Law-invariant risk measures:
extension properties and qualitative robustness*

Abstract

We characterize when a convex risk measure associated to a law-invariant acceptance set in $L^\infty$ can be extended to $L^p$, $1 \leq p < \infty$, preserving finiteness and continuity. This problem is strongly connected to the statistical robustness of the corresponding risk measures. Special attention is paid to concrete examples including risk measures based on expected utility, max-correlation risk measures, and distortion risk measures.

Keywords: extension of risk measures, acceptance sets, law invariance, statistical robustness, expected utility, max-correlation risk measures, distortion risk measures

MSC: 91B30, 91G80

1 Introduction

The objective of this paper is to complement the paper [10] by Filipović and Svindland. The main result in that paper is Theorem 2.2 stating that every convex, law-invariant, lower semicontinuous map $f : L^\infty \rightarrow \mathbb{R} \cup \{\infty\}$ can be uniquely extended to a map on $L^1$ satisfying the same properties. In this sense, $L^1$ can be viewed as the canonical space for this type of maps. The results in [10] are presented
in the context of a standard probability space but can be extended to a nonatomic setting as shown in Svindland [18].

The authors in [10] are mostly concerned with the application of their results in the context of cash-additive risk measures. It is well-known that any cash-additive risk measure on \( L^\infty \) is automatically finite-valued and (Lipschitz) continuous. It is also well-known that cash-additive risk measures on \( L^p \), \( 1 \leq p < \infty \), need not be either finite-valued or continuous. Consequently, the following two questions arise in a natural way: *When does a cash-additive risk measure on \( L^\infty \) admit a finite-valued, continuous extension to \( L^p \) for a given \( 1 \leq p < \infty \), and, which is the “largest” space \( L^p \) for which such an extension exists?*

We provide a full answer to the previous questions, characterizing those convex, law-invariant, cash-additive risk measures defined on \( L^\infty \) that can be extended to \( L^p \) spaces preserving finiteness and continuity. In fact, our main result provides a characterization in the more general setting of risk measures studied by Farkas, Koch-Medina, and Munari in [8], where cash additivity is not required. More precisely, we show that the existence of finite, continuous extensions depends on the properties of the underlying acceptance sets. Special attention is paid to several concrete examples, including risk measures based on expected utility, max-correlation risk measures, and distortion risk measures. These examples show that, if finiteness and continuity are to be preserved, the “canonical” model space for convex, law-invariant risk measures is not always \( L^1 \) but can be any space \( L^p \), \( 1 \leq p \leq \infty \). In particular, there are (even cash-additive) risk measures that cannot be extended beyond \( L^\infty \) maintaining finiteness and continuity.

The previous questions turn out to be intimately related to the statistical robustness for risk measures as discussed by Krätschmer, Schied, and Zähle in [15], highlighting the practical relevance of our results and our examples. Indeed, when risk measures are implemented to define capital adequacy requirements for financial institutions, or margin requirements for the participants of a central exchange, their statistical robustness is crucial to guarantee that the corresponding capital requirements are stable with respect to small changes in the distributions of the underlying positions. In this respect, our examples can be seen to be complementary to [15].

2 Preliminaries

Let \( \mathcal{X} \) be an ordered topological vector space over \( \mathbb{R} \) with positive cone \( \mathcal{X}_+ \) and topological dual \( \mathcal{X}' \). The space \( \mathcal{X} \) represents the set of all possible capital positions – assets net of liabilities – of financial institutions at a fixed future date \( t = T \).

We assume \( \mathcal{A} \subset \mathcal{X} \) is an acceptance set, i.e., a nonempty, proper subset of \( \mathcal{X} \) satisfying \( \mathcal{A} + \mathcal{X}_+ \subset \mathcal{A} \). We interpret the elements of \( \mathcal{A} \) as those capital positions which are deemed acceptable by an external or internal “regulator”. Moreover, let \( S = (S_0, S_T) \) represent a traded asset with price \( S_0 > 0 \) at time \( t = 0 \) and nonzero, terminal payoff \( S_T \in \mathcal{X}_+ \) at time \( t = T \). The risk measure associated to \( \mathcal{A} \) and \( S \) is the map \( \rho_{\mathcal{A},S} : \mathcal{X} \to \mathbb{R} \) defined by

\[
\rho_{\mathcal{A},S}(X) := \inf \left\{ m \in \mathbb{R} ; \ X + \frac{m}{S_0} S_T \in \mathcal{A} \right\}. \tag{1}
\]
For a position $X \in \mathcal{X}$, the quantity $\rho_{\mathcal{A},S}(X)$ represents the “minimum” amount of capital that needs to be raised and invested in the asset $S$ to guarantee acceptability. Clearly, a negative $\rho_{\mathcal{A},S}(X)$ implies that capital is returned to shareholders. The motivation for studying this type of risk measures is discussed in detail in [8], where general results on finiteness and continuity are also provided.

We are particularly interested in the case where $\mathcal{X}$ is the Banach space $L^p$, $1 \leq p \leq \infty$, defined over a probability space $(\Omega, \mathcal{F}, \mathbb{P})$, which we assume to be nonatomic. The corresponding norm is denoted by $\|\cdot\|_p$. The space $L^p$ becomes a Banach lattice when additionally equipped with the canonical order structure, i.e., $X \geq Y$ whenever this inequality holds almost surely. The conjugate of $p$ will be denoted by $p'$, i.e., we set $p' := \frac{p}{1-p}$.

When $\mathcal{X} = L^p$ for some $1 \leq p \leq \infty$, we can consider risk measures $\rho_{\mathcal{A},S}$ with respect to the cash asset $S = (1,1)$. These risk measures are called cash additive. We refer to [11] for a comprehensive treatment when $p = \infty$. For cash-additive risk measures, we simply write for $X \in L^p$

$$\rho_{\mathcal{A}}(X) := \rho_{\mathcal{A},S}(X) = \inf\{m \in \mathbb{R}; \ X + m \in \mathcal{A}\}. \quad (2)$$

Note that our general setting also allows for a traded asset $S = (S_0,S_T)$ with an arbitrary, positive, random payoff. Hence, we can also cover situations where no risk-free security exists, as discussed in [8].

3 The general extension theorem

In this section we provide the key extension result for risk measures of the form $\rho_{\mathcal{A},S}$. Although our main interest lies in convex risk measures on $L^p$ spaces, to highlight the underlying structure of our result we first study extension theorems in the setting of abstract ordered topological vector spaces. Throughout this section $\mathcal{L}$ and $\mathcal{I}$ will denote two ordered topological vector spaces over $\mathbb{R}$ with respective positive cones $\mathcal{L}^+$ and $\mathcal{I}^+$. We assume that $\mathcal{I}$ is a dense subspace of $\mathcal{L}$. Hence, in addition to its own topology, the space $\mathcal{I}$ can be equipped with the relative topology induced by $\mathcal{L}$, which we call the $\mathcal{L}$-topology. Moreover, since every functional on $\mathcal{L}$ can be restricted to a functional on $\mathcal{I}$, we may also consider the weak topology $\sigma(\mathcal{I},\mathcal{L}')$ on $\mathcal{I}$ where, by abuse of notation, we do not distinguish between functionals on $\mathcal{L}$ and their restrictions to $\mathcal{I}$. In the next section we will take $\mathcal{L} = L^p$, for some $1 \leq p < \infty$, and $\mathcal{I} = L^\infty$.

The following theorem is our main result. For a subset $\mathcal{A} \subset \mathcal{L}$, we denote by $\text{cl}_{\mathcal{L}}(\mathcal{A})$ the closure of $\mathcal{A}$ with respect to the topology on $\mathcal{L}$.

**Theorem 3.1.** Let $\mathcal{A} \subset \mathcal{I}$ be a convex, $\sigma(\mathcal{I},\mathcal{L}')$-closed acceptance set and $S = (S_0,S_T)$ a traded asset with $S_T \in \mathcal{I}^+$. Assume $\rho_{\mathcal{A},S}$ is finite-valued and continuous on $\mathcal{I}$. The following statements are equivalent:

(a) $\rho_{\mathcal{A},S}$ can be extended to a finite-valued, continuous risk measure on $\mathcal{L}$;

(b) $\rho_{\mathcal{A},S}$ is continuous at 0 with respect to the $\mathcal{L}$-topology;

(c) $\mathcal{A}$ has nonempty interior with respect to the $\mathcal{L}$-topology;
(d) $\text{cl}_\mathcal{X}(\mathcal{A})$ has nonempty interior in $\mathcal{L}$.

In this case, the extension is unique and is given by $\rho_{\text{cl}_\mathcal{X}(\mathcal{A}),S}$.

Before proving Theorem 3.1, it is useful to collect some auxiliary results.

**Dual representations and continuity**

Let $\mathcal{X}$ be an ordered topological vector space over $\mathbb{R}$ with positive cone $\mathcal{X}_+$ and topological dual $\mathcal{X}'$. By $\mathcal{X}_+^\prime$ we denote the set of all functionals $\psi \in \mathcal{X}'$ satisfying $\psi(X) \geq 0$ for every $X \in \mathcal{X}_+$. We start by stating a dual representation result for convex risk measures of the form $\rho_{\mathcal{A},S}$ in a version that is convenient for our purposes.

The (lower) support function of a subset $\mathcal{A} \subset \mathcal{X}$ is the map $\sigma_\mathcal{A} : \mathcal{X}' \to \mathbb{R} \cup \{-\infty\}$ defined by

$$\sigma_\mathcal{A}(\psi) := \inf_{A \in \mathcal{A}} \psi(A). \quad (3)$$

The set

$$B(\mathcal{A}) := \{\psi \in \mathcal{X}' ; \; \sigma_\mathcal{A}(\psi) > -\infty\} \quad (4)$$

is called the barrier cone of $\mathcal{A}$. Clearly, the support function of a set $\mathcal{A} \subset \mathcal{X}$ always coincides with the support function of its closure.

By combining Corollary 4.14 and Theorem 4.16 in [9] we obtain the following result.

**Lemma 3.2.** Let $\mathcal{A} \subset \mathcal{X}$ be a closed, convex acceptance set and $S = (S_0, S_T)$ a traded asset, and set

$$\mathcal{X}_+^\prime,S := \{\psi \in \mathcal{X}_+^\prime ; \; \psi(S_T) = S_0\}. \quad (5)$$

Then the following statements are equivalent:

(a) $\rho_{\mathcal{A},S}$ attains some finite value;

(b) $\rho_{\mathcal{A},S}$ does not attain the value $-\infty$;

(c) $\mathcal{X}_+^\prime,S \cap B(\mathcal{A})$ is nonempty.

In this case, for every $X \in \mathcal{X}$ we have

$$\rho_{\mathcal{A},S}(X) = \sup_{\psi \in \mathcal{X}_+^\prime,S} \{\sigma_\mathcal{A}(\psi) - \psi(X)\}. \quad (6)$$

**Remark 3.3.** Later we will apply this result to the situation where $\mathcal{X}$ is either $\mathcal{L}$, equipped with its own topology, or $\mathcal{I}$, equipped with the $\sigma(\mathcal{I}, \mathcal{L})$ topology. Since both of these spaces have the same dual $\mathcal{L}'$ we see that for a subset $\mathcal{A} \subset \mathcal{I}$

$$\sigma_\mathcal{A}(\psi) = \sigma_{\text{cl}_\mathcal{X}(\mathcal{A})}(\psi) \quad \text{for all } \psi \in \mathcal{L}', \quad (7)$$

where $\sigma_\mathcal{A}$ is applied to the restriction of $\psi \in \mathcal{L}'$ to $\mathcal{I}$. In particular, the intersection $\mathcal{L}_+^\prime,S \cap B(\mathcal{A})$ is nonempty if and only if $\mathcal{L}_+^\prime,S \cap B(\text{cl}_\mathcal{X}(\mathcal{I}))$ is also nonempty.
We now recall a necessary and a sufficient condition for a risk measure of the form \( \rho_{\mathcal{A},S} \) to be continuous on \( \mathcal{X} \). For a proof, we refer to Lemma 2.5 and Theorem 3.10 in [8], respectively.

**Lemma 3.4.** Let \( \mathcal{A} \subset \mathcal{X} \) be an acceptance set and \( S = (S_0, S_T) \) a traded asset.

(i) If \( \rho_{\mathcal{A},S} \) is continuous at some point \( X \in \mathcal{X} \) with \( \rho_{\mathcal{A},S}(X) < \infty \), then \( \mathcal{A} \) has nonempty interior.

(ii) Assume \( \mathcal{A} \) is convex and has nonempty interior. Then \( \rho_{\mathcal{A},S} \) is continuous whenever it is finite-valued.

**Proof of Theorem 3.1**

Assume (a) holds, i.e., \( \rho_{\mathcal{A},S} \) admits an extension to a finite-valued, continuous map on \( \mathcal{L} \). Then, clearly, \( \rho_{\mathcal{A},S} \) must also be continuous with respect to the \( \mathcal{L} \)-topology. It follows that (b) holds.

Let (b) hold so that \( \rho_{\mathcal{A},S} \) is continuous at 0 with respect to the \( \mathcal{L} \)-topology. Since \( \rho_{\mathcal{A},S} \) is finite at 0, Lemma 3.4 implies that \( \mathcal{A} \) must have nonempty interior with respect to the \( \mathcal{L} \)-topology, hence (c) holds.

Now, assume that (c) holds so that \( \mathcal{A} \) has nonempty interior with respect to the \( \mathcal{L} \)-topology. As a result, we find an open subset \( \mathcal{U} \) of \( \mathcal{L} \) such that \( \mathcal{U} \cap \mathcal{A} \subset \mathcal{A} \). Since \( \mathcal{A} \) is dense in \( \mathcal{L} \) and \( \mathcal{U} \) is open in \( \mathcal{L} \), we have that \( \mathcal{U} \cap \mathcal{A} \) is nonempty and

\[
\text{cl}_\mathcal{L}(\mathcal{U}) = \text{cl}_\mathcal{L}(\mathcal{U} \cap \mathcal{A}).
\]

(8)

It follows that

\[
\mathcal{U} \subset \text{cl}_\mathcal{L}(\mathcal{U}) = \text{cl}_\mathcal{L}(\mathcal{U} \cap \mathcal{A}) \subset \text{cl}_\mathcal{L}(\mathcal{A}),
\]

(9)

proving that \( \text{cl}_\mathcal{L}(\mathcal{A}) \) has nonempty interior in \( \mathcal{L} \) and, hence, that (d) holds.

Finally, assume that (d) holds, i.e., \( \text{cl}_\mathcal{L}(\mathcal{A}) \) has nonempty interior in \( \mathcal{L} \). Since \( \mathcal{A} \) is convex and \( \sigma(\mathcal{J}, \mathcal{L}') \)-closed and \( \rho_{\mathcal{A},S} \) is finite-valued on \( \mathcal{J} \), Lemma 3.2 implies that \( \mathcal{L}'_+ \cap B(\mathcal{A}) \) is nonempty and

\[
\rho_{\mathcal{A},S}(X) = \sup_{\psi \in \mathcal{L}'_+} \{ \sigma_{\mathcal{A}}(\psi) - \psi(X) \}
\]

(10)

for every \( X \in \mathcal{J} \).

In particular, it follows that \( \mathcal{L}'_+ \cap B(\text{cl}_\mathcal{L}(\mathcal{A})) \) is nonempty by Remark 3.3 so that we can apply Lemma 3.2 once again to obtain

\[
\rho_{\text{cl}_\mathcal{L}(\mathcal{A}),S}(X) = \sup_{\psi \in \mathcal{L}'_+} \{ \sigma_{\text{cl}_\mathcal{L}(\mathcal{A})}(\psi) - \psi(X) \} = \sup_{\psi \in \mathcal{L}'_+} \{ \sigma_{\mathcal{A}}(\psi) - \psi(X) \}
\]

(11)

for all \( X \in \mathcal{L} \). This shows that \( \rho_{\text{cl}_\mathcal{L}(\mathcal{A}),S} \) extends \( \rho_{\mathcal{A},S} \) to the whole of \( \mathcal{L} \). We claim that \( \rho_{\text{cl}_\mathcal{L}(\mathcal{A}),S} \) is finite-valued and continuous.

Indeed, note first that, again by Lemma 3.2, the map \( \rho_{\text{cl}_\mathcal{L}(\mathcal{A}),S} \) cannot take the value \( -\infty \). Consider now the convex set

\[
\mathcal{D} := \{ X \in \mathcal{L} \mid \rho_{\text{cl}_\mathcal{L}(\mathcal{A}),S}(X) < \infty \} = \{ X \in \mathcal{L} \mid \rho_{\text{cl}_\mathcal{L}(\mathcal{A}),S}(X) \in \mathbb{R} \}.
\]

(12)
Since \( \text{cl}_\mathcal{L}(\mathcal{A}) \subset \mathcal{D} \), the interior of \( \mathcal{D} \) is nonempty. Now, assume there exists \( X \in \mathcal{L} \setminus \mathcal{D} \). In this case, by a standard separation argument we find a nonzero \( \psi \in \mathcal{L}' \) such that \( \psi(X) \leq \psi(Y) \) for every \( Y \in \mathcal{D} \). Since \( \rho_{\mathcal{A},\mathcal{S}} \) is finite-valued, the set \( \mathcal{D} \) contains the subspace \( \mathcal{J} \). As a consequence, \( \psi \) must annihilate \( \mathcal{S} \) and therefore, by density, the whole of \( \mathcal{L} \). This is not possible since \( \psi \) was nonzero. Hence, \( \mathcal{D} = \mathcal{L} \), showing that \( \rho_{\text{cl}_\mathcal{L}(\mathcal{A}),\mathcal{S}} \) is finite-valued and, by Lemma 3.4, continuous on \( \mathcal{L} \). It follows that (d) implies (a).

We conclude the proof of Theorem 3.1 by observing that any continuous extension of \( \rho_{\mathcal{A},\mathcal{S}} \) must be unique because \( \mathcal{J} \) is dense in \( \mathcal{L} \).

4 Extension of risk measures on \( L^p \) spaces

We now apply Theorem 3.1 to risk measures of the form \( \rho_{\mathcal{A},\mathcal{S}} \) on \( L^p \) spaces when the underlying acceptance set \( \mathcal{A} \) is convex and law-invariant. Recall that a set \( \mathcal{A} \subset L^p \) is called law-invariant if \( X \in \mathcal{A} \) whenever \( X \sim Y \) for some \( Y \in \mathcal{A} \). Here, we write \( X \sim Y \) to indicate that \( X \) and \( Y \) have the same law. Similarly, a map \( f : L^p \to \mathbb{R} \) is said to be law-invariant if \( f(X) = f(Y) \) whenever \( X \sim Y \).

Remark 4.1. Recall that every closed, convex, law-invariant set \( \mathcal{A} \subset L^\infty \) is also closed with respect to the \( \sigma(L^{\infty},L^p) \)-topology for any \( 1 \leq p \leq \infty \). This property was first shown in the context of standard probability spaces by Jouini, Schachermayer and Touzi, see Remark 4.4 in [16], and was later extended to general nonatomic spaces by Svindland, see Proposition 1.2 in [18].

Remark 4.2. Consider a law-invariant acceptance set \( \mathcal{A} \subset L^\infty \) and a traded asset \( \mathcal{S} = (S_0,S_T) \). It is immediate to see that the risk measure \( \rho_{\mathcal{A},\mathcal{S}} \) is also law-invariant whenever the payoff \( S_T \) is deterministic. In particular, the cash-additive risk measure \( \rho_{\mathcal{A}} \) is always law-invariant if \( \mathcal{A} \) is law-invariant. However, this need not be the case if \( S_T \) is genuinely random, as illustrated by the following important example.

1. The Value-at-Risk and Tail Value-at-Risk of \( X \in L^\infty \) at the level 0 < \( \alpha < 1 \) are defined, respectively, by
   \[
   \text{VaR}_\alpha(X) := \inf \{m \in \mathbb{R}; \mathbb{P}(X + m < 0) \leq \alpha \},
   \]
   \[
   \text{TVaR}_\alpha(X) := \frac{1}{\alpha} \int_0^\alpha \text{VaR}_\beta(X)d\beta.
   \]

As is well-known, e.g. [11], both are law-invariant, cash-additive risk measures. Moreover, TVaR\(_\alpha\) is always coherent while VaR\(_\alpha\) is not convex in general. In particular, we can consider the law-invariant acceptance set based on Tail Value-at-Risk at level \( \alpha \)
   \[
   \mathcal{A}^\alpha := \{X \in L^\infty; \text{TVaR}_\alpha(X) \leq 0\}.
   \]

We claim that \( \rho_{\mathcal{A}^\alpha,\mathcal{S}} \) is never law-invariant unless \( S_T \) is deterministic, in which case \( \rho_{\mathcal{A}^\alpha,\mathcal{S}} \) is just a multiple of TVaR\(_\alpha\).

To see this, assume \( S_T \) is not deterministic so that there exist \( \gamma_2 > \gamma_1 > 0 \) for which \( \mathbb{P}(S_T \leq \gamma_1) > 0 \) and \( \mathbb{P}(S_T \geq \gamma_2) > 0 \). Since \((\Omega,\mathcal{F},\mathbb{P})\) is nonatomic, we can find measurable sets \( A \subset \{S_T \leq \gamma_1\} \) and
\[ B \subset \{ S_T \geq \gamma_2 \} \]\text{ satisfying } \mathbb{P}(A) = \mathbb{P}(B) = p \text{ with } 0 < p < 1 - \alpha. \text{ Set now } C = (A \cup B)^c \text{ and note that } \mathbb{P}(C) = 1 - 2p. \text{ For } -\gamma_2 < \lambda < -\gamma_1 \text{ we define }

\[ X := \lambda 1_A - S_T 1_C \quad \text{and} \quad Y := \lambda 1_B - S_T 1_C. \] \tag{16}

Then clearly \( X \sim Y \). We now show that \( \rho_{\mathcal{A},S}(X) > S_0 \geq \rho_{\mathcal{A},S}(Y) \), implying that \( \rho_{\mathcal{A},S} \) is not law-invariant.

Indeed, note first that \( Y + S_T \geq 0 \) so that \( \rho_{\mathcal{A},S}(Y) \leq S_0 \). Now take \( m < 0 \). Then

\[ \mathbb{P}(X + S_T + m < 0) \geq \mathbb{P}(A) + \mathbb{P}(C) = 1 - p > \alpha, \] \tag{17}

implying \( \text{VaR}_\beta(X + S_T) \geq 0 \) for all \( 0 < \beta \leq \alpha \) and, hence, \( \text{TVaR}_\alpha(X + S_T) \geq 0 \). Moreover, if \( 0 \leq m < -\lambda - \gamma_1 \) then \( \mathbb{P}(X + S_T + m < 0) = \mathbb{P}(A) = p \), and therefore \( \text{VaR}_\beta(X + S_T) \geq -\lambda - \gamma_1 > 0 \) whenever \( 0 < \beta < p \). It follows that \( \text{TVaR}_\alpha(X + S_T) > 0 \), showing that \( \rho_{\mathcal{A},S}(X) > S_0 \) as claimed.

2. Sometimes \( \rho_{\mathcal{A},S} \) is law-invariant even if \( S_T \) is not deterministic. \text{ For example, consider the law-invariant acceptance set }

\[ \mathcal{A} := \{ X \in L^\infty; \mathbb{E}[X] \geq \alpha \} \] \tag{18}

where \( \alpha \in \mathbb{R} \). \text{ Since } \rho_{\mathcal{A},S}(X) = \frac{\mathbb{E}[S_T](\alpha - \mathbb{E}[X])}{\mathbb{E}[S_T]} \text{ for any } X \in L^\infty, \text{ the risk measure } \rho_{\mathcal{A},S} \text{ is law-invariant regardless of the choice of the traded asset } S.

The following result provides a general extension result for risk measures associated to convex, law-invariant acceptance sets. If \( \mathcal{A} \subset L^\infty \), we denote by \( \text{cl}_p(\mathcal{A}) \) the closure of \( \mathcal{A} \) in \( L^p \), \( 1 \leq p < \infty \). \text{ Note that } every finite-valued risk measure \( \rho_{\mathcal{A},S} \) on \( L^p \), \( 1 \leq p \leq \infty \), \text{ is automatically continuous when } \mathcal{A} \text{ is convex by Theorem 1 in [1].}

**Theorem 4.3.** \text{ Let } \mathcal{A} \subset L^\infty \text{ be a convex, law-invariant acceptance set and consider a traded asset } S = (S_0, S_T) \text{ with } S_T \in L^\infty. \text{ Assume } \rho_{\mathcal{A},S} \text{ is finite-valued and, hence, continuous on } L^\infty. \text{ For every } 1 \leq p < \infty, \text{ the following statements are equivalent:}

(a) \( \rho_{\mathcal{A},S} \) can be extended to a finite-valued and, hence, continuous risk measure on \( L^p \);
(b) if \( (X_n) \subset L^\infty \) and \( X_n \rightarrow 0 \) in \( L^p \), then \( \rho_{\mathcal{A},S}(X_n) \rightarrow \rho_{\mathcal{A},S}(0) \);
(c) \( \text{cl}_\infty(\mathcal{A}) \) has nonempty interior with respect to the \( L^p \)-topology;
(d) \( \text{cl}_p(\mathcal{A}) \) has nonempty interior in \( L^p \).

In this case, the extension is unique and is given by \( \rho_{\text{cl}_p(\mathcal{A}),S} \).

**Proof.** Since \( \rho_{\mathcal{A},S} \) is assumed to be continuous on \( L^\infty \), we have \( \rho_{\mathcal{A},S} = \rho_{\text{cl}_\infty(\mathcal{A}),S} \) by Lemma 2.5 in [8]. \text{ Note that } \text{cl}_\infty(\mathcal{A}) \text{ is still convex and law-invariant. Indeed, } \rho_{\mathcal{A}} \text{ is law-invariant and } \text{cl}_\infty(\mathcal{A}) \text{ consists of all } X \in L^\infty \text{ such that } \rho_{\mathcal{A}}(X) \leq 0. \text{ As a consequence, the theorem follows from Theorem 3.1 and Remark 4.1.} \quad \square
As a consequence of Theorem 4.3, it is natural to define the index of finiteness of a risk measure $\rho_{A,S}$ as follows:

**Definition 4.4.** Let $A \subset L^\infty$ be a convex, law-invariant acceptance set and consider a traded asset $S = (S_0,S_T)$ with $S_T \in L^\infty$. If $\rho_{A,S}$ is finite-valued on $L^\infty$, the **index of finiteness** of $\rho_{A,S}$ is defined as

$$\text{fin}(\rho_{A,S}) := \inf \{ p \in [1,\infty) ; \text{cl}_p(A) \text{ has nonempty interior in } L^p \}.$$  \(19\)

If the infimum in (19) is attained and we set $p := \text{fin}(\rho_{A,S})$, then $L^p$ is the largest space for which there exists a finite-valued and, hence, continuous extension of $\rho_{A,S}$. Therefore, if we are interested in preserving finiteness and continuity properties of a risk measure, the space $L^p$ is to be considered the canonical model space for $\rho_{A,S}$. From this perspective, the canonical model space for convex, law-invariant (cash-additive) risk measures is not always $L^1$, but will depend on the individual risk measure. As illustrated below, for every $1 \leq p \leq \infty$ we can find convex, law-invariant, cash-additive risk measures having index of finiteness equal to $p$. In particular, there are risk measures of this type which cannot be extended beyond $L^\infty$ in a way that preserves finiteness and continuity.

**Remark 4.5.** Note that the existence of a finite-valued, continuous extension of a risk measure $\rho_{A,S}$ satisfying the assumptions of Theorem 4.3 does not depend on the properties of the payoff $S_T$, but only on the topological properties of the acceptance set $A$. An important consequence is that, if $\rho_{A,S}$ is finite-valued on $L^\infty$, then

$$\text{fin}(\rho_{A,S}) = \text{fin}(\rho_{A,S}).$$  \(20\)

However, the finiteness of $\rho_{A,S}$ on $L^\infty$ does depend on the interplay between the acceptance set and the traded asset, as illustrated by our next examples and extensively documented in [8].

## 5 Qualitative robustness

In this section we recall the notion of qualitative robustness introduced by Krätschmer, Schied, and Zähle in [14] and we discuss the link with our previous results.

Consider a law-invariant acceptance set $A \subset L^\infty$ and its associated cash-additive risk measure $\rho_{A}$ which is, then, also law-invariant. If we denote by $\mathbb{P}_X$ the law of $X$, i.e. $\mathbb{P}_X(A) := \mathbb{P}(X \in A)$ for all Borel sets $A \subset \mathbb{R}$, and set

$$\mathcal{M}^\infty := \{ \mathbb{P}_X ; X \in L^\infty \},$$  \(21\)

we can define a functional $\mathcal{R}_{A} : \mathcal{M}^\infty \to \mathbb{R}$ by

$$\mathcal{R}_{A}(\mathbb{P}_X) := \rho_{A}(X).$$  \(22\)

The capital position $X$ of a financial institution is often estimated through a sequence of historical observations $x_1,\ldots,x_N \in \mathbb{R}$, and the quantity $\mathcal{R}_{A}(m)$, where $m$ denotes the empirical distribution of these observations, is used as a natural proxy for $\rho_{A}(X)$. The importance of the robustness properties of the operator $\mathcal{R}_{A}$ were discussed in detail by Cont, Deguest, and Scandolo in [4]. Based on that paper, a refined notion of qualitative robustness has been recently proposed in [14] and further studied in [15].
Let $\mathcal{M}$ denote the set of (Borel) probability measures over $\mathbb{R}$. To any $\mu \in \mathcal{M}$ which is not a Dirac measure, we can associate a nonatomic probability space $(\Omega^\mu, \mathcal{F}^\mu, \mathbb{P}^\mu)$ supporting a sequence $(X_n)$ of i.i.d. random variables having $\mu$ as their common law, see for instance Section 11.4 in [5]. For $n \in \mathbb{N}$, the empirical distribution of $X_1, \ldots, X_n$ is the map $m_n^\mu : \Omega^\mu \to \mathcal{M}_\infty$ defined by

$$m_n^\mu(\omega) := \frac{1}{n} \sum_{i=1}^{n} \delta_{X_i(\omega)} \quad \text{for } \omega \in \Omega^\mu,$$

where $\delta_{X_i(\omega)}$ denotes the standard Dirac measure associated to the singleton $\{X_i(\omega)\}$. Moreover, we can consider the random variable $R_\mathcal{A}(m_n^\mu)$ given by

$$R_\mathcal{A}(m_n^\mu)(\omega) := R_\mathcal{A}(m_n^\mu(\omega)) \quad \text{for } \omega \in \Omega^\mu.$$

The following notion of qualitative robustness is a generalization of the classical notion introduced by Hampel in [12]. For $1 \leq p < \infty$ define $\psi_p(x) := \frac{1}{p} |x|^p$, $x \in \mathbb{R}$, and recall from [15] that a set $\mathcal{N} \subset \mathcal{M}$ is said to be uniformly $p$-integrating if

$$\lim_{M \to \infty} \sup_{\mu \in \mathcal{N}} \int_{\{|\psi_p(x)| \geq M\}} \psi_p(x) \, d\mu(x) = 0.$$

**Definition 5.1.** The functional $R_\mathcal{A}$ is said to be $p$-robust on $\mathcal{M}_\infty$, $1 \leq p < \infty$, if for any uniformly $p$-integrating set $\mathcal{N} \subset \mathcal{M}_\infty$, $\mu \in \mathcal{N}$ and $\epsilon > 0$ there exist $\delta > 0$ and $n_0 \in \mathbb{N}$ such that

$$d_\mathcal{P}(\mu, \nu) + \left| \int_{\mathbb{R}} \psi_p(x) \, d\mu(x) - \int_{\mathbb{R}} \psi_p(x) \, d\nu(x) \right| \leq \delta$$

implies

$$d_\mathcal{P}\left(\mathbb{P}_R(m_n^\mu), \mathbb{P}_R(m_n^\nu)\right) \leq \epsilon$$

for $\nu \in \mathcal{N}$ and $n \geq n_0$, where $d_\mathcal{P}$ denotes the usual Prohorov metric over $\mathcal{M}$.

Hence, if $R_\mathcal{A}$ is $p$-robust on $\mathcal{M}_\infty$, then a suitable small change in the law of the data entails an arbitrarily small change in the law of the corresponding estimators.

**Remark 5.2.** As discussed in [14] and [15], the choice to add an additional term to the Prohorov metric in (26), as opposed to the classical framework developed by Hampel in [12], has the main advantage of making $R_\mathcal{A}(\mu)$ sensitive to the tail behaviour of $\mu$. Indeed, under the Prohorov metric, or equivalently under any metric inducing the weak topology on $\mathcal{M}$, like the Lévy metric, two distributions $\mu$ and $\nu$ may possess a different tail behaviour but be rather close in metric terms. In this case, qualitative robustness would essentially prevent $R_\mathcal{A}$ from discriminating across different tail profiles. For more details about the Prohorov and Lévy metric we refer to Section 11.3 in [5].

Based on [14], the same authors introduced in [15] the *index of qualitative robustness* for a risk measure $\rho_\mathcal{A}$ defined by

$$\text{iqr}(\rho_\mathcal{A}) := \left( \inf\{p \in [1, \infty) ; \text{ } R_\mathcal{A} \text{ is } p\text{-robust on } \mathcal{M}_\infty \} \right)^{-1}.$$

By combining Theorem 2.16 in [15] and our previous Theorem 4.3 we obtain the following interesting result relating the qualitative robustness of the operator $R_\mathcal{A}$ to the topological properties of the acceptance set $\mathcal{A}$. 

9
Theorem 5.3. Assume $\mathcal{A} \subset L^\infty$ is a convex, law-invariant acceptance set, and let $1 \leq p < \infty$. The following statements are equivalent:

(a) $R_\mathcal{A}$ is $p$-robust on $M_\infty$;
(b) $\text{cl}_p(\mathcal{A})$ has nonempty interior in $L^p$.

Moreover, we have
\[
iqr(\rho_\mathcal{A}) = \frac{1}{\text{fin}(\rho_\mathcal{A})}.
\]

(29)

In the final sections we compute the index of finiteness of several risk measures. As a consequence of the above theorem, these examples turn out to be important also from the perspective of qualitative robustness.

6 Risk measures based on utility functions

In this section we analyse the index of finiteness of risk measures based on expected utility. Note that, even though such risk measures are treated in [15], no results concerning their statistical robustness are proved there.

Recall that a nonconstant function $u : \mathbb{R} \to \mathbb{R} \cup \{-\infty\}$ is said to be a utility function if $u$ is increasing and concave. This implies that $u$ is unbounded from below. In the sequel, we assume that $u$ denotes a utility function which is bounded from above.

For every $1 \leq p \leq \infty$ and a level $\alpha \in \mathbb{R}$ we set
\[
\mathcal{A}_u^p := \{X \in L^p ; \mathbb{E}[u(X)] \geq \alpha\}.
\]

(30)

Clearly, this set is nonempty if and only if $u(x) \geq \alpha$ for some $x \in \mathbb{R}$, which we assume from now on. Moreover, in that case $\mathcal{A}_u^p$ is a convex, law-invariant acceptance set.

We start by providing a characterization of when risk measures of the form $\rho_{\mathcal{A}_u^\infty,S}$ are finite-valued on $L^\infty$.

Proposition 6.1. Let $S = (S_0, S_T)$ be a traded asset with $S_T \in L^\infty$.

(i) Assume $u$ never attains the value $-\infty$ and $u(x) > \alpha$ for some $x \in \mathbb{R}$. Then the following are equivalent:

(a) $\rho_{\mathcal{A}_u^\infty,S}$ is finite-valued and, hence, continuous on $L^\infty$;
(b) $P(S_T = 0) = 0$.

(ii) Assume $u$ attains the value $-\infty$ or $u(x) \leq \alpha$ for all $x \in \mathbb{R}$. Then the following are equivalent:

(a) $\rho_{\mathcal{A}_u^\infty,S}$ is finite-valued and, hence, continuous on $L^\infty$;

(b) \( \mathbb{P}(S_T \geq \varepsilon) = 1 \) for some \( \varepsilon > 0 \).

Proof. First, we show that \( \rho_{\mathcal{A}_u},S \) never takes the value \(-\infty\). To this end, fix \( X \in L^\infty \) and \( \gamma > 0 \) such that \( \mathbb{P}(S_T \geq \gamma) > 0 \). Then, since \( u \) is unbounded from below, we can always find \( \lambda > 0 \) sufficiently large to yield
\[
\mathbb{E}[u(X - \lambda S_T)] \leq u(\|X\|_\infty - \lambda \gamma) \mathbb{P}(S_T \geq \gamma) + \sup_{x \in \mathbb{R}} u(x) \mathbb{P}(S_T < \gamma) < \alpha. \tag{31}\]
This implies \( X - \lambda S_T \notin \mathcal{A}_u^{\infty} \) and, hence, \( \rho_{\mathcal{A}_u},S(X) > -\infty \).

To prove (i), assume first that (a) holds so that \( \rho_{\mathcal{A}_u},S(-\xi 1_\Omega) < \infty \) for any \( \xi > 0 \). As a result, for every \( \xi > 0 \) there exists \( \lambda > 0 \) such that
\[
u(-\xi) \mathbb{P}(S_T = 0) + \sup_{x \in \mathbb{R}} u(x) \mathbb{P}(S_T > 0) \geq \mathbb{E}[u(-\xi 1_\Omega + \lambda S_T)] \geq \alpha. \tag{32}\]

Since \( u \) is unbounded below, this is only possible if \( \mathbb{P}(S_T = 0) = 0 \), proving (b).

Now assume (b) holds and take \( X \in L^\infty \). Since \( u(x) > \alpha \) for some \( x \in \mathbb{R} \) and \( \mathbb{P}(S_T = 0) = 0 \), we can find \( \varepsilon > 0 \) sufficiently small to obtain
\[
\mathbb{E} \left[ u \left( X + \frac{1}{\varepsilon^2} S_T \right) \right] \geq u \left( \frac{1}{\varepsilon} - \|X\|_\infty \right) \mathbb{P}(S_T \geq \varepsilon) + u(-\|X\|_\infty) \mathbb{P}(S_T < \varepsilon) \geq \alpha, \tag{33}\]
implying that \( \rho_{\mathcal{A}_u},S(X) < \infty \). Hence, (a) follows since \( \rho_{\mathcal{A}_u},S \) never attains the value \(-\infty\).

To prove (ii), we first show that (b) always implies (a). Indeed, if (b) holds then \( S_T \) is an interior point of \( L^\infty \), hence \( \rho_{\mathcal{A}_u},S \) is finite-valued by Proposition 3.1 in [8].

Conversely, assume that (a) holds under the condition that \( u(-\xi) = -\infty \) for some \( \xi > 0 \). In this case, set \( X := (-\xi - 1)1_\Omega \) and note that for every \( \lambda > 0 \) there exists \( \varepsilon > 0 \) such that \( u(-\xi - 1 + \lambda \varepsilon) = -\infty \).

Now, if \( \mathbb{P}(S_T < \varepsilon) > 0 \) for all \( \varepsilon > 0 \), this implies
\[
\mathbb{E}[u(X + \lambda S_T)] \leq u(-\xi - 1 + \lambda \varepsilon) \mathbb{P}(S_T < \varepsilon) + \sup_{x \in \mathbb{R}} u(x) \mathbb{P}(S_T \geq \varepsilon) < \alpha. \tag{34}\]

As a result \( \rho_{\mathcal{A}_u},S(X) = \infty \), contradicting (a). Hence, we must have \( \mathbb{P}(S_T \geq \varepsilon) > 0 \) for some \( \varepsilon > 0 \) so that (b) holds.

Finally, assume that (a) holds and \( u \) is bounded from above by \( \alpha \), and set \( x_0 := \inf\{x \in \mathbb{R}; u(x) = \alpha\} \). Moreover, take \( \xi > -x_0 \). Since \( \rho_{\mathcal{A}_u},S(-\xi 1_\Omega) < \infty \), there exists \( \lambda > 0 \) such that \( \mathbb{E}[u(-\xi 1_\Omega + \lambda S_T)] \geq \alpha \). But this is only possible if \( -\xi + \lambda S_T \geq x_0 \) almost surely, implying that \( \mathbb{P}(S_T \geq \frac{x_0 - x_0}{\lambda}) = 1 \). As a consequence (b) holds, concluding the proof. \( \square \)

To study extension properties of risk measures based on expected utility, we first need to investigate the topological structure of the corresponding acceptance sets.

**Lemma 6.2.** For every \( 1 \leq p \leq \infty \), the acceptance set \( \mathcal{A}_u^p \) is closed in \( L^p \).
Proof. To prove that $\mathcal{A}_u^p$ is closed in $L^p$, take a sequence $(X_n)$ in $\mathcal{A}_u^p$ and assume $X_n \to X$ in $L^p$ as $n \to \infty$. Since $X_n \to X$ almost surely as $n \to \infty$, up to passing to a suitable subsequence, it follows from the continuity of $u$ and by Fatou’s lemma, e.g. Lemma 4.3.3 in [5], that

$$
E[u(X)] = E[\lim u(X_n)] \geq \limsup E[u(X_n)] \geq \alpha.
$$

(35)

This shows that $X \in \mathcal{A}_u^p$ and, hence, that $\mathcal{A}_u^p$ is closed. \qed

Assume $S = (S_0, S_T)$ is a traded asset with $S_T \in L^\infty$ such that $\rho_{\mathcal{A},S}$ is finite-valued and fix $1 \leq p < \infty$. Then by Theorem 4.3 we know that $\rho_{\mathcal{A},S}$ can be extended to a finite-valued, continuous risk measure on $L^p$ if and only if $\text{cl}_p(\mathcal{A}_u^\infty)$ has nonempty interior in $L^p$. Since, by the above lemma, $\text{cl}_p(\mathcal{A}_u^\infty) \subset \mathcal{A}_u^p$ we infer that if $\mathcal{A}_u^p$ has empty interior, then $\rho_{\mathcal{A},S}$ cannot admit such an extension. The result below provides conditions for $\mathcal{A}_u^p$ to have empty interior. In particular, condition (ii) shows that this may depend on the decay behaviour of the utility function at $-\infty$.

**Lemma 6.3.** Fix $1 \leq p < \infty$ and assume one of the following conditions:

(i) $u(x) \leq \alpha$ for all $x \in \mathbb{R}$;

(ii) $\lim_{x \to \infty} \frac{u(x)}{u(-x)} = 0$.

Then $\mathcal{A}_u^p$ has empty interior in $L^p$.

Proof. (i) Take $X \in \mathcal{A}_u^p$ and $r > 0$. Choose first $\gamma > 0$ with $\mathbb{P}(|X| < \gamma) > 0$ and then $\xi > 0$ such that $u(\gamma - \xi) < \alpha$. Since $(\Omega, \mathcal{F}, \mathbb{P})$ is nonatomic we find $A \subset \{|X| < \gamma\}$ with $\mathbb{P}(A) < \frac{r^p}{\xi^p}$. Set now $Y := (X - \xi)1_A + X1_{A^c}$, and note that $\|X - Y\|_p = \xi^p\mathbb{P}(A) < r^p$. Moreover,

$$
E[u(Y)] = E[u(X - \xi)1_A] + E[u(X)1_{A^c}] \leq u(\gamma - \xi)\mathbb{P}(A) + \alpha\mathbb{P}(A^c) < \alpha.
$$

(36)

Hence, in every neighborhood of $X$ there exists some element which does not belong to $\mathcal{A}_u^p$. Since $X$ was arbitrary, this implies $\mathcal{A}_u^p$ has empty interior.

(ii) Take $X \in \mathcal{A}_u^p \cap L^\infty$ so that $u(\|X\|_\infty) \geq E[u(X)] \geq \alpha$, and fix $r > 0$. It is easy to see that by assumption we can find a sufficiently large $\xi > 0$ such that

$$
0 \leq \frac{u(\|X\|_\infty) - \alpha}{u(\|X\|_\infty) - u(\|X\|_\infty - \xi)} < \frac{r^p}{\xi^p} < 1.
$$

(37)

As a consequence, taking $\lambda \in (0,1)$ with

$$
\frac{u(\|X\|_\infty) - \alpha}{u(\|X\|_\infty) - u(\|X\|_\infty - \xi)} < \lambda < \frac{r^p}{\xi^p}
$$

(38)

we obtain $\xi^p\lambda < r^p$ and

$$
\lambda u(\|X\|_\infty - \xi) + (1 - \lambda)u(\|X\|_\infty) < \alpha.
$$

(39)
Since \( (\Omega, \mathcal{F}, \mathbb{P}) \) is nonatomic, \( \mathbb{P}(A) = \lambda \) for a suitable \( A \in \mathcal{F} \). Now, consider the random variable \( Y := (X - \xi)1_A + X1_{A^c} \). Clearly, \( \|X - Y\|_p^p = \xi^p \mathbb{P}(A) < r^p \). Moreover, as a consequence of \( (39) \), we obtain
\[
\mathbb{E}[u(Y)] \leq \mathbb{P}(A)u(\|X\|_\infty - \xi) + \mathbb{P}(A^c)u(\|X\|_\infty) < \alpha.
\] (40)
This implies that \( X \) is not an interior point of \( \mathcal{A}_u^p \). As a result, by the density of \( L^\infty \) in \( L^p \) we can conclude that \( \mathcal{A}_u^p \) has empty interior. \( \square \)

The following result follows immediately from the discussion preceding Lemma 6.3.

**Corollary 6.4.** Assume that either \( u(x) \leq \alpha \) for all \( x \in \mathbb{R} \) or that \( u \) attains the value \(-\infty\). Then, for any traded asset \( S = (S_0, S_T) \) with \( S_T \in L^\infty \) such that \( \rho_{\mathcal{A}_u^\infty, S} \) is finite-valued on \( L^\infty \), we have \( \text{fin}(\rho_{\mathcal{A}_u^\infty, S}) = \infty \).

**Remark 6.5.** As an example of a utility function attaining the value \(-\infty\) we can consider a capped log-utility of the form
\[
u(x) := \begin{cases} 
C & \text{if } x \geq c \\
\log(1 + x) & \text{if } 0 \leq x < c \\
-\infty & \text{if } x < 0
\end{cases}
\] (41)
for fixed constants \( c > 0 \) and \( C = \log(1 + c) \).

In view of Corollary 6.4, we assume for the rest of this section that \( u \) is finite-valued and \( u(x) > \alpha \) for some \( x \in \mathbb{R} \). Under this assumption, we can refine Theorem 4.3 as follows.

**Theorem 6.6.** (i) For any \( 1 \leq p < \infty \) we have \( \text{cl}_p(\mathcal{A}_u^\infty) = \mathcal{A}_u^p \).
(ii) Let \( S = (S_0, S_T) \) be a traded asset with \( S_T \in L^\infty \). Assume \( \rho_{\mathcal{A}_u^\infty, S} \) is finite-valued and, hence, continuous on \( L^\infty \), and fix \( 1 \leq p < \infty \). The following statements are equivalent:
\[ \begin{align*}
(a) & \quad \rho_{\mathcal{A}_u^\infty, S} \text{ can be extended to a finite-valued and, hence, continuous risk measure on } L^p; \\
(b) & \quad \mathcal{A}_u^p \text{ has nonempty interior in } L^p.
\end{align*} \]
In this case, the extension is unique and given by \( \rho_{\mathcal{A}_u^\infty, S} \).

**Proof.** By virtue of Theorem 4.3 it is enough to show part (i). To this end, since \( \mathcal{A}_u^p \) is closed by Lemma 6.2, we only need to prove that any element \( X \in \mathcal{A}_u^p \) is the limit in \( L^p \) of a suitable sequence \( (X_n) \) of elements in \( \mathcal{A}_u^\infty \). Now, take \( X \in \mathcal{A}_u^p \).

Since there exists \( x \in \mathbb{R} \) such that \( u(x) > \alpha \), we can find \( Y \in L^p \) with \( \mathbb{E}[u(Y)] > \alpha \). Then, setting \( Z_\lambda := \lambda X + (1 - \lambda)Y \) for \( \lambda \in (0, 1) \), the concavity of \( u \) yields
\[
\mathbb{E}[u(Z_\lambda)] \geq \lambda \mathbb{E}[u(X)] + (1 - \lambda)\mathbb{E}[u(Y)] > \alpha.
\] (42)
Since \( Z_\lambda \to X \) in \( L^p \) as \( \lambda \to 1 \), this shows we may assume that \( \mathbb{E}[u(X)] > \alpha \) without loss of generality.

Now, assume \( X \) is bounded from below almost surely, and set \( X_n := X1_{\{X \leq n\}} \in L^\infty \) for any \( n \in \mathbb{N} \). Then
\[
\alpha < \mathbb{E}[u(X)] = \mathbb{E}[u(X_n)] + \mathbb{E}[u(X1_{\{X > n\}})].
\] (43)
Since $u$ is bounded from above, we have $\mathbb{E}[u(X_1|X>n)] \to 0$ as $n \to \infty$ by dominated convergence, hence $\mathbb{E}[u(X_n)] > \alpha$ for large enough $n \in \mathbb{N}$. In particular, we eventually have $X_n \in \mathcal{A}_u^\infty$. This shows that $X \in \text{cl}_p(\mathcal{A}_u^\infty)$ because $X_n \to X$ in $L^p$ as $n \to \infty$.

Finally, assume $X$ is not bounded from below almost surely and define for each $n \in \mathbb{N}$ the random variable $X_n := X1_{\{X \geq -n\}} \in L^p$. Clearly, $X_n \to X$ in $L^p$ as $n \to \infty$. Moreover, $\mathbb{E}[u(X_n)] \geq \mathbb{E}[u(X)] > \alpha$ for all $n \in \mathbb{N}$ by the monotonicity of $u$. Since every $X_n$ is bounded from below almost surely, we can rely on the previous argument and conclude that $X_n \in \text{cl}_p(\mathcal{A}_u^\infty)$ for any $n \in \mathbb{N}$ so that $X \in \text{cl}_p(\mathcal{A}_u^\infty)$.

**Exponential utility**

The index of finiteness may be $\infty$ even if $u$ never attains the value $-\infty$. To see this we consider the exponential utility function

$$u(x) := 1 - e^{-\gamma x}, \quad x \in \mathbb{R},$$

for some fixed $\gamma > 0$. The following result shows that finite-valued risk measures on $L^\infty$ based on expected exponential utility do not admit finite-valued, hence continuous, extensions to any $L^p$ space, $1 \leq p < \infty$.

**Corollary 6.7.** Let $S = (S_0,S_T)$ be a traded asset with $S_T \in L^\infty$, and assume $\rho_{\mathcal{A}_u^\infty,S}$ is finite-valued. Then $\text{fin}(\rho_{\mathcal{A}_u^\infty,S}) = \infty$.

**Proof.** For any $1 \leq p < \infty$ we have

$$\lim_{x \to \infty} \frac{x^p}{u(-x)} = \lim_{x \to \infty} \frac{x^p}{1 - e^{-\gamma x}} = 0.$$  \hspace{1cm} (44)

Hence, Lemma 6.3 implies that the interior of $\mathcal{A}_u^p$ is empty, thus $\rho_{\mathcal{A}_u^\infty,S}$ does not admit any finite-valued, continuous extension to $L^p$ by Theorem 6.6.

**Flat power utility**

We now show that we can find convex risk measures on $L^\infty$ whose index of finiteness is equal to any prescribed number $1 \leq q < \infty$. To this effect recall that the flat power utility function is defined by

$$u(x) := \begin{cases} -|x|^q & \text{if } x < 0 \\ 0 & \text{if } x \geq 0 \end{cases}$$

where $1 \leq q < \infty$.

**Corollary 6.8.** Let $S = (S_0,S_T)$ be a traded asset with $S_T \in L^\infty$, and assume $\rho_{\mathcal{A}_u^\infty,S}$ is finite-valued. Then $\text{fin}(\rho_{\mathcal{A}_u^\infty,S}) = q$ and the index is attained.

**Proof.** First, note that

$$\mathbb{E}[u(X)] = -\|X \wedge 0\|_q^q \quad \text{for all } X \in L^1.$$  \hspace{1cm} (46)

Since we assumed that $u(x) > \alpha$ for some $x \in \mathbb{R}$, this implies $\alpha < 0$ in the present case.

For $p \geq q$ the map $U : L^p \to \mathbb{R}$ defined by

$$U(X) := \mathbb{E}[u(X)] \quad \text{for } X \in L^p$$

for $p \geq q$ the map $U : L^p \to \mathbb{R}$ defined by

$$U(X) := \mathbb{E}[u(X)] \quad \text{for } X \in L^p$$

14
is easily seen to be continuous. Since $A_p$ contains the nonempty, open set $U^{-1}(\alpha, \infty)$, it must have nonempty interior, hence fin$(\rho_{A_{\infty}} S) \leq q$ by Theorem 6.6. In particular, note that $\rho_{A_{\infty}} S$ can be extended to a finite-valued, continuous risk measure on $L^q$.

If $p < q$, then it is immediate to see that

$$\lim_{x \to \infty} \frac{x^p}{u(-x)} = \lim_{x \to \infty} x^{p-q} = 0.$$  \hspace{1cm} (48)

Consequently, the interior of $A_p$ is empty by Lemma 6.3, hence fin$(\rho_{A_{\infty}} S) \geq q$ as a consequence of Theorem 6.6. In conclusion, fin$(\rho_{A_{\infty}} S) = q$ and the index is attained. \hfill \Box

**An example of a non-HARA utility**

In this section we focus on the utility function

$$u(x) := \begin{cases} C & \text{if } x \geq c \\ \frac{1}{a} (1 + ax - \sqrt{1 + a^2 x^2}) & \text{if } x < c \end{cases}$$ \hspace{1cm} (49)

for fixed parameters $a > 0$ and $c \geq 0$, and $C = \frac{1}{a} (1 + ac - \sqrt{1 + a^2 c^2})$. The uncapped version was proposed in Section 2.2.2 in [13] as a tractable alternative to exponential utility if one wants to penalize negative wealth less severely. The following result shows that the corresponding risk measures can always be extended to $L^1$.

**Corollary 6.9.** Let $S = (S_0, S_T)$ be a traded asset with $S_T \in L^\infty$, and assume $\rho_{A_{\infty}} S$ is finite-valued. Then fin$(\rho_{A_{\infty}} S) = 1$ and the index is attained.

**Proof.** Define the map $U : L^1 \to \mathbb{R}$ by setting

$$U(X) := \mathbb{E}[u(X)] \quad \text{for } X \in L^1.$$ \hspace{1cm} (50)

Since $U$ is concave and increasing, it is continuous by Theorem 1 in [11]. As a result, $A_p$ has nonempty interior because it contains the nonempty, open set $U^{-1}(\alpha, \infty)$. In conclusion, Theorem 6.6 implies that fin$(\rho_{A_{\infty}} S) = 1$ and the index is clearly attained. \hfill \Box

**7 Max-correlation risk measures**

In this section we provide a characterization of the index of finiteness for the so-called max-correlation risk measure introduced by Rüschendorf in [17] and studied by Ekeland and Schachermayer in [6] and by Ekeland, Galichon, and Henry in [7].

Consider a probability measure $Q$ on $(\Omega, \mathcal{F})$ that is absolutely continuous with respect to $P$. Assume that $1 \leq p \leq \infty$ is such that $\frac{dQ}{dP} \in L^p$ and define the max-correlation risk measure $\rho_{Q,p} : L^p \to \mathbb{R} \cup \{\infty\}$ by

$$\rho_{Q,p}(X) := \sup \left\{ \mathbb{E}[-XY] ; \ Y \sim \frac{dQ}{dP} \right\} \quad \text{for } X \in L^p.$$ \hspace{1cm} (51)
As a consequence of Theorem 13.4 in [3], for any $X \in L^\infty$ we have the equivalent (and more common) formulation

$$\rho_{Q,p}(X) := \sup_{X' \sim X} \mathbb{E}_Q[-X'] \quad \text{for } X \in L^p. \quad (52)$$

The acceptance set associated with $\rho_{Q,p}$ is given by

$$A_{\rho_{Q,p}} := \{ X \in L^p ; \rho_{Q,p}(X) \leq 0 \} = \{ X \in L^p ; \mathbb{E}[XY] \geq 0, \forall Y \sim \frac{dQ}{dP} \}.$$  \quad (53)

Clearly, $A_{\rho_{Q,p}}$ is law-invariant and coherent, i.e. a convex cone.

We start by showing when the risk measure $\rho_{Q,\infty,S}$ is finite-valued on $L^\infty$.

**Proposition 7.1.** Let $S = (S_0, S_T)$ be a traded asset with $S_T \in L^\infty$. The following are equivalent:

(a) $\rho_{Q,\infty,S}$ is finite-valued and, hence, continuous on $L^\infty$;

(b) $\inf_{Z \sim S_T} \mathbb{E}_Q[Z] > 0$.

**Proof.** Since $A_{\rho_{Q,\infty}}$ is coherent, it follows from Proposition 3.6 and Theorem 3.16 in [3] that (a) is equivalent to $S_T$ being an interior point of $A_{\rho_{Q,\infty}}$. By the continuity of the cash-additive risk measure $\rho_{Q,\infty}$, this is equivalent to $\rho_{Q,\infty}(S_T) < 0$, concluding the proof. \qed

Before proving the extension result for max-correlation risk measures, we need the following lemma.

**Lemma 7.2.** Let $1 \leq p \leq \infty$ and assume that $\frac{dQ}{dP} \in L^{p'}$. Then $\rho_{Q,p}$ is finite-valued and, hence, continuous on $L^p$.

**Proof.** For $X \in L^p$ we have

$$|\rho_{Q,p}(X)| \leq \|X\|_p \left\| \frac{dQ}{dP} \right\|_{p'} \quad (54)$$

so that $\rho_{Q,p}$ is finite-valued on $L^p$. Moreover, for any $X,Y \in L^p$ we have $\rho_{Q,p}(X) \leq \rho_{Q,p}(X-Y) + \rho_{Q,p}(Y)$ by subadditivity and, consequently,

$$|\rho_{Q,p}(X) - \rho_{Q,p}(Y)| \leq \|X-Y\|_p \left\| \frac{dQ}{dP} \right\|_{p'}.$$ \quad (55)

It follows that $\rho_{Q,p}$ is Lipschitz-continuous on $L^p$. \qed

We now characterize for which $1 \leq p < \infty$ the risk measure $\rho_{Q,\infty}$ admits a finite-valued, continuous extension to $L^p$.

**Proposition 7.3.** For $1 \leq p < \infty$ the following holds:

(i) If $\frac{dQ}{dP} \in L^{p'}$, then $\rho_{Q,\infty}$ admits a unique finite-valued, continuous extension to $L^p$ which is given by $\rho_{Q,p}$. 

16
(ii) If $\frac{dQ}{dP} \notin L^p$, then $\rho_{Q,\infty}$ does not admit finite-valued, continuous extensions to $L^p$.

Proof. Since (i) follows readily from the preceding lemma, we only need to prove (ii). Assume that $\rho_{Q,\infty}$ admits a finite-valued and, hence continuous extension to $L^p$. Since $\mathcal{A}_Q^\infty$ is closed, Theorem 4.3 implies that it must have nonempty interior with respect to the $L^p$-topology. Consider now the linear functional $V : L^\infty \rightarrow \mathbb{R}$ defined by

$$V(X) := E_Q[X] \quad \text{for } X \in L^\infty.$$  

(56)

Note that $A^\infty_Q \subset V^{-1}([0, \infty))$ implies that $V^{-1}([0, \infty))$ has nonempty interior with respect to the $L^p$-topology. Therefore, $V$ is continuous with respect to that topology. As a result, there exists a continuous, linear functional $\overline{V} : L^p \rightarrow \mathbb{R}$ extending $V$. In particular, we can find $Z \in L^\delta_p$ such that

$$E[XZ] = \overline{V}(X) = V(X) = E_Q[X] \quad \text{for all } X \in L^\infty,$$

implying $\frac{dQ}{dP} = Z$ almost surely. Hence, $\frac{dQ}{dP} \in L^\delta_p$ contradicting the assumption. Consequently, $\rho_{Q,\infty}$ does not admit any finite-valued and, hence, continuous extension to $L^p$. □

Set now

$$q := \sup \left\{ p' \in [1, \infty); \frac{dQ}{dP} \in L^{p'} \right\}.$$  

(58)

The following result characterizes the index of finiteness of $\rho_{\mathcal{A}_Q^\infty,S}$. For $\rho_{Q,\infty}$, it is an immediate consequence of Proposition 7.3. The extension in the case of a general traded asset is ensured by Remark 4.5.

Corollary 7.4. Let $S = (S_0, S_T)$ be a traded asset with $S_T \in L^\infty$, and assume $\rho_{\mathcal{A}_Q^\infty,S}$ is finite-valued. Then $\text{fin}(\rho_{\mathcal{A}_Q^\infty,S}) = q'$ and the index is attained if and only if $\frac{dQ}{dP} \in L^q$.

Remark 7.5. It is known that the max-correlation risk measure is a distortion risk measure, see e.g. Remark 2.6 in [17]. Therefore, an alternative strategy to prove Corollary 7.4 would be to use the results in the next section. However, the above proof is more direct and simpler.

8 Distortion risk measures

In this section we rely on the results for cash-additive distortion risk measures obtained in [15] and derive the corresponding index of finiteness for general risk measures which need not be cash-additive.

Let $\delta : [0, 1] \rightarrow [0, 1]$ be a concave, increasing function satisfying $\delta(0) = 0$ and $\delta(1) = 1$. For $X \in L^\infty$ we denote by $F_X$ the distribution function of $X$. The corresponding distortion risk measure is the map $\rho_\delta : L^\infty \rightarrow \mathbb{R}$ defined by

$$\rho_\delta(X) := \int_{-\infty}^0 \delta(F_X(x))dx - \int_0^\infty (1 - \delta(F_X(x)))dx \quad \text{for } X \in L^\infty.$$  

(59)

We refer to Section 4.6 in [11] for more details about this type of risk measures. As it is well-known, $\rho_\delta$ is a coherent, law-invariant, cash-additive risk measure, hence the corresponding acceptance set

$$\mathcal{A}_\delta := \{X \in L^\infty; \rho_\delta(X) \leq 0\}$$  

(60)
is law-invariant and coherent.

First, we characterize when general risk measures associated to the acceptance set $\mathcal{A}_\delta$ are finite-valued on $L^\infty$.

**Proposition 8.1.** Let $S = (S_0, S_T)$ be a traded asset with $S_T \in L^\infty$. The following are equivalent:

(a) $\rho_{\mathcal{A}_\delta, S}$ is finite-valued and, hence, continuous on $L^\infty$;

(b) $\delta(F_{S_T}(x)) < 1$ for some $x > 0$.

In particular, if $\delta$ is strictly increasing on some left neighborhood of 1, then (a) holds.

**Proof.** First, note that $\mathcal{A}_\delta$ has nonempty interior in $L^\infty$ because it contains a translate of $L^\infty_+$ by monotonicity, and the corresponding interior points are those $X \in L^\infty$ satisfying $\rho_{\mathcal{A}_\delta}(X) < 0$. By combining Proposition 3.6 and Theorem 3.16 in [8], it follows that $\rho_{\mathcal{A}_\delta, S}$ is finite-valued on $L^\infty$ if and only if $S_T$ belongs to the interior of $\mathcal{A}_\delta$. As a result, the assertion (a) is then equivalent to

$$\rho_{\mathcal{A}_\delta}(S_T) = -\int_0^\infty (1 - \delta(F_{S_T}(x)))dx < 0,$$

which, in turn, is equivalent to (b) by virtue of the monotonicity of $\delta$. □

Now, define

$$q := \sup \left\{ p \in [1, \infty) ; \int_0^1 (\delta'_+(\lambda))^p d\lambda < \infty \right\}$$

(62)

where $\delta'_+$ denotes the right derivative of $\delta$.

The following result follows directly from Proposition 2.22 in [15] combined with Remark 4.5.

**Proposition 8.2.** Let $S = (S_0, S_T)$ be a traded asset with $S_T \in L^\infty$, and assume $\rho_{\mathcal{A}_\delta, S}$ is finite-valued. Then $\text{fin}(\rho_{\mathcal{A}_\delta, S}) = q'$ and the index is attained if and only if $\int_0^1 (\delta'_+(\lambda))^p d\lambda < \infty$.

**Example 8.3.** Let $S = (S_0, S_T)$ be a traded asset with $S_T \in L^\infty$, and assume the corresponding risk measure $\rho_{\mathcal{A}_\delta, S}$ is finite-valued over $L^\infty$. The following distortion functions are discussed in [2]; see also [15].

The MAXVAR risk measure corresponds to the distortion function

$$\delta(x) = x^{\frac{1}{\gamma}} \quad \text{for } x \in [0, 1] \text{ and } \gamma \geq 1.$$  

(63)

A direct computation shows that $\text{fin}(\rho_{\mathcal{A}_\delta, S}) = \gamma$ and that the index is not attained.

Similarly, the MINVAR risk measure corresponds to

$$\delta(x) = 1 - (1 - x)^{\gamma} \quad \text{for } x \in [0, 1] \text{ and } \gamma \geq 1.$$  

(64)

In this case, $\text{fin}(\rho_{\mathcal{A}_\delta, S}) = 1$ and the index is attained.
The MAXMINVAR risk measure is associated to the distortion
\[ \delta(x) = (1 - (1 - x)\gamma)\frac{1}{\gamma} \quad \text{for } x \in [0, 1] \text{ and } \gamma \geq 1. \] (65)

Since \( \delta'(x) \sim (\gamma x)^{\frac{1}{\gamma} - 1} \) for \( x \to 0 \), it follows that \( \text{fin}(\rho_{\delta, S}) = \gamma \) and the index is not attained.

Similarly, the MINMAXVAR risk measure corresponding to
\[ \delta(x) = \left(1 - (1 - x)^\frac{1}{\beta}\right)^\gamma \quad \text{for } x \in [0, 1] \text{ and } \gamma \geq 1 \] (66)
is such that \( \text{fin}(\rho_{\delta, S}) = \gamma \), and the index is not attained.

We can also consider the distortion
\[ \delta(x) = \left(1 - (1 - x)^\frac{1}{\beta}\right)^\gamma \quad \text{for } x \in [0, 1] \text{ and } \beta, \gamma \geq 1. \] (67)

In this case \( \text{fin}(\rho_{\delta, S}) = \beta \), in accordance with Example 2.23 in [15], and the index is not attained.

**Example 8.4.** Consider a distortion function of the form
\[ \delta(x) = \frac{1}{\log(2)} \log(1 + x) \quad \text{for } x \in [0, 1]. \] (68)

Then it is immediate to see that \( \text{fin}(\rho_{\delta, S}) = 1 \) and that the index is attained.
