It is well established that the superconductivity in the recently discovered superconducting compound MgB$_{2}$ resides in the quasi-two-dimensional band ($\sigma$-band) and three-dimensional band ($\pi$-band). We demonstrate that, due to such band structure, the anisotropic Ginzburg-Landau theory practically does not have region of applicability, because gradient expansion in the $c$ direction breaks down. In the case of dirty $\pi$-band we derive the simplest equations which describe properties of such superconductors near $T_{c}$ and explore some consequences of these equations.

Ginzburg-Landau (GL) theory is the most powerful and widely used phenomenological theory of superconductivity (see, e.g., Refs. 1, 2). It describes practically all known superconductors in the vicinity of transition temperature. GL theory is fully microscopically justified and its all parameters can be derived from the microscopic BCS theory 3. GL theory provides the basis for such elaborated fields as vortex physics 4 and the theory of fluctuation phenomena 5.

The recently discovered superconductor MgB$_{2}$ 3 gives an example of a superconductor which is not described by the anisotropic GL theory. This very unusual feature is a consequence of a specific band structure of this compound. It is reliably established that superconductivity in MgB$_{2}$ resides in two families of bands: strongly superconducting quasi-two-dimensional $\sigma$-bands and weakly superconducting three-dimensional $\pi$-bands (see, e.g., Ref. 6). Both bands are characterized by their intrinsic coherence lengths, and the $c$ axis coherence length in the $\sigma$-band is much smaller than $c$ axis coherence length in the $\pi$-band. Typically, the strong band forces the order parameter in the weak band to change in the $c$ direction at distances smaller than the intrinsic $c$ axis coherence length in this band. This means that almost in the whole temperature range the effective coherence length in the $c$ direction, $\xi_{c}(T)$, is smaller than the intrinsic coherence length in the $\pi$-band, $\xi_{\pi,c}$. The crossover to the GL region takes place only when $\xi_{c}(T)$ exceeds $\xi_{\pi,c}$, which occurs in the very close vicinity of $T_{c}$. In this narrow region the $\pi$-band strongly increases the $c$ axis coherence length. Beyond the narrow region, the variations of the order parameter in the $c$ directions are not described by the anisotropic GL theory. Important consequences of GL theory breakdown are the strong temperature dependence of the $H_{c2}$ anisotropy 7,8,9 and strong deviations of the $\sigma$-band angular dependence from the simple "effective mass" law 10,11.

Obviously, the breakdown of the anisotropic GL theory has numerous consequences and it would be desirable (i) to trace the reason of this breakdown and (ii) to derive the simplest model, which replaces the GL model near $T_{c}$.

This paper addresses these issues. For illustration, we use the simplest microscopic model, multiband generalization of the Usadel theory, describing a dirty two-band superconductor with weak interband scattering 8,12. However, the main conclusions are very general and do not depend much on the intraband scattering strength.

We consider a dirty two-band superconductor with weak interband scattering. Such superconductor is described by Usadel equations for the impurity averaged normal and anomalous Green’s functions, $G_{\alpha}$ and $F_{\alpha}$, $G_{\alpha}^{2}+|F_{\alpha}|^{2}=1$, and the pair potentials $\Delta_{\alpha}$.

$$\omega F_{\alpha}-\sum_{j} \frac{D_{\alpha,j}}{2} [G_{\alpha} D_{\pi}^{2} F_{\alpha}-F_{\alpha}^{*} \nabla_{j}^{2} G_{\alpha}] = \Delta_{\alpha} G_{\alpha}$$

where $\alpha=1,2$, $j=x,y,z$ is the coordinate index, $D_{j}\equiv \nabla_{j}-(2\pi i / \Phi_{0}) A_{j}$, $D_{\alpha,j}$ are diffusion constants, and $\omega=2\pi \tau (s+1/2)$ are Matsubara frequencies. Bearing in mind the application to MgB$_{2}$, in our notations index 1 corresponds to $\sigma$-bands and index 2 to $\pi$-bands, $D_{1,j}\equiv D_{\sigma,j}$ and $D_{2,j}\equiv D_{\pi,j}$. All bands are isotropic in the $xy$ plane, $D_{\alpha,xy}=D_{\alpha,y}$ and anisotropic in the $xz$ plane with the anisotropy ratios $\gamma_{\alpha}=\sqrt{D_{\alpha,x} / D_{\alpha,z}}$. Self-consistency conditions can be written as 12

$$W_{1} \Delta_{1}-W_{12} \Delta_{2}=2\pi T \sum_{\omega>0} \left(F_{1}^{*} - \frac{\Delta_{1}}{\omega} \right)+\Delta_{1} \ln \frac{1}{T}$$

$$-W_{21} \Delta_{1}+W_{2} \Delta_{2}=2\pi T \sum_{\omega>0} \left(F_{2}^{*} - \frac{\Delta_{2}}{\omega} \right)+\Delta_{2} \ln \frac{1}{T}$$

where $t \equiv T / T_{c}$ and the matrix $W_{\alpha\beta}$ is related to the matrix of coupling constants $\Lambda_{\alpha\beta}$ as

$$W_{1} = -\Lambda_{+} + \sqrt{\Lambda_{-}^{2} + \Lambda_{12} \Lambda_{21}}, \quad W_{2} = \frac{-\Lambda_{+} + \sqrt{\Lambda_{-}^{2} + \Lambda_{12} \Lambda_{21}}}{\text{Det}},$$

$$W_{12} = \Lambda_{12} / \text{Det}, \quad W_{21} = \Lambda_{21} / \text{Det},$$

with $\Lambda_{\alpha\beta}$ as

$$\Lambda_{+}=\Lambda_{12} \Lambda_{21}$$

and

$$\Lambda_{-}=\sqrt{\Lambda_{12}^{2} + \Lambda_{21}^{2}.}$$

This expression is obtained by using the complete coupling constants $\Lambda_{\alpha\beta}$ in a fully averaged GL Hamiltonian (see Ref. 13). It can be written in the form of the coupled Usadel equations

$$-\nabla_{c}^{2} - \frac{\Delta_{\alpha}}{2} \nabla_{j}^{2} G_{\alpha} + \Lambda_{\alpha\beta} D_{\beta}^{2} F_{\alpha} = 0$$

and

$$-\nabla_{c}^{2} - \frac{\Delta_{\alpha}}{2} \nabla_{j}^{2} F_{\alpha} + \Lambda_{\alpha\beta} D_{\beta}^{2} G_{\alpha} = 0$$

where $\Lambda_{\alpha\beta}$ are matrix elements of the effective coupling constants $\Lambda_{\alpha\beta}$ and $\Lambda_{\alpha\beta}$ are the pair potentials $\Delta_{\alpha}$. These equations are valid only in the region of applicability of GL theory. In such a region, the GL theory is fully microscopically justified and all its parameters can be derived from the microscopic BCS theory. The crossover to the GL region takes place only when $\xi_{c}(T)$ exceeds $\xi_{\pi,c}$, which occurs in the very close vicinity of $T_{c}$. In this narrow region the $\pi$-band strongly increases the $c$ axis coherence length. Beyond the narrow region, the variations of the order parameter in the $c$ directions are not described by the anisotropic GL theory.
\( \Lambda_\alpha \equiv (\Lambda_1 - \Lambda_2)/2, \ Det \equiv \Lambda_1 \Lambda_2 - \Lambda_1 \Lambda_2, \ W_1 W_2 = W_{12} W_{21}. \) The supercurrent components are given by

\[
j_j = 4\pi e c T \sum \alpha \sum_{\omega > 0} N_\alpha D_{\alpha j} \text{Im} \left[ F_\alpha^* D_j F_\alpha \right], \tag{3}\]

where \( N_\alpha \) are the partial densities of states.

We start with the derivation of the GL equations from the Usadel equations in the close vicinity of \( T_c \) following a standard route. In the lowest approximation \( G^{(0)} = 1 \) and \( F^{(0)} \approx \Delta_\alpha/\omega. \) When \( \Delta_\alpha \) are small and change slowly in space (the exact criterion will be derived below) one can keep only the leading nonlinear and gradient corrections

\[
F_\alpha \approx \frac{\Delta_\alpha}{\omega} - \frac{\Delta_\alpha^3}{2\omega^3} + \sum_j \frac{D_{\alpha j}^2}{2\omega^2} \frac{D^2_j \Delta_\alpha}{N_\alpha} \tag{4}\]

Substituting this expansion into the self-consistency conditions \( 2 \), we obtain coupled GL equations for two gap parameters.

\[
W_1 \Delta_1 - W_2 \Delta_2 = \sum_j \xi_{1j}^2 D_{1j}^2 \Delta_1 - b \Delta_1^3 + \tau \Delta_1 \tag{5a}\]

\[
- W_1 \Delta_1 + W_2 \Delta_2 = \sum_j \xi_{2j}^2 D_{2j}^2 \Delta_2 - b \Delta_2^3 + \tau \Delta_2 \tag{5b}\]

with \( \xi_{\alpha j}^2 = \frac{\pi}{8T} D_{\alpha j}, \) \( b = 7\zeta(3)/(8\pi^2 T^2), \) and \( \tau = \ln(1/t) \approx (T_c - T)/T_c. \)

Near \( T_c \), the right hand sides of Eqs. \( 2 \) are small. This allows us to reduce Eqs. \( 2 \) to a single GL equation by looking for solution for \( \Delta_2 \) in the form

\[
\Delta_2 \approx \frac{W_{21}}{W_2} \Delta_1 + \delta_2, \tag{6}\]

From Eqs. \( 2 \) we obtain

\[
-W_{12} \delta_2 = \sum_j \xi_{1j}^2 D_{1j}^2 \Delta_1 - b \Delta_1^3 + \tau \Delta_1 \tag{7a}\]

\[
W_2 \delta_2 = \sum_j \xi_{2j}^2 D_{2j}^2 \Delta_2 - b \Delta_2^3 + \tau \Delta_2. \tag{7b}\]

The second equation indicates that \( \delta_2 \) is a small correction, \( \delta_2 \ll \Delta_2, \) and one can use \( \Delta_2 \approx (W_{21}/W_2) \Delta_1 \) in the right hand side of this equation. Excluding \( \delta_2 \) and introducing the band-averaged order parameter

\[
\Delta^2 = \frac{W_2 \Delta_2^2 + W_1 \Delta_1^2}{W_2 + W_1} \approx \frac{W_{12} W_2^2 + W_2 W_1^2}{W_{12} W_2 (W_2 + W_1)} \Delta_1^2 \tag{8}\]

we finally obtain the anisotropic GL equation for \( \Delta \)

\[
- \sum_j \xi_{j}^2 D_{j}^2 \Delta + b \Delta^3 - \tau \Delta = 0, \tag{8}\]

with the average coherence lengths

\[
\xi_j^2 = \frac{W_2 \xi_{1j}^2 + W_1 \xi_{2j}^2}{W_2 + W_1}. \tag{9}\]

For the supercurrent, using relation \( W_{21}/W_{12} = \Lambda_{21}/\Lambda_{12} = N_1/N_2, \) we derive

\[
j_j \approx 4e N P \xi_j^2 \text{Im} [\Delta^* D_j \Delta] \tag{10}\]

with \( N \equiv N_1 + N_2 \) and

\[
P \equiv \frac{N_1 N_2 (W_2 + W_1)^2}{(N_1 + N_2) (N_2 W_2^2 + N_1 W_1^2)}. \tag{11}\]

From Eqs. \( 2 \) and \( 1 \) we derive the components of the London penetration depth

\[
\lambda_j^2 \approx \frac{32\pi^2 e N P \xi_j^2}{c\Phi_0}. \tag{12}\]

For the parameters of MgB\(_2\), \( W_1 \ll W_2, \xi_{1z} \ll \xi_{2z}, \xi_{1x} \sim \xi_{2x}, \) the dominating effect of the \( \pi \)-band is the renormalization of the \( c \)-axis lengths

\[
\xi_{1z}^2 \approx \xi_{2z}^2 + S_{12} \xi_{1z}^2, \tag{13}\]

\[
\lambda_{c}^2 \approx \frac{32\pi^2 e N_1}{c\Phi_0} \left( \xi_{1z}^2 + S_{12} \xi_{2z}^2 \right). \tag{14}\]

with \( S_{12} \equiv W_1/W_2 \ll 1. \) The influence of the \( \sigma \)-band on properties not related with the variations of the order parameter along the \( c \) axis are weak and can be treated perturbatively.

We obtain now the applicability criterion for the GL expansion. The gradient expansion is justified if \( -\xi_{\alpha j}^2 \nabla^2 \Delta_\alpha < \Delta_\alpha \) for all \( \alpha \) and \( i. \) Because a typical scale of the spatial variations is the temperature-dependent GL coherence length \( \xi_j(T), \) this condition simply means

\[
\xi_j(T) > \xi_{\alpha j}. \tag{15}\]

The most restraining inequality is the one for \( \alpha = 2 \) and \( i = z \) which gives

\[
(T_c - T)/T_c < \xi_{1z}^2/\xi_{2z}^2 + S_{12} \tag{16}\]

Because \( \xi_{1z} \ll \xi_{2z} \) and \( S_{12} \ll 1, \) the applicability of the GL approach is limited to extremely narrow temperature range near \( T_c, \) i.e., the situation is very different from conventional superconductors. For parameters of MgB\(_2\) this condition implies \( (T_c - T)/T_c \ll 0.05. \) On the other hand, near \( T_c \) the fluctuation effects become important. This means that the mean-field GL theory practically does not have a region of applicability.

We derive now the simplest theory which replaces the GL theory in the conventional GL region \( (T_c - T)/T_c \ll 1. \) As the gradient expansion actually breaks down only for the \( \pi \)-band, in the vicinity of \( T_c \) we can proceed with the expansion \( 6 \) for the \( \sigma \)-band, \( \alpha = 1. \) Substituting this expansion into the self-consistency conditions, we obtain Eq. \( 5a. \) The \( \pi \)-band only weakly renormalizes the nonlinear term and we can use the linear approximation in this band

\[
\omega F_2 - \sum_j \frac{D_{2j}^2}{2} D_j^2 F_2 = \Delta_2. \tag{17}\]

The \( \pi \)-band order parameter can again be represented by Eq. \( 5 \) with \( \delta_2 \) being a small correction. Finding
together with the GL expansion for \( F_1 \), we derive coupled equations for \( \Delta_1 \) and reduced \( \pi \)-band F-function \( f_s, f_s = (2\pi T W_2/W_21) F_2(\omega_s) \) \[26\]

\[
-(1 + S_{12}) \tau \Delta_1 + b \Delta_1^3 - \sum_j \xi_{1,j}^2 D_j^2 \Delta_1 \\
-S_{12} \sum_{s=0}^{\infty} \left( f_s - \frac{\Delta_1}{s + 1/2} \right) = 0, \tag{15a}
\]

\[
(s + 1/2) f_s - \frac{2}{\pi^2} \sum_j \xi_{1,j}^2 D_j^2 f_s = \Delta_1, \tag{15b}
\]

and the expression for the supercurrent

\[ j_j \approx 4e N_1 \xi_{1,j}^2 \text{Im} [\Delta^*_1 D_j \Delta_1] + \frac{8e}{\pi^2} N_1 S_{12} \xi_{1,j}^2 \sum_{s=0}^{\infty} \text{Im} [f_s^* D_j f_s]. \tag{16b} \]

These equations replace the GL equations in the case of dirty \( \pi \)-band. Note that the same equations are also valid in the case of clean \( \sigma \)-band but with different definition of the coherence length \( \xi_{1,j}, \xi_{2,j} = 7 \zeta(3) \left( \langle \psi_{1,j}^2 \rangle / (4\pi T)^2 \right). \]

In the case of weak superconductivity in the \( \pi \)-band, \( S_{12} \ll 1 \), and for \( \xi_{1,1} \ll \xi_{2,1} \), one can neglect the in-plane gradients in the Eq. (15b) and obtain an even simpler set of equations which describe only the dominating strong effects, related to inhomogeneities of the gap parameter along the \( c \) axis, and neglect small renormalizations of the coefficients by the weak \( \pi \)-band

\[
-\tau \Delta_1 + b \Delta_1^3 - \sum_j \xi_{1,j}^2 D_j^2 \Delta_1 \\
-S_{12} \sum_{s=0}^{\infty} \left( f_s - \frac{\Delta_1}{s + 1/2} \right) = 0, \tag{16a}
\]

\[
(s + 1/2) f_s - \frac{2}{\pi^2} \sum_j \xi_{1,j}^2 D_j^2 f_s = \Delta_1, \tag{16b}
\]

\[
j_j \approx 4e N_1 \xi_{1,j}^2 \text{Im} [\Delta^*_1 D_j \Delta_1] + \delta_{1,z} \frac{8e}{\pi^2} N_1 S_{12} \xi_{1,j}^2 \sum_{s=0}^{\infty} \text{Im} [f_s^* D_j f_s], \tag{16c}
\]

We explore now some consequences of these equations. To define an effective coherence length, we consider the response of the order parameter to the weak \( z \)-dependent variation of \( T_c \), \( \tau \rightarrow \tau'(z) = \tau + \delta \tau(z) \). In linear approximation with respect to \( \delta \tau(z) \) Eqs. (16a) and (16b) can be solved by Fourier transform yielding \( \Delta_1 = \Delta_1^0 + \delta \Delta_1(z) \)

\[
\delta \Delta_1(z) = \int G(z - z') \delta \tau(z') \, dz',
\]

\[
G(z) = \int \frac{dk}{2\pi} \frac{\exp(ikz)}{2\tau + \xi_{1,z}^2 k^2 + S_{12} g[(2/\pi^2)\xi_{1,z}^2 k^2]^2],
\]

where \( g(u) = \psi(1/2 + u) - \psi(1/2) \) and \( \psi(u) \) is the digamma-function. In contrast to the GL model, the decay of the perturbation \( \delta \Delta_1(z) \) is not exponential. Using the last equation, one can introduce the effective coherence length \( \xi_z \), which determines the scale of spatial variations of the order parameter in the \( z \) direction,

\[
\xi_{1,z}^2 / \xi_z^2 + S_{12} g \left[ (2/\pi^2) \xi_{1,z}^2 / \xi_z^2 \right] = \tau \tag{17}
\]

The dependence \( \xi_z(T) \) computed from this equation using parameters \( S_{12} = 0.034 \) \[12\] and \( \xi_{1,z}^2 = 300 \xi_z^2 \) is shown in Fig. 1.

FIG. 1: Temperature dependence of the \( c \) axis coherence length, \( \xi_z(T) \) computed from Eq. (17) with parameters \( S_{12} = 0.034 \) and \( \xi_{1,z}^2 = 300 \xi_z^2 \). Marked GL region corresponds to condition \( \xi_z(T) > \xi_{1,z} \equiv \xi_{2,z} \). The inset shows dependence \( \xi_{1,z}^2(T) \) with the dashed line showing the linear GL asymptotic.

The dependence \( \xi_z(T) \) computed from this equation using parameters \( S_{12} = 0.034 \) \[12\] and \( \xi_{1,z}^2 = 300 \xi_z^2 \) is shown in Fig. 1.

Consider the relation between the supercurrent \( j_z \) and supermomentum \( p_z = \nabla_z f - (2\pi/\Phi_0) A_z \), which determines the \( c \) axis London length and depairing current. From Eqs. (16a) and (16b) we obtain

\[
j_z(p_z) = 4e N_1 \Delta_1^2(p_z) p_z \times \left( \xi_{1,z}^2 + \sum_{s=0}^{\infty} (s + 1/2 + (2/\pi^2) (\xi_{1,z} p_z)^2) \right) \Delta_1^2(p_z) = \left( \tau - \xi_{1,z}^2 p_z^2 - S_{12} g \left[ (2/\pi^2) \xi_{1,z}^2 p_z^2 \right] / b \right).
\]

FIG. 2: Left panel: Dependencies \( j_z(p_z) \) at different temperatures for \( S_r = 6 \). The curves are marked by the reduced temperatures \( \tau \xi_{1,z}^2 / \xi_z^2 \), which determines the scaling of the depairing current for the same value of \( S_r \). Right panel: The temperature dependence of the depairing current for the same value of \( S_r \). The dashed curve shows GL dependence.
In the linear regime $j_z \approx (4e\tau N_1/b)\left(\xi_{1,z}^2 + S_{12}\xi_{2,z}^2\right)$, this means that in the whole range $(T_c - T)/T_c \ll 1$ the $z$ component of the London length is given by the GL formula. In conventional superconductors the dependence $j_z(p_z)$ is nonmonotonic and its maximum gives the well-known GL result for depairing current, $j_{dp} = e\Phi_0/(12\sqrt{3}\pi^2\lambda^2\xi) \propto \tau^{3/2}$ for $\tau \to 0$. In our case the situation is different. The amplitude of the order parameter is suppressed at $p_z \sim 1/\xi_z(T)$. However, in the region $\xi_z(T) \ll \xi_{2,z}$ the dependence $j_z(p_z)$ becomes nonlinear at much smaller $p_z$, $p_z \sim 1/\xi_{2,z}$. The shape of this dependence is determined by the parameter $S_r = S_{12}\xi_{2,z}/\xi_{1,z}^2$. The dependencies $j_z(p_z)$ for $S_r = 6$ and different temperatures are plotted in the left panel of Fig. 2. For large values of $S_r$ the dependence $j_z(p_z)$ has two maxima within some temperature range, where first (second) maximum corresponds to the suppression of supercurrent in the $\sigma$-($\pi$)-band. At low temperatures the depairing current $j_{dp}$ is given by the second maximum and is determined mainly by the $\pi$-band. At certain temperature near $T_c$ global maximum switches to the first maximum (see Fig. 2). The temperature dependence of $j_{dp}$ has a kink at this temperature (see the right panel of Fig. 2). For $S_r > 6$ the local maximum of $j_z(p_z)$ at $p_z \sim 1/\xi_{2,z}$ exists even in the limit $\xi_z(T) \ll \xi_{2,z}$.

As another example, we compute from Eqs. the in-plane upper critical field near $T_c$, $H_{c2,\alpha}(T)$. Experiment shows strong upward curvature of $H_{c2,\alpha}(T)$, leading to the temperature dependent anisotropy factor. Microscopic calculations reproduce this feature, both in clean and dirty cases, but require rather heavy numerical computations. Our model allows to trace origin of the upward curvature in a simple way. Selecting the gauge $A_x = H x$ and introducing reduced variables $h = H/H_{c2}^{(1)}$, with $H_{c2}^{(1)} = \Phi_0/(2\pi\xi_1\xi_{1,z})$, $x \propto \sqrt{hr}/\xi_{1,z}$, $r_z = D_{2,z}/D_{1,z}$, we write the linear equation for determination of the upper critical field, $h = H_{c2}/H_{c2}^{(1)}$, as

$$-\frac{S_{12}}{h} \sum_{s=0}^{\infty} \left( \frac{\Delta_1}{s + 1/2} - f_s \right) - \nabla_n^2 \Delta_1 + x^2 \Delta_1 = \frac{\tau}{h} \Delta_1,$$

and

$$(s + 1/2)f_s + \frac{2}{\pi^2} r_z h^2 f_s = \Delta_1.$$

Excluding $f_s$, we obtain the Schroedinger equation for $\Delta_1$ with non-parabolic potential

$$-\nabla_n^2 \Delta_1 + \left( x^2 + \frac{S_{12}}{h} \right) g \left( \frac{2r_z h^2}{\pi^2} \right) \Delta_1 = \frac{\tau}{h} \Delta_1.$$n

Only in the limit $h \ll \sqrt{1 + S_{12}/r_z}/r_z \ll 1$ this equation reduces to the usual oscillator equation. In this limit, using expansion $g(u) \approx (\pi^2/2u)$, we reproduce the GL result, $h_{c2} = \tau/\sqrt{1 + S_{12}/r_z}$. The inequality $h_{c2} \ll \sqrt{1 + S_{12}/r_z}/r_z$ reproduces criterion for the validity of the GL theory. In the opposite limit, $\sqrt{1 + S_{12}/r_z}/r_z \ll h \ll 1$, one can use the asymptotics $g(u) \approx \log(u) + \gamma_E + 2 \log 2$ for $u \gg 1$ with $\gamma_E \approx 0.577$ being the Euler constant, and obtain

$$-\nabla_n^2 \Delta_1 + \left( x^2 + \frac{S_{12}}{h} \log(x^2) \right) \Delta_1 = \alpha(h) \Delta_1,$$

with $C \sim 1$ ($C \approx (8/\pi^2) \exp\left[\log^2(4) + \gamma_E^2\right] = 2/\pi^2$ for $h \gg S_{12})$. In this limit the $\pi$-band gives only small logarithmic correction to the upper critical field. As we can see, the upper critical field has a strong upward curvature in a narrow region near $T_c$: the slope $dh_{c2}/d\tau$ changes from $1/\sqrt{1 + S_{12}/r_z}$ to 1 near $\tau = S_{12} + 1/r_z$, in agreement with microscopic calculations and experiment.

In conclusion, we demonstrated that the properties of magnesium diboride are not described by the anisotropic GL theory. We derived a simple model which replaces this theory in the vicinity of $T_c$, and explored some consequences of this model.

We would like to thank U. Welp for critical reading of the manuscript. This work was supported by the U.S. DOE, Office of Science, under contract # W-31-109-ENG-38.
