1.1.** Let $q \neq 0$. The $(p,q)$–relative distance,

$$\rho_{p,q}(x,y) = \frac{|x - y|}{A_p(|x|,|y|)^q},$$

is a metric in $\mathbb{R}^n$ if and only if $0 < q \leq 1$ and $p \geq \max\{1 - q, (2 - q)/3\}$.

**Remark 1. 1.** As is done in the previously cited papers, we define $\rho_{p,q}(0,0) = 0$ even though the expression for $\rho_{p,q}$ equals $0/0$ in this case.

The second special case that we study in depth is $M(x,y) = f(x)f(y)$, where $f: \mathbb{R}^+ \to (0, \infty)$.

**Theorem 1.2.** Let $f: \mathbb{R}^+ \to (0, \infty)$ and $M(x,y) = f(x)f(y)$. Then $\rho_M$ is a metric in $\mathbb{R}^n$ if and only if

(i) $f$ is increasing,

(ii) $f(x)/x$ is decreasing for $x > 0$ and

(iii) $f$ is convex.

(There are non-trivial functions which satisfy conditions (i)-(iii), for instance the function $f(x) := (1 + x^p)^{1/p}$ for $p \geq 1$.)

In the fourth section we derive an inequality of the Stolarsky mean related to Pittenger’s inequality which is of independent interest. In the sixth section, we present a scheme for extending the results of this investigation.
to metrics sensitive to the domain in which they are defined. This provides connections with previously studied metrics.

This paper is the first of two papers dealing with the $M$-relative distance. In the second paper, [8], we will consider various properties of the $M$-relative metric. In particular, isometries and quasiconvexity of $\rho_M$ are studied there.

2. PRELIMINARIES

2.1. Metric and normed spaces

By a metric on a set $X$ we mean a function $\rho: X \times X \to \mathbb{R}^+$ which satisfies

1. $\rho(x, y)$ is symmetric,
2. $\rho(x, y) \geq 0$ and $\rho(x, y) = 0$ if and only if $x = y$ and
3. $\rho(x, y) \leq \rho(x, z) + \rho(z, y)$ for all $x, y, z \in X$.

A function which satisfies Condition 2. is known as positive definite; the inequality in Condition 3. is known as the triangle inequality.

By a normed space we mean a vector space $X$ with a function $|\cdot|: X \to \mathbb{R}^+$ which satisfies

1. $|ax| = |a||x|$ for $x \in X$ and $a \in \mathbb{R}$,
2. $|x| = 0$ if and only if $x = 0$ and
3. $|x + y| \leq |x| + |y|$ for all $x, y \in X$.

2.2. Ptolemaic spaces

A metric space $(X, d)$ is called Ptolemaic if

$$d(z, w)d(x, y) \leq d(y, w)d(x, z) + d(x, w)d(y, z) \quad (1)$$

holds for every $x, y, z, w \in X$ (for background information on Ptolemy’s inequality, see e. g. [5, 10.9.2]). A normed space $(X, |\cdot|)$ is Ptolemaic if the metric space $(X, d)$ is Ptolemaic, where $d(x, y) = |x - y|$. The following lemma provides a characterization of Ptolemaic normed spaces.

**Lemma 2.1.** ([2, 6.14]) A normed space is Ptolemaic if and only if it is an inner product space.

Since the Ptolemaic inequality, (1), with $d$ equal to the Euclidean metric can be expressed in terms of cross-ratios (see (13), in Section 6) it follows directly that $(\mathbb{R}^n, q)$ is a Ptolemaic metric space, where $q$ denotes the chordal metric,

$$q(x, y) := \frac{|x - y|}{\sqrt{1 + |x|^2\sqrt{1 + |y|^2}}}, \quad q(x, \infty) := \frac{1}{\sqrt{1 + |x|^2}}. \quad (2)$$
with \( x, y \in \mathbb{R}^n \). The following lemma provides yet another example of a Ptolemaic space.

**Lemma 2.2.** [9] Hyperbolic space is Ptolemaic.

Thus in particular the Poincaré Model of the hyperbolic metric, \((B^n, \rho)\), is Ptolemaic. This metric will be considered in section 5 of the sequel of this investigation, [8].

### 2.3. Real-valued functions

An increasing function \( f : \mathbb{R}^+ \to \mathbb{R}^+ \) is said to be *moderately increasing* (or shorter, to be MI) if \( f(t)/t \) is decreasing on \((0, \infty)\). A function \( P : \mathbb{R}^+ \times \mathbb{R}^+ \to \mathbb{R}^+ \) is MI if \( P(x, \cdot) \) and \( P(\cdot, x) \) are MI for every \( x \in (0, \infty) \). Equivalently, if \( P \) is symmetric and \( P \not\equiv 0 \) then \( P \) is MI if and only if \( P(x, y) > 0 \) and

\[
\frac{z}{x} \leq \frac{P(z, y)}{P(x, y)} \leq 1 \leq \frac{P(x, z)}{P(x, y)} \leq \frac{z}{y}
\]

for all \( 0 < y \leq z \leq x \).

The next lemma shows why we have assumed that \( M(x, y) > 0 \) for \( xy > 0 \).

**Lemma 2.3.** Let \( P : \mathbb{R}^+ \times \mathbb{R}^+ \to \mathbb{R}^+ \) be symmetric and MI. Then exactly one of the following conditions holds:

1. \( P \equiv 0 \),
2. \( P(x, y) = 0 \) if and only if \( x = 0 \) or \( y = 0 \),
3. \( P(x, y) = 0 \) if and only if \( x = 0 \) and \( y = 0 \) or
4. \( P(x, y) > 0 \) for every \( x, y \in \mathbb{R}^+ \).

**Proof.** Suppose \( P \not\equiv 0 \). Let \( x, y \in (0, \infty) \) be such that \( P(x, y) > 0 \). Then

\[
P(z, w) \geq \min \{1, z/x\} \min \{1, w/y\} P(x, y) > 0
\]

for every \( z, w \in (0, \infty) \). Let then \( x \in (0, \infty) \) be such that \( P(x, 0) > 0 \). Then \( P(z, 0) \geq \min \{1, z/x\} P(x, 0) > 0 \) for every \( z \in (0, \infty) \). Finally, if \( P(0, 0) > 0 \) then \( P(x, y) > 0 \) for every \( x, y \in \mathbb{R}^+ \) since \( P \) is increasing.

**Lemma 2.4.** Let \( P : \mathbb{R}^+ \times \mathbb{R}^+ \to \mathbb{R}^+ \) be symmetric and MI. Then \( P \) is continuous in \((0, \infty) \times (0, \infty)\).
Proof. Fix points \(x, y \in (0, \infty)\). Since \(P\) is MI we have
\[
\min\{1, z/x\} \min\{1, w/y\} P(z, w) \leq P(x, y) \leq \max\{1, x/z\} \max\{1, y/w\} P(z, w),
\]
for \(w, z > 0\), from which it follows that \(|P(x, y) - P(z, w)|\) is bounded from above by
\[
\max\{1 - \min\{1, z/x\} \min\{1, w/y\}, \max\{1, x/z\} \max\{1, y/w\} - 1\},
\]
and so the continuity is clear.

A function \(P: \mathbb{R}^+ \times \mathbb{R}^+ \to \mathbb{R}^+\) is said to be \(\alpha\)-homogeneous, \(\alpha > 0\), if
\[
P(sx, sy) = s^\alpha P(x, y)
\]
for every \(x, y, s \in \mathbb{R}^+\). A 1–homogeneous function is called homogeneous.

**Lemma 2.5.** Let \(P: \mathbb{R}^+ \times \mathbb{R}^+ \to \mathbb{R}^+\) be symmetric, increasing and \(\alpha\)-homogeneous for some \(0 < \alpha \leq 1\). Then \(P\) is MI.

Proof. Let \(x \geq z \geq y > 0\). The relations
\[
xP(z, y) = xz^\alpha P(1, y/z) \geq zx^\alpha P(1, y/x) = zP(x, y)
\]
and
\[
yP(x, z) = yz^\alpha P(x/z, 1) \leq yz^\alpha P(x/y, 1) = zP(x, y)
\]
imply that \(P\) is MI.

### 2.4. Conventions

Recall from the introduction that \(M: \mathbb{R}^+ \times \mathbb{R}^+ \to \mathbb{R}^+\) is a symmetric function which satisfies \(M(x, y) > 0\) if \(xy > 0\). Throughout this paper we will use the short-hand notation \(M(x, y) := M(|x|, |y|)\) in the case when \(x, y \in \mathbb{X}\). We will denote by \(\mathbb{X}\) a Ptolemaic normed space which is non-degenerate, i.e. \(\mathbb{X}\) non-empty and \(\mathbb{X} \neq \{0\}\). Moreover, if \(M(0, 0) = 0\) then “\(\rho_M\) is a metric in \(\mathbb{X}\)” is understood to mean that \(\rho_M\) is a metric in \(\mathbb{X} \setminus \{0\}\) (similarly for \(\mathbb{R}\) or \(\mathbb{R}^n\) in place of \(\mathbb{X}\)).

### 3. THE M-RELATIVE METRIC

**Theorem 3.1.** Let \(M\) be MI. Then \(\rho_M\) is a metric in \(\mathbb{X}\) if and only if it is a metric in \(\mathbb{R}\).
Proof. Since in all cases it is clear that $\rho_M$ is symmetric and positive definite, when we want to prove that $\rho_M$ is a metric we need to be concerned only with the triangle inequality. The necessity of the condition is clear; just restrict the metric to a one-dimensional subspace of $X$ which is isometric to $\mathbb{R}$.

We will consider a triangle inequality of the form $\rho_M(x, y) \leq \rho_M(x, z) + \rho_M(z, y)$. Let $x, y, z \in X$ be such that $M(x, y), M(x, z), M(z, y) > 0$. Since $M$ is increasing, the case $z = 0$ is trivial and we may thus assume $|z| > 0$. For sufficiency we use the triangle inequality for the norm $\| \cdot \|$ and Ptolemy’s inequality with $w = 0$ to estimate $|x - y|$ in the left hand side of $\rho_M(x, y) \leq \rho_M(x, z) + \rho_M(z, y)$.

We get the following two sufficient conditions for $\rho_M$ being a metric:

$$|x - z|(1/M(x, z) - 1/M(x, y)) + |z - y|(1/M(z, y) - 1/M(x, y)) \geq 0,$$

and

$$|x - y| \left( \frac{1}{M(x, z)} - \frac{|y|}{|z|M(x, y)} \right) + |z - y| \left( \frac{1}{M(z, y)} - \frac{|x|}{|z|M(x, y)} \right) \geq 0.$$

If $|z| \leq \min\{|x|, |y|\}$, the first inequality holds since $M$ is increasing. The second one holds if $|z| \geq \max\{|x|, |y|\}$ since $f$ is MI. By symmetry, we may therefore assume that $|x| > |z| > |y|$. Then $|x - z|$ has a negative coefficient in the first inequality, whereas $|z - y|$ has a positive one. The roles are interchanged in the second inequality. Thus we get two sufficient conditions:

$$\frac{|z - y|}{|x - z|} \geq \frac{1/M(x, y) - 1/M(x, z)}{1/M(z, y) - 1/M(x, y)}$$

and

$$\frac{|z - y|}{|x - z|} \leq \frac{1/M(x, z) - |y|/(|z|M(x, y))}{|x|/(|z|M(x, y)) - 1/M(z, y)}.$$

Now if

$$\frac{1/M(x, z) - |y|/(|z|M(x, y))}{|x|/(|z|M(x, y)) - 1/M(z, y)} \geq \frac{1/M(x, y) - 1/M(x, z)}{1/M(z, y) - 1/M(x, y)},$$

then certainly at least one of the above sufficient conditions holds. Rearranging the last inequality gives

$$\frac{|x - |y|}{M(x, y)} \leq \frac{|x| - |z|}{M(x, z)} + \frac{|z| - |y|}{M(z, y)},$$

the triangle inequality for $\rho_M$ in $\mathbb{R}$. Thus if $\rho_M$ is a metric in $\mathbb{R}$, it is a metric in $X$, so the condition is also sufficient. □
Remark 3.1. In the proof of Theorem 3.1 we actually proved that the $\mathbb{R}$ in the statement of the theorem could be replaced by $\mathbb{R}^+$. Since the latter in not a vector space we prefer the above statement. Nevertheless, in proofs it will actually suffice to show that $\rho_M$ satisfies the triangle inequality for $0 < y < z < x$, since the other cases follow from the MI condition as was seen in the proof.

We may define $\rho_M$ in metric spaces as well: Let $a \in X$ be an arbitrary fixed point. Then we define

$$\rho_M(x, y) := \frac{d(x, y)}{M(d(x, a), d(y, a))}.$$  

(As with $X$, if $M(0, 0) = 0$ then we consider whether $\rho_M$ is a metric in $X \setminus \{a\}$.)

Corollary 3.1. Let $M$ be MI and let $X$ be a Ptolemaic metric space and let $a \in X$ be an arbitrary fixed point. Then $\rho_M$ is a metric in $X$ if it is a metric in $\mathbb{R}$.

Proof. As in the previous proof we conclude that

$$\frac{|d(x, a) - d(y, a)|}{M(d(x, a), d(y, a))} \leq \frac{|d(x, a) - d(z, a)|}{M(d(x, a), d(z, a))} + \frac{|d(z, a) - d(y, a)|}{M(d(z, a), d(y, a))}$$

is a sufficient condition for $\rho_M$ being a metric in $X$ (this corresponds to (3)). However, since $d(x, a)$, $d(y, a)$ and $d(z, a)$ are all just real numbers this inequality follows from the triangle inequality of $\rho_M$ in $\mathbb{R}$.

Corollary 3.2. Let $M$ be MI. Then each of $\log\{1+\rho_M(x, y)\}$, $\cosh\{1+\rho_M(x, y)\}$ and $\arcsinh\rho_M(x, y)$ is a metric in $X$ if and only if it is a metric in $\mathbb{R}$.

Proof. Denote by $f$ the function $e^x - 1$, $\cosh|x| - 1$ or $\sinh x$ so that the distance under consideration equals $f^{-1}(\rho_M)$. Applying $f$ to both sides of the triangle inequality of $f^{-1}(\rho_M)$ gives

$$\rho_M(x, y) \leq \rho_M(x, z) + \rho_M(z, y) + g(f^{-1}(\rho_M(x, z)), f^{-1}(\rho_M(z, y))),$$

(4)

where $g(x, y) := f(x + y) - f(x) - f(y)$. Proceeding as in the proof of Theorem 3.1, we conclude that (4) follows from

$$\frac{|x| - |y|}{M(x, y)} \leq \frac{|x| - |z|}{M(x, z)} + \frac{|z| - |y|}{M(z, y)}$$

(5)
\[ + \frac{|x|-|z|}{|x|-|z|} g \left( f^{-1} \left( \frac{|x|-|z|}{M(x,z)} \right), f^{-1} \left( \frac{|z|-|y|}{M(z,y)} \right) \right). \]

We may replace the term \((|x|-|z|)/|x|-|z|\) by \((|z|-|y|)/|z|-|y|\) by considering the ratio \(|x|-|z|/|x|-|z|\) instead of \(|x|-|z|/|x|-|z|\) in the proof of Theorem 3.1. Since both conditions are sufficient we may write it as one condition by using the constant

\[ m := \max \left( \frac{|x|-|z|}{|x|-|z|}, \frac{|z|-|y|}{|z|-|y|} \right) \geq \sqrt{\frac{|x|-|z|}{|x|-|z|} \cdot \frac{|z|-|y|}{|z|-|y|}}. \tag{6} \]

Then (5) follows from the triangle inequality in \(\mathbb{R}\) if

\[ g \left( f^{-1} \left( \frac{|x|-|z|}{M(x,z)} \right), f^{-1} \left( \frac{|z|-|y|}{M(z,y)} \right) \right) \leq \]

\[ \leq m g \left( f^{-1} \left( \frac{|x|-|z|}{M(x,z)} \right), f^{-1} \left( \frac{|z|-|y|}{M(z,y)} \right) \right). \]

For \(f\) equal to \(e^x - 1, \cosh\{x\} - 1\) and \(\sinh x\) we see that \(g(f^{-1}(a), f^{-1}(b))\) equals \(ab, ab + \sqrt{a^2 + 2a\sqrt{b^2 + 2b}}\) and \(a(\sqrt{1+b^2} - 1) + b(\sqrt{1+a^2} - 1)\), respectively. Now we see that each of these terms has either a factor \(a, b\) or \(\sqrt{ab}\), hence by choosing a suitable term in \(m\) or the lower bound from (6) using \(|x|-|y| \geq |x|-|y|\) etc. the inequality follows.

The reason for considering \(\log\{1 + \rho_M(x,y)\}, \arccosh\{1 + \rho_M(x,y)\}\) and \(\arcsinh\rho_M(x,y)\) is that these metric transformations (see the next remark) are well-known and have been applied in various other areas, notably in generalizing the hyperbolic metric (see [8, Section 5]).

**Remark 3.** (i) Let \(X\) be a set and \(d: X \times X \to \mathbb{R}^+\) be a function. Denote

- A: \(d\) is a metric in \(X\),
- B: \(\log\{1 + d\}\) is a metric in \(X\),
- C: \(\arcsinh\{d\}\) is a metric in \(X\) and
- D: \(\arccosh\{1 + d\}\) is a metric in \(X\).

Then \(A \Rightarrow B \Rightarrow D\) and \(A \Rightarrow C \Rightarrow D\), but \(B\) and \(C\) are not comparable, in the sense that there exists a \(d\) such that \(B\) is a metric but \(C\) is not and the other way around. These claims are easily proved by applying inverse functions (that is \(e^x, \sinh x\) and \(\cosh x\)) to the triangle inequality. For instance, to prove \(A \Rightarrow B\) we see that the triangle inequality for the \(\log\{1 + d\}\) variant transforms into \(1 + d(x,y) \leq (1 + d(x,z))(1 + d(z,y))\) which is equivalent to \(d(x,y) \leq d(x,z) + d(z,y) + d(x,z)d(z,y)\).
(ii) Another passing remark is that if \( f \) is subadditive and \( d \) is a metric then \( f \circ d \) is a metric as well. Since an MI function is subadditive, as noted in [3, Remark 7.42], it follows, that the composition of an MI function with a metric is again a metric.

**Definition 3.1.** A function \( P: \mathbb{R}^+ \times \mathbb{R}^+ \to \mathbb{R}^+ \) that satisfies
\[
\max\{x^\alpha, y^\alpha\} \geq P(x, y) \geq \min\{x^\alpha, y^\alpha\}.
\]
is called an \( \alpha \)--quasimean, \( \alpha > 0 \). A 1--quasimean is called a mean. We define the trace of \( P \) by \( t_P(x) := P(x, 1) \) for \( x \in [1, \infty) \). If \( P \) is an \( \alpha \)--homogeneous symmetric quasimean then
\[
P(x, y) = y^\alpha P(x/y, 1) = y^\alpha t_P(x/y)
\]
for \( x \geq y > 0 \), so that \( t_P \) determines \( P \) uniquely in this case.

If we normalize an \( \alpha \)--homogeneous increasing symmetric function \( P \) so that \( P(1, 1) = 1 \) then \( P \) is an \( \alpha \)--quasimean.

**Definition 3.2.** We define a partial order on the set of \( \alpha \)--quasimeans by \( P \preceq N \) if \( t_P(x)/t_N(x) \) is increasing.

Note that \( P \succeq N \) implies that \( t_P(x) \geq t_N(x) \), since \( t_P(1) = t_N(1) = 1 \) by definition.

We will need the following family of quasimeans, related to the Stolarsky mean (see Remark 3.3),
\[
S_p(x, y) := (1 - p)\frac{x - y}{x^{1-p} - y^{1-p}}, \quad S_p(x, x) = x^p, \quad 0 < p < 1,
\]
\[
S_1(x, y) := L(x, y) := \frac{x - y}{\log x - \log y}, \quad S_1(x, x) = x,
\]
defined for \( x, y \in \mathbb{R}^+, \ x \neq y \). Note that \( S_1(x, y) = \lim_{y \to 0} S_1(x, y) = 0 \) equals the classical logarithmic mean, \( L \), with \( S_1(x, 0) := 0 \).

**Lemma 3.1.** Let \( 0 < \alpha \leq 1 \) and \( M \) be increasing and \( \alpha \)--homogeneous.

I. If \( M \succeq S_\alpha \) then \( \rho_M \) is a metric in \( \mathbb{X} \).

II. If \( \rho_M \) is a metric in \( \mathbb{X} \), then \( M(x, y) \geq S_\alpha(x, y) \) for \( x, y \in \mathbb{R}^+ \) and
\[
\frac{M(x, 1)}{S_\alpha(x, 1)} \leq \frac{M(x^2, 1)}{S_\alpha(x^2, 1)}.
\]
for \( x \geq 1 \).

\textit{Proof.} By Lemma 2.5 \( M \) is MI. By Remark 3.1 it suffices to show that the triangle inequality holds in \( \mathbb{R}^+ \) with \( y < z < x \). We will consider the cases \( \alpha = 1 \) and \( \alpha < 1 \) separately.

If \( \alpha = 1 \), set \( g(x) := t_M(x)/t_L(x) \) for \( x \in [1, \infty) \). Since \( M(x, 0) = xM(1, 0) \) and \( M(z, 0) =zM(1, 0) \) the triangle inequality is trivial if \( y = 0 \), so we may assume that \( y > 0 \). Then the triangle inequality for \( \rho_M \) becomes

\[
\log st \leq \log s + \log t, \tag{7}
\]

where \( s = x/z \) and \( t = z/y \). Since \( \log st = \log s + \log t \), it is clear that this inequality holds if \( g \) is increasing, hence \( L \preceq M \) is a sufficient condition.

Assume, conversely, that \( \rho_M \) is a metric. Let \( 0 < y = x_0 < x_1 < \ldots < x_{n+1} = x \) (note that \( X \) has a subspace isomorphic to \( \mathbb{R} \)). Using \( M(x_i, x_{i+1}) \geq x_i \) we conclude that

\[
\frac{x - y}{M(x, y)} \leq \sum_{i=0}^{n} \frac{x_{i+1} - x_i}{M(x_i, x_{i+1})} \leq \sum_{i=0}^{n} \frac{x_{i+1} - x_i}{x_i},
\]

and it follows by taking the limit that

\[
\frac{x - y}{M(x, y)} \leq \int_y^x \frac{dz}{z} = \log \frac{x}{y}
\]

and hence \( L(x, y) \leq M(x, y) \).

Assume now that \( \alpha < 1 \) and let \( g(x) := t_M(x)/t_{S_\alpha}(x) \) for \( x \in [1, \infty) \). If \( y = 0 \) then the triangle inequality takes on the form

\[
\frac{x^{1-\alpha} - z^{1-\alpha}}{M(0, 1)} \leq \frac{x - z}{M(x, z)}.
\]

This is equivalent to

\[
g(x/z) \leq M(1, 0)/(1 - \alpha) = \lim_{s \to \infty} g(s)
\]

and hence follows, since \( g \) is increasing. Assume then that \( y > 0 \). Then the triangle inequality becomes

\[
\frac{x^{1-\alpha} - y^{1-\alpha}}{g(x/y)} \leq \frac{x^{1-\alpha} - z^{1-\alpha}}{g(x/z)} + \frac{z^{1-\alpha} - y^{1-\alpha}}{g(z/y)},
\]
where \( y < z < x \). Clearly this holds if \( g \) is increasing. The necessary conditions \( g(x) \geq 1 \) and \( g(x) \leq g(x^2) \) follow as above.

**Remark 3. 3.** For \( p \in (0, 1] \) and \( x, y \in \mathbb{R}^+ \) the quasimean \( S_p \) defined above is related to Stolarsky’s mean \( S_{1-p} \) by

\[
S_t(x, y) := \left( \frac{x^p - y^p}{p(x - y)} \right)^{1/(1-p)} = S_{1-p}(x, y)^{1/(1-p)},
\]

for \( 0 < p < 1 \) and \( Sl_0(x, y) := L(x, y) \). Note that the Stolarsky mean can also be defined for \( p \not\in [0, 1) \), however, we will not make use of this fact. The reader is referred to [13] for more information on the Stolarsky mean.

**Remark 3. 4.** Strong inequalities, i.e. inequalities of the type \( A \succeq B \), have been recently proved by Alzer for polygamma function [1]. Also, although not stating so, some people have proved strong inequalities when what they actually wanted to get at was just an ordinary inequality. Thus for instance Vamanamurthy and Vuorinen proved that \( \text{AGM} \succeq L \), where \( \text{AGM} \) denotes the arithmetic-geometric mean, see [14]. Thus there are potentially many other forms which can be shown to be metrics by means of Lemma 3.1.

### 4. STOLARSKY MEAN INEQUALITIES

**Definition 4.1.** Let \( x, y \geq 0 \). We define the power-mean of order \( p \) by

\[
A_p(x, y) := \left( \frac{x^p + y^p}{2} \right)^{1/p}
\]

for \( p \in \mathbb{R} \setminus \{0\} \) and additionally

\[
A_{-\infty}(x, y) = \min\{x, y\}, \quad A_0(x, y) := \sqrt{xy} \quad \text{and} \quad A_\infty(x, y) = \max\{x, y\}.
\]

Also observe the convention \( A_p(x, 0) = 0 \) for \( p \leq 0 \).

In order to use the results of the previous section, we need to investigate the partial order \( \preceq \) from Definition 3.2. The next result is an improvement of a result of Tung–Po Lin in [11] which states that \( L \preceq A_p \) if and only if \( p \geq 1/3 \). Lin’s result is implied by Lemma 4.1, since \( \preceq \) implies \( \preceq \).
Lemma 4.1. \( L \preceq A_p \) if and only if \( p \in [1/3, \infty] \).

Proof. Denote \( t_{A_p} \) by \( t_p \). Since \( t_L, t_p \in C^1 \), \( L \preceq A_p \) is equivalent to
\[
\frac{d \log t_L(x)}{dx} \leq \frac{\partial \log t_p(x)}{\partial x}. \tag{8}
\]

Since
\[
\frac{\partial^2 \log t_p(x)}{\partial p \partial x} = \frac{x^{p-1} \log x}{(x^p + 1)^2} > 0,
\]
(8) holds for \( p \geq 1/3 \) if it holds for \( p = 1/3 \). Calculating (8) for \( p = 1/3 \) gives
\[
\int \frac{1}{x-1} - \frac{1}{x \log x} \leq \frac{1}{x + x^{2/3}}.
\]
Substituting \( x = y^3 \) and rearranging gives
\[
3 \log y \leq (y^3 - 1)(1 + 1/y)/(y^2 + 1).
\]
Note that equality holds for \( y = 1 \). It suffices to show that the derivative of the right hand side is greater than that of the left hand side. Differentiating and rearranging leads to
\[
y^6 - 3y^5 + 3y^4 - 2y^3 + 3y^2 - 3y + 1 \geq 0,
\]
which is equivalent to the tautology \((y-1)^4(y^2 + y + 1) \geq 0\).

Since “\( \preceq \)” implies “\( \leq \)” , it follows from [11] that \( L \not\preceq A_p \) for \( p < 1/3 \). \( \blacksquare \)

The previous lemma can be generalized to the quasimean case:

Lemma 4.2. For \( 0 < q \leq 1 \), \( A^q_p \succeq S_q \) if and only if \( p \geq \max\{1 - q, (2 - q)/3\} \).

Proof. The claim follows from the previous lemma for \( q = 1 \). For \( 0 < q < 1 \) we need to show that \( g(x) := (x^p + 1)^{q/p}(x^{1-q} - 1)/(x - 1) \) is increasing for all \( x \geq 1 \) and \( p \geq \max\{1 - q, (2 - q)/3\} \). This is equivalent to showing that the logarithmic derivative of \( g \) is non-negative for \( x \geq 1 \), i.e. that \( g'(x)/g(x) \geq 0 \). Rearranging the terms, we see that this is equivalent to
\[
q(x^p + x^{1-q})(x - 1) \leq (x - x^{1-q})(x^p + 1). \tag{9}
\]
Letting $x \to \infty$ and comparing exponents, we see that this can hold only if $p \geq 1 - q$. The other bound on $p$ comes from $x \to 1^+$, however, only after some work.

As $x \to 1^+$ ($x$ tends to 1 from above), both sides of (9) tend to 0. Their first derivatives both tend to $2q$ and the second derivatives to $2q(p + 1 - q)$. Only in the third derivatives is there a difference, the left hand side tending to $3q(p(p - 1) + q(1 - q))$ and the right hand side to $3p(p - 1)q + 2p(1 - q)q - 2q(1 - q^2) + p(1 - q)q$. Thus the right hand side of (9) is greater than or equal to the left at $1^+$ only if $3p \geq 2 - q$.

We still need to check the sufficiency of the condition on $p$. Since $A_{p} \geq A_{s}$ for $p \geq s$, it is enough to check $p = \max\{1 - q, (2 - q)/3\}$. For $q \leq 1/2$ set $q = 1 - p$ in (9). This gives $(2p - 1)x^p(x - 1) + x - x^{2p} \geq 0$. Since the second derivative of this function is positive, the inequality follows easily.

Now set $q = 2 - 3p$ in (9). Dividing both sides by $x^p$ and rearranging gives

\[
g_p(x) := (3p - 1)(x - x^{2p - 1}) + (2 - 3p)(1 - x^2)p - x^{3p - 1} + x^{1 - p} \geq 0.
\]

Since $g_{1/3}(x) = 1 - x^{2/3} - 1 + x^{2/3} = 0$ and $g_{1/2}(x) = (x - 1)/2 + (1 - x)/2 - x^{1/2} + x^{1/2} = 0$, the previous inequality follows if we show that $\partial^2 g_p(x)/\partial p^2 \leq 0$ for every $x$. Now

\[
\frac{\partial^2 g_p(x)}{\partial p^2} = 12(x^{2p} - x^{2p - 1}) \log x
\]

\[-(4(3p - 1)x^{2p - 1} + 4(2 - 3p)x^{2p} - x^{1 - p} + 9x^{3p - 1}) \log^2 x,
\]

and hence $\partial^2 g_p(x)/\partial p^2 \leq 0$ is equivalent to (we divide by $x^{2p}$)

\[
12(1 - 1/x) \leq (9x^{p - 1} - x^{1 - 3p} + 4(2 - 3p) + 4(3p - 1)/x) \log x. \quad (10)
\]

We will show that inequality holds for $p = 1/3$ and $p = 1/2$ and that the right hand side is concave in $p$. Hence the inequality holds for $1/3 < p < 1/2$ as well.

For $p = 1/3$, (10) is equivalent to

\[
x(3x^{-2/3} + 1) \log x \geq 4(x - 1).
\]

Since

\[
\log x \geq 4 \frac{x - 1}{x + 3x^{1/3}}
\]

holds for $x = 1$, it suffices to show that the derivative of the left hand side is greater than that of the right hand side:

\[
\frac{1}{x} \geq 4 \frac{x + 3x^{1/3} - (x - 1)(1 + x^{-2/3})}{(x + 3x^{1/3})^2} = 4 \frac{2x^{1/3} + 1 + x^{-2/3}}{x^2 + 6x^{4/3} + 9x^{2/3}}.
\]
We set \( x = y^3 \) and rearrange to get the equivalent condition
\[
y^5 - 2y^3 - 4y^2 + 9y - 4 = (y - 1)^3(y^2 + 3y + 4) \geq 0
\]
which obviously holds. Next let \( p = 1/2 \) in (10). We now need to show that
\[
6(x - 1) \leq (x + 4x^{1/2} + 1) \log x
\]
holds for \( x \geq 1 \). This follows by the same procedure as for \( p = 1/3 \). We still have to show that the right hand side of (10) is concave. However, after we differentiate twice with respect to \( p \) all that remains is
\[
9(x^{p-1} - x^{1-3p}) \log^3 x.
\]
Clearly this is negative for \( x \geq 1 \) and \( p \leq 1/2 \). 

As we noted in remark 3.3, the Stolarsky mean was introduced in [13] as a generalization of the logarithmic mean. The previous lemma may be reformulated to a result of independent interest. This result is related to Pittenger’s inequality, which gives the exact range of values of \( p \) for which the inequality \( A_p^q \geq S_q \) holds (see [6, p. 204]). Note that the bounds in Pittenger’s inequality equal our bounds only for \( q \in [0, 1/2] \cup \{1\} \). For \( q \in (1/2, 1) \), there are \( p \) such that the ratio \( A_p^q/S_q \) is initially increasing but eventually decreases, however its values are never below 1.

**Corollary 4.1.** Let \( 0 \leq q < 1 \). For fixed \( y > 0 \) the ratio \( A_p(x, y)/St_q(x, y) \) is increasing in \( x \geq y \) if and only if \( p \geq \max\{q, (1 + q)/3\} \). In particular, \( A_p(x, y) \geq St_q(x, y) \) for all \( x, y \in \mathbb{R}^+ \) for the same \( p \) and \( q \).

**Proof.** The claim follows directly from Lemma 4.2 and the relationship between \( S \) and \( St \) given in Remark 3.3.

**5. APPLICATIONS**

In this section we combine the results from the previous two sections to derive our main results as to when \( \rho_M \) is a metric.

**Proof (of Theorem 1.1).** Assume that the triangle inequality holds for some pair \((p, q)\) with \( p > 0 \). Then
\[
2 = \rho_{p,q}(-1, 1) \leq \rho_{p,q}(-1, 0) + \rho_{p,q}(0, 1) = 2^{1+q/p},
\]
hence \( q \geq 0 \).
Suppose next that $p < 0$ and $q > 0$. Consider the triangle inequality $\rho_{p,q}(\epsilon, 1) \leq \rho_{p,q}(\epsilon, 1/2) + \rho_{p,q}(1/2, 1)$ as $\epsilon \to 0$. Then the left hand side tends to $\infty$ like $2^{-q/\rho}(1 - \epsilon)\epsilon^{-q}$ and the right hand side like $2^{-q/\rho}(1/2 - \epsilon)\epsilon^{-q}$, a contradiction, for sufficiently small $\epsilon$.

Suppose then that $p, q < 0$. Then $\rho_{p,q}(x, 0) = 0$ for every $x \in X$, contrary to the assumption that $\rho_{p,q}$ is a metric. For $p = 0$ we arrive at contradictions of the triangle inequality by letting $z$ tend to 0 or $\infty$ according as $q$ is greater or less than 0.

Hence only the case $p, q > 0$ remains to be considered. When $q > 1$, the triangle inequality $\rho_{p,q}(x, y) \leq \rho_{p,q}(x, z) + \rho_{p,q}(z, y)$ cannot hold, as we see by letting $z \to \infty$.

The non-trivial cases follow from Lemmas 3.1 and 4.2: if $p \geq \max\{1 - q, 2/3 - q/3\} \rho_{p,q}$ is a metric by the lemmas. If $p < \max\{1 - q, 2/3 - q/3\}$, the ratio in the definition of $\geq$ is decreasing in a neighborhood of 1 or $\infty$ (this is seen in the proof of Lemma 4.2). In the first case $A_p^q(x, 1) < S_q(x, 1)$ in $(1, a)$ for some $a > 1$, contradicting the first condition in Lemma 3.1. In the second case $A_p^q(x, 1)/S_q(x, 1) > A_p^q(x^2, 1)/S_q(x^2, 1)$ holds for sufficiently large $x$ and $\rho_{p,q}$ is not a metric by the second condition in Lemma 3.1.

We will now consider an application of Corollary 3.2.

**Lemma 5.1.** Let $\lambda_M: X \times X \to \mathbb{R}^+$ be defined by the formula
\[
\lambda_M(x, y) := \log\{1 + \rho_M(x, y)\}.
\]
Then $\lambda_{A_p/c}$ is a metric in $X$ if $c \geq 1$ for $p \in [0, \infty]$ and $c \geq 2^{-1/p}$ for $p \in [-\infty, 0)$. The latter bound for the constant $c$ is sharp.

**Proof.** By Corollary 3.2, it suffices to prove the claims in $\mathbb{R}$ with $y < z < x$. We start by showing that $\lambda_{A_p/c}$ is a metric for $c \geq \max\{1, 2^{-1/p}\}$. Since the case $y = 0$ is trivial we may assume that $y > 0$. Denote $f(x) := t_{A_p}(x)$.

The triangle inequality for $\lambda_M$,
\[
\log\{1 + \rho_M(x, y)\} \leq \log\{1 + \rho_M(x, z)\} + \log\{1 + \rho_M(z, y)\},
\]
is equivalent to
\[
\frac{st - 1}{f(st)} \leq \frac{s - 1}{f(s)} + \frac{t - 1}{f(t)} + c \frac{s - 1}{f(s)} \frac{t - 1}{f(t)}
\]
(11)
where $s = x/z$ and $t = z/y$. Since $st - 1 = (s-1)(t-1) + (s-1) + (t-1)$ and since $f$ is increasing and greater than 1, the triangle inequality surely holds if $f(st) \geq f(s)f(t)/c$. However, this follows directly from Chebyshev’s inequality (see [6, p. 50]) for $p > 0$ and is trivial for $p = 0$. For $p < 0$ it follows from the inequality $(1 + s^p)(1 + t^p) \geq 1 + (st)^p$.
We will now show that we cannot choose \( c < 2^{-1/p} \) for \( p < 0 \). Let \( s = t \) in (11): \( (s+1)/f(s^2) \leq 2/f(s) + c(s-1)/(f(s)^2) \). As \( s \to \infty \), \( f(s) \to 2^{1/p} \), hence at the limit \( 2^{1/p}(s+1) \leq 2^{1+1/p} + c2^{2/p}(s-1) \) which implies that \( c \geq 2^{-1/p} \).

We now consider the second special case, \( M(x, y) = f(x)f(y) \).

**Lemma 5.2.** Let \( M(x, y) = f(x)f(y) \) and assume \( f(x) > 0 \) for \( x \geq 0 \). Then \( \rho_M \) is a metric in \( \mathbb{R} \) if and only if \( f \) is MI and convex in \( \mathbb{R}^+ \).

**Proof.** Assume that \( \rho_M \) is a metric in \( \mathbb{R} \). Let \( y = -x \) in the triangle inequality for \( -x < z < x \):

\[
\frac{2x}{f(x)^2} \leq \frac{x-z}{f(x)f(z)} + \frac{x+z}{f(x)f(z)} = \frac{2x}{f(x)f(z)}
\]

Hence \( f(x) \geq f(z) \), i.e. \( f \) is increasing. If \( z > x \), we get instead \( zf(x) \leq xf(z) \), i.e. \( f(x)/x \) is decreasing, so that \( f \) is MI. Let now \( 0 \leq y < z < x \). Then the triangle inequality multiplied by \( f(y)f(z)f(x) \) becomes

\[
(x-y)f(z) \leq (x-z)f(y) + (z-y)f(x).
\] (12)

But this means that \( f \) is convex, [6, p. 61]. (Alternatively, setting \( z =: ay + (1-a)x \) gives the more standard form of the convexity condition, \( f(ay + (1-a)x) \leq af(y) + (1-a)f(x) \).)

Assume then conversely that \( f \) is MI and convex in \( \mathbb{R}^+ \). Then convexity gives (12) for \( 0 \leq y < z < x \), and dividing this inequality by \( f(y)f(z)f(x) \), we get the triangle inequality for the same \( y, z, x \). However, we know from Remark 3.1 that this is a sufficient condition for \( \rho_M \) to be a metric, provided \( M \) is MI.

**Proof (of Theorem 1.2).** If \( \rho_M \) is a metric in \( \mathbb{R}^n \) it is trivially a metric in \( \mathbb{R} \), since \( \mathbb{R}^n \) includes a subspace isometrically isomorphic to \( \mathbb{R} \). Hence the claims regarding \( f \) follow from Lemma 5.2. If \( f: \mathbb{R}^+ \to (0, \infty) \) is MI and convex then \( \rho_M \) is a metric in \( \mathbb{R} \) by Lemma 5.2 and hence in \( \mathbb{R}^n \) by Theorem 3.1.

We now give an example of a relative-metric family where \( M \) is not a mean. Note that this family includes the chordal metric, \( q \), as a special case \( (p = 2) \).

**Example 5.1.** The distance

\[
\frac{|x-y|}{\sqrt{1+|x|^p} \sqrt{1+|y|^p}}
\]
6. FURTHER DEVELOPMENTS

In this section, we show how the approach of this paper can be extended to construct metrics that depend on the domain in which they are defined. The method is based on interpreting $\rho_M$ as $\rho_{M,\mathbb{R}^n\setminus\{0\}}$, where $\rho_{M,G}$ is a distance function (defined in the next lemma) that depends both on the function $M$ and the domain $G$. The proof of the next lemma is similar to that of [12, Theorem 3.3]. Note that the topological operations (closure, boundary etc.) are taken in the compact space $\mathbb{R}^n$.

\begin{lemma}
Let $G \subset \mathbb{R}^n$ with $G \neq \mathbb{R}^n$. If $M$ is continuous in $(0,\infty) \times (0,\infty)$ and $\rho_M$ is a metric then
\[
\rho_{M,G}(x,y) := \sup_{a \in \partial G} \frac{|x-y|}{M(|x-a|,|y-a|)}
\]
is a metric in $G$.
\end{lemma}

\begin{proof}
Clearly only the triangle inequality needs to be considered. Fix two points $x$ and $y$ in $G$. Since $M$ is continuous and $\partial G$ is a closed set in the compact space $\mathbb{R}^n$ there exists a point $a \in \partial G$ such that $\rho_{M,G}(x,y) = \rho_M(x-a,y-a)$. Since
\[
\rho_M(x-a,y-a) \leq \rho_M(x-a,z-a) + \rho_M(z-a,y-a) \leq \rho_{M,G}(x,z) + \rho_{M,G}(z,y)
\]
it follows that $\rho_{M,G}$ is a metric in $G$.
\end{proof}

\begin{remark}
Let $M(x,y) := \min\{x,y\}$. Then
\[
\rho_{M,G}(x,y) = \sup_{a \in \partial G} \frac{|x-y|}{\min\{|x-a|,|y-a|\}} = \frac{|x-y|}{\min\{d(x),d(y)\}},
\]
where $d(x) = d(x,\partial G)$. We then have
\[
\log(1 + \rho_{M,G}(x,y)) = j_G(x,y) := \log \left(1 + \frac{|x-y|}{\min\{d(x),d(y)\}}\right),
\]
which provides our first connection to a well-known metric ($j_G$ occurs in e.g. [3], [12] and [15]).
\end{remark}
The previous lemma provides only a sufficient condition for $\rho_{M,G}$ being a metric. It is more difficult to derive necessary conditions, but with some restrictions on $G$, such as convexity, this might not be impossible.

If $M$ is homogeneous, we have a particularly interesting special case, as we may set

$$\rho_{M,G}'(x,y) = \sup_{a,b \in \partial G} \frac{|y, a, x, b|}{M(|x, b, a, y|)} = \sup_{a,b \in \partial G} \frac{1}{M(|x, y, a, b|, |x, y, b, a|)}$$

where

$$|a, b, c, d| := \frac{q(a,c)q(b,d)}{q(a,b)q(c,d)}$$

(13)
denotes the cross-ratio of the points $a, b, c, d \in \mathbb{R}^n$, $a \neq b$, $c \neq d$ and $q$ denotes the chordal metric (defined in (2)). With this notation we have

**Lemma 6.2.** Let $G \subset \mathbb{R}^n$ with $\text{card} \partial G \geq 2$. If $M$ is increasing and homogeneous and $\rho_M$ is a metric in $\mathbb{R}^n$ then $\rho_{M,G}'$ is a metric in $G$.

**Proof.** Fix points $x$ and $y$ in $G$. There are $a$ and $b$ in the compact set $\partial G$ (possibly $a = \infty$ or $b = \infty$) for which the supremum in $\rho_M'(x,y)$ is attained. By the Möbius invariance of the cross ratio, we may assume that $a = 0$ and $b = \infty$. Then $\rho_{M,G}'(x,y) = \rho_M(x',y')$, where $x'$ and $y'$ are the points corresponding to $x$ and $y$, and we may argue as in the proof of Lemma 6.1.

**Corollary 6.1.** Let $G \subset \mathbb{R}^n$ with $\text{card} \partial G \geq 2$ and let $M(x,y) = \max\{1, 2^{1/p}\} A_p(x,y)$. Then

$$\delta^p_G(x,y) := \log\{1 + \rho_{M,G}'(x,y)\},$$

is a metric in $G$.

**Proof.** Follows directly from Lemmas 5.1 and 6.2.

With this notation we have $\delta_G(x,y) = \delta_G^\infty$, where $\delta_G$ is Seittenranta’s cross ratio metric ([12]). Also note that

$$\delta^p_G = \sup_{a,b \in \partial G} \log\{1 + (|x, a, y, b|^p + |x, b, y, a|^p)^{1/p}\}$$

actually takes on a quite simple form.
Instead of taking the supremum over the boundary we could integrate over it:

\[ \tilde{\rho}_{M,G}^p(x, y) := \left( \int_{\partial G} \rho_M(x - a, y - a)^p \, d\mu \right)^{1/p} \]

(defined for \( \mu \)-measurable \( \partial G \)). This metric takes the boundary into account in a more global manner, but is difficult to evaluate for most \( G \)'s.

**Lemma 6.3.** Let \( \rho_M, G \) and \( \mu \) be such that \( \tilde{\rho}_{M,G}^p(x, y) \) exists for all \( x, y \in G \). If \( \rho_M \) is a metric then \( \tilde{\rho}_{M,G}^p \) is a metric in \( G \) for \( p \geq 1 \).

**Proof.** From Minkowski’s inequality

\[
\left( \int_{\partial G} (f + g)^p \, d\mu \right)^{1/p} \leq \left( \int_{\partial G} f^p \, d\mu \right)^{1/p} + \left( \int_{\partial G} g^p \, d\mu \right)^{1/p},
\]

where \( f, g \geq 0 \) and \( p \geq 1 \), and the basic triangle inequality (take \( f = \rho_M(x - a, z - a) \) and \( g = \rho_M(z - a, y - a) \) above) \( \rho_M(x, y) \leq \rho_M(x, z) + \rho_M(z, y) \) it follows that \( \tilde{\rho}_{M,G}^p \) also satisfies the triangle inequality.

The integral form is quite difficult to evaluate in general, however, we can calculate the following explicit formulae. Note that \( H^2 \) denotes the upper half-plane.

**Lemma 6.4.** For some constants \( c_t \),

\[
\tilde{\rho}_{A_t, H^2}^{1/(1-2t)}(x, y) = c_t \frac{|x - y|}{\sqrt{|x - y|^2 + 4h^2}}
\]

for \( 0 < t < 1/2 \), where \( h \) is the distance from the mid-point of the segment \([x, y]\) to the boundary of \( H^2 \), \( h := d((x + y)/2, \partial H^2) \). Hence

\[
\frac{|x - y|}{\sqrt{|x - y|^2 + 4h^2}}
\]

is a metric in \( H^2 \) for \( 0 < t < 1/2 \).

**Proof.** The formula is derived directly by integration as follows

\[ \tilde{\rho}_{A_t, H^2}^s(x, y) = c \left( \int_{\partial H^2} \frac{dm_1(\xi)}{|x - \xi|^2 + |y - \xi|^2} \right)^{1/s} |x - y| \]

\[ = c \left( \int_{-\infty}^{\infty} dw \frac{d}{a^2 + b^2 + h^2 + w^2} \right)^{1/s} |x - y| \]
where \(2a := x_1 - y_1\) and \(2b := x_2 - y_2\) and \(h\) is as above (\(x_i\) refers to the \(i^{th}\) coordinate of \(x\), similarly for \(y\)). Let us use the variable substitution 
\[ w = \sqrt{a^2 + b^2 + h^2 z}. \]
Then we have
\[
\tilde{\rho}^s_{A_2, H^2}(x, y) = c \left( \int_{-\infty}^{\infty} \sqrt{a^2 + b^2 + h^2 dz} \right)^{1/s} |x - y| = c(|x - y|^2 + 4h^2)^{(1/s-1)/2} |x - y| c_s
\]
where
\[ c_s := \left( \int_{-\infty}^{\infty} \frac{dz}{(1 + z^2)^{s/2}} \right)^{1/s}. \]
Note that \(c_s < \infty\) for \(s > 1\).
The last claim follows directly from Lemma 6.3, since \(\rho_{A_2}\) is a metric, by Theorem 1.1.

**Remark 6.** 2. We saw that
\[ \iota_s(x, y) := \frac{|x - y|}{(|x - y|^2 + 4h^2)^{(1-1/s)/2}} \]
is a metric for \(s > 1\). We then conclude that \(\lim_{s \to \infty} \iota_s\) exists and hence that
\[ \iota_\infty(x, y) := \frac{2|x - y|}{\sqrt{|x - y|^2 + 4h^2}} \]
is a metric also. Note that this metric is a lower bound of the hyperbolic metric in the half-plane, as is seen by the path-length metric method in [8, Section 4].

We may define yet another distance by taking the supremum over two boundary points:
\[ \rho''_{M, G}(x, y) := \sup_{a, b \in \partial G} \frac{|x - y|}{M(|x - a|, |y - b|)}. \]

If we assume that \(M\) is increasing and continuous, this amounts to taking
\[ \rho''_{M, G}(x, y) = \frac{|x - y|}{M(d(x), d(y))}, \quad (14) \]
where \(d(x) := d(x, \partial G).\)
One could ask whether we could construct a general theory for $\rho_{M,G}''$-type metrics. This would be a very interesting theory, since it would involve metrics taking the geometry of the domain into account which would not include a complicated supremum. However, this cannot, in general, be done by our techniques: the following lemma has the important consequence that the proof technique of Lemma 6.1 cannot be extended to metrics of the type $\rho_{M,G}''$. In the following two lemmas we will use the convention that $se_1$ is denoted by $s$ etc.

**Lemma 6.5.** Let $G := \mathbb{R}^n \setminus \{-a, a\}$ ($a > 0$), $n \geq 2$ and assume that $M$ is increasing and continuous. Then $\rho_{M,G}''$ is a metric if and only if $M \equiv c > 0$.

**Proof.** We assume that $\rho_{M,G}''$ is a metric. Consider first the points $-a - r$ and $a + r$ and let $y$ be on the line joining. We may choose $y$ so that $d(y)$ varies between 0 and $r$. Then, by the triangle inequality,

$$
\frac{2(r + a)}{M(r, r)} = \rho_{M,G}''(-r - a, r + a) 
\leq \rho_{M,G}''(-r - a, y) + \rho_{M,G}''(y, r + a) = \frac{2(r + a)}{M(r, d(y))}.
$$

Consider next the points $-a + re_2$ and $a + re_2$ and let $y$ be on the line joining them. We have

$$
\frac{2a}{M(r, r)} \leq \frac{2a}{M(r, d(y))}
$$

but now $d(y)$ varies between $r$ and $\sqrt{r^2 + a^2}$. Hence we have $M(x, y) \leq M(x, x)$ for $y \in [0, \sqrt{x^2 + a^2}]$.

Let us now consider the points $x_1 := -a - s + he_2$, $y := a - s + he_2$ and $x_2 := a + t + he_2$, for $t \geq 0$ and $s \leq a$. We have

$$
\frac{2a + s + t}{M(r, d(x_2))} = \rho_{M,G}''(x_1, x_2) \leq \rho_{M,G}''(x_1, y) + \rho_{M,G}''(y, x_2) = \frac{2a}{M(r, r)} + \frac{s + t}{M(r, d(x_2))},
$$

where $r = \sqrt{s^2 + h^2}$. From this it follows that $M(r, r) \leq M(r, y)$ where $y = \sqrt{r^2 + h^2} = \sqrt{r^2 - s^2 + t^2}$. Combining the upper and lower bounds, we conclude that $M(x, x) = M(x, y)$ for $y \in [\sqrt{b}, \sqrt{x^2 + a^2}]$, where $b := \max\{0, x^2 - a^2\}$. From this it follows easily that $M \equiv c$. 

The next idea might be to build a theory of \( \rho_{M,G}' \)-type metrics for sufficiently regular, e.g. convex domains only. The following lemma shows that this approach does not show much promise, either. (Note that \( B^n \) denotes the unit ball.)

**Lemma 6.6.** Let \( P: (0,1] \times (0,1] \to (0,\infty) \) be symmetric, increasing and continuous. Then \( \rho_{P,B^n}' \) is a metric if and only if \( P \equiv c > 0 \).

**Proof.** According to (14)

\[
\rho_{P,B^n}'(x, y) = \frac{|x - y|}{P(d(x), d(y))} = \frac{|x - y|}{P(1 - |x|, 1 - |y|)}.
\]

Consider the triangle inequality of the points \(-r, 0\) and \(r, 0\), \(0 < r < 1\):

\[
\frac{2r}{P(1 - r, 1 - r)} \leq \frac{2r}{P(1, 1 - r)}.
\]

This implies that \( P(1, s) \leq P(s, s) \) for \( 0 < s \leq 1 \), and, since \( P \) is increasing, \( P(1, s) = P(t, s) \) for \( 0 < s \leq t \leq 1 \).

It follows that there exists an increasing function \( g: (0,1] \to (0,\infty) \) such that \( P(x, y) = g(\min\{x, y\}) \). Take points \( 0 < y < z < x \leq 1 \) on the \( e_1 \)-axis. Then the triangle inequality

\[
\frac{x - y}{g(y)} \leq \frac{x - z}{g(z)} + \frac{z - y}{g(y)}
\]

implies that \( g(z) \leq g(y) \) and since \( g \) is increasing by assumption it follows that \( g \), and hence \( P \), is constant.

Since the unit ball is in many respects as regular a domain as possible, we see that the prospects of generalizing the theory by restricting the domain are not good. A better approach seems to be to consider \( \log\{1 + \rho_{M,G}'(x, y)\} \), since we know from Remark 3.2 that this can be a metric even though \( \rho_{M,G}'(x, y) \) is not. The metric \( j_G \) is an example of such a metric. This line of research seems to be the most promising further extension.

**ACKNOWLEDGMENT**

I would like to thank Matti Vuorinen for suggesting the topic of this paper to me. I would also like to thank Glen D. Anderson, Horst Alzer and Pentti Järvi and the referee for their comments on various versions of this manuscript.
