Abstract

We consider the longest common subsequence (LCS) problem with the restriction that the common subsequence is required to consist of at least $k$ length substrings. First, we show an $O(mn)$ time algorithm for the problem which gives a better worst-case running time than existing algorithms, where $m$ and $n$ are lengths of the input strings. Furthermore, we mainly consider the LCS in at least $k$ length order-isomorphic substrings problem. We show that the problem can also be solved in $O(mn)$ worst-case time by an easy-to-implement algorithm.

1 Introduction

The longest common subsequence (LCS) problem is fundamental and well studied in computer science. The most common application of the LCS problem is measuring similarity between strings, which can be used in many applications such as the diff tool, the time series data analysis [12], and in bioinformatics.

One of the major disadvantages of LCS as a measure of similarity is that LCS cannot consider consecutively matching characters effectively. For example, for strings $X = \text{ATGG}$, $Y = \text{ATCGGC}$ and $Z = \text{ACCCTCGGGCG}$, ATGG is the LCS of $X$ and $Y$, which is also the LCS of $X$ and $Z$. Benson et al. [2] introduced the longest common subsequence in $k$ length substrings (LCS$_k$) problem, where the subsequence needs to be a concatenation of $k$ length substrings of given strings. For example, for strings $X = \text{ATCTATAT}$ and $Y = \text{TAATATCC}$, TAAT is an LCS$_2$ since $X[4 : : 5] = Y[1 : 2] = \text{TA}$ and $X[7 : 8] = Y[5 : 7] = \text{AT}$, and no longer one exists. They showed a quadratic time

*The final publication is available at Springer via http://dx.doi.org/10.1007/978-3-319-51963-0_28. However, it contains some crucial typos (see Appendix).
algorithm for it, and Deorowicz and Grabowski \cite{7} proposed several algorithms, such as a quadratic worst-case time algorithm for unbounded $k$ and a fast algorithm on average.

Pavetić et al. \cite{15} considered the longest common subsequence in at least $k$ length substrings (LCS$_{k^+}$) problem, where the subsequence needs to be a concatenation of at least $k$ length substrings of given strings. They argued that LCS$_{k^+}$ would be more appropriate than LCS$_k$ as a similarity measure of strings. For strings $X = \text{ATTGCTATCG}, Y = \text{ATGGTAATGG},$ and $Z = \text{AATCCCTCAA},$ LCS$_2(X,Y) = LCS_2(X,Z) = 4,$ where LCS$_2(A,B)$ denotes the length of an LCS$_2$ between $A$ and $B$. However, it seems that $X$ and $Y$ are more similar than $X$ and $Z$. Instead, if we consider LCS$_{2^+},$ we have $LCS_{2^+}(X,Y) = 6 > 4 = LCS_{2^+}(X,Z),$ that better fits our intuition. The notion of LCS$_{k^+}$ is applied to bioinformatics \cite{16}.

Pavetić et al. showed that LCS$_{k^+}$ can be computed in $O(m + n + r \log r + r \log n)$ time, where $m, n$ are lengths of the input strings and $r$ is the total number of matching $k$ length substring pairs between the input strings. Their algorithm is fast on average, but in the worst case, the running time is $O(mn \log(mn))$. Independently, Benson et al. \cite{2} proposed an $O(kmn)$ worst-case time algorithm for the LCS$_{k^+}$ problem.

In this paper, we first propose an algorithm to compute LCS$_{k^+}$ in $O(mn)$ worst-case time by a simple dynamic programming. Secondly, we introduce the longest common subsequence in at least $k$ length order-isomorphic substrings (op-LCS$_{k^+}$) problem. Order-isomorphism is a notion of equality of two numerical strings, intensively studied in the order-preserving matching problem\cite{1} \cite{13} \cite{14}. op-LCS$_{k^+}$ is a natural definition of similarity between numerical strings, and can be used in time series data analysis. The op-LCS$_{k^+}$ problem cannot be solved as simply as the LCS$_{k^+}$ problem due to the properties of the order-isomorphism. However, we will show that the op-LCS$_{k^+}$ problem can also be solved in $O(mn)$ worst-case time by an easy-to-implement algorithm, which is one of the main contributions of this paper. Finally, we report experimental results.

## 2 Preliminaries

We assume that all strings are over an alphabet $\Sigma$. The length of a string $X = (X[1], X[2], \ldots, X[n])$ is denoted by $|X| = n$. A substring of $X$ beginning at $i$ and ending at $j$ is denoted by $X[i : j] = (X[i], X[i + 1], \ldots, X[j - 1], X[j])$. We denote $X(i, +l) = X[i : i + l - 1]$ and $X(j, -l) = X[j - l + 1 : j]$. Thus $X(i, +l) = X(i + l - 1, -l)$. We write $X[: i]$ and $X[j :]$ to denote the prefix $X[1 : i]$ and the suffix $X[j : n]$ of $X$, respectively. Note that $X[: 0]$ is the empty string. The reverse of a string $X$ is denoted by $X^R$, and the operator $\cdot$ denotes the concatenation. We simply denote a string $X = (X[1], X[2], \ldots, X[n])$ as $X = X[1]X[2] \cdots X[n]$ when clear from the context.

We formally define the LCS$_{k^+}$ problem as follows.

**Definition 1** (LCS$_{k^+}$ problem \cite{2} \cite{15} \cite{2}). Given two strings $X$ and $Y$ of length $m$ and $n$, respectively, and an integer $k \geq 1$, we say that $Z$ is a common subsequence in at

---

1 Since the problem is motivated by the order-preserving matching problem, we abbreviate it to the op-LCS$_{k^+}$ problem.

2 The formal definition given by Pavetić et al. \cite{15} contains a minor error, i.e., they do not require that each chunk is identical, while Benson et al. \cite{2} and we do (confirmed by F. Pavetić, personal communication, October 2016).
least $k$ length substrings of $X$ and $Y$, if there exist $i_1, \cdots, i_t$ and $j_1, \cdots, j_t$ such that $X(i_s, +l_s) = Y(j_s, +l_s) = Z(p_s, +l_s)$ and $l_s \geq k$ for $1 \leq s \leq t$, and $i_s + l_s \leq i_{s+1}$, $j_s + l_s \leq j_{s+1}$ and $p_s + l_s$ for $1 \leq s < t$, $p_1 = 1$ and $|Z| = p_t + l_t - 1$. The longest common subsequence in at least $k$ length substrings (LCS$_{k^+}$) problem asks for the length of an LCS$_{k^+}$ of $X$ and $Y$.

Remark that the LCS$_{1^+}$ problem is equivalent to the standard LCS problem. Without loss of generality, we assume that $n \geq m$ through the paper.

**Example 1.** For strings $X = \text{acdbacbc}$ and $Y = \text{aacdabca}$, $Z = \text{acdbc}$ is the LCS$_{2^+}$ of $X$ and $Y$, since $X(1, +3) = Y(2, +3) = \text{acd} = Z(1, +3)$ and $X(7, +2) = Y(6, +2) = \text{bc} = Z(4, +2)$. Note that the standard LCS of $X$ and $Y$ is $\text{acdabc}$.

The main topic of this paper is to give an efficient algorithm for computing the longest common subsequence under order-isomorphism, defined below.

**Definition 2** (Order-isomorphism [13, 14]). Two strings $S$ and $T$ of the same length $l$ over an ordered alphabet are order-isomorphic if $S[i] \leq S[j] \iff T[i] \leq T[j]$ for any $1 \leq i, j \leq l$. We write $S \approx T$ if $S$ is order-isomorphic to $T$, and $S \not\approx T$ otherwise.

**Example 2.** For strings $S = (32, 40, 4, 16, 27)$, $T = (28, 32, 12, 20, 25)$ and $U = (33, 51, 10, 22, 42)$, we have $S \approx T$, $S \not\approx U$, and $T \not\approx U$.

**Definition 3** (op-LCS$_{k^+}$ problem). The op-LCS$_{k^+}$ problem is defined as the problem obtained from Definition 7 by replacing the matching relation $X(i_s, +l_s) = Y(j_s, +l_s) = Z(p_s, +l_s)$ with order-isomorphism $X(i_s, +l_s) \approx Y(j_s, +l_s) \approx Z(p_s, +l_s)$.

**Example 3.** For strings $X = (14, 84, 82, 31, 74, 68, 87, 11, 20, 32)$ and $Y = (21, 64, 2, 83, 73, 51, 5, 29, 7, 71)$, $Z = (1, 3, 2, 31, 74, 68, 87)$ is an op-LCS$_{3^+}$ of $X$ and $Y$ since $X(1, +3) \approx Y(3, +3) \approx Z(1, +3)$ and $X(4, +4) \approx Y(7, +4) \approx Z(4, +4)$.

The op-LCS$_{k^+}$ problem does not require that $(X(i_1, +l_1) \cdot X(i_2, +l_2) \cdot \cdots \cdot X(i_t, +l_t)) \approx (Y(j_1, +l_1) \cdot Y(j_2, +l_2) \cdot \cdots \cdot Y(j_t, +l_t))$. Therefore, the op-LCS$_{1^+}$ problem makes no sense. Note that the op-LCS$_{k^+}$ problem with this restriction is NP-hard already for $k = 1$ [3].

## 3 The LCS$_{k^+}$ Problem

In this section, we show that the LCS$_{k^+}$ problem can be solved in $O(mn)$ time by dynamic programming. We define $\text{Match}(i, j, l) = 1$ if $X(i, -l) \approx Y(j, -l)$, and 0 otherwise. Let $C[i, j]$ be the length of an LCS$_{k^+}$ of $X[: i]$ and $Y[: j]$, and $A_{i,j} = \{ C[i - l, j - l] + l \cdot \text{Match}(i, j, l) : k \leq l \leq \min\{i, j\} \}$. Our algorithm is based on the following lemma.

**Lemma 1** ([2]). For any $k \leq i \leq m$ and $k \leq j \leq n$,

$$C[i, j] = \max\{C[i, j-1], C[i-1, j] \cup A_{i,j}\},$$

(1)

and $C[i, j] = 0$ otherwise.
The naive dynamic programming algorithm based on Equation (1) takes \(O(m^2n)\) time, because for each \(i\) and \(j\), the naive algorithm for computing \(\max A_{i,j}\) takes \(O(m)\) time assuming \(n \geq m\). Therefore, we focus on how to compute \(\max A_{i,j}\) in constant time for each \(i\) and \(j\) in order to solve the problem in \(O(mn)\) time. It is clear that if \(\text{Match}(i, j, l_1) = 0\) then \(\text{Match}(i, j, l_2) = 0\) for all valid \(l_2 \geq l_1\), and \(C[i', j'] \geq C[i' - l', j' - l']\) for all valid \(i', j'\) and \(l' > 0\). Therefore, in order to compute \(\max A_{i,j}\), it suffices to compute \(\max_{k \leq l \leq L[i,j]} \{C[i, j - l] + l\}\), where \(L[i, j] = \max\{l : X(i, -l) = Y(j, -l)\}\).

We can compute \(L[i, j]\) for all \(0 \leq i \leq m\) and \(0 \leq j \leq n\) in \(O(mn)\) time by dynamic programming because the following equation clearly holds:

\[
L[i, j] = \begin{cases} 
L[i - 1, j - 1] + 1 & \text{if } i, j > 0 \text{ and } X[i] = Y[j] \\
0 & \text{otherwise.}
\end{cases} \tag{2}
\]

Next, we show how to compute \(\max_{k \leq l \leq L[i,j]} \{C[i, j - l] + l\}\) in constant time for each \(i\) and \(j\). Assume that the table \(L\) has already been computed. Let \(M[i, j] = \max_{k \leq l \leq L[i,j]} \{C[i, j - l] + l\}\) if \(L[i, j] \geq k\), and \(-1\) otherwise.

**Lemma 2.** For any \(0 \leq i \leq m\) and \(0 \leq j \leq n\), if \(L[i, j] > k\) then \(M[i, j] = \max\{M[i - 1, j - 1] + 1, C[i - k, j - k] + k\}\).

**Proof.** Let \(l = L[i, j]\). Since \(L[i, j] > k\), we have \(L[i - 1, j - 1] = l - 1 \geq k\), and \(M[i - 1, j - 1] = \max_{k \leq l \leq L[i,j]} \{C[i - 1 - l' - 1, j - l' - 1] + l'\} = \max_{k \leq l' \leq L[i,j]} \{C[i - l' - 1, j - l' - 1] + l'\} - 1\). Hence, \(M[i, j] = \max_{k \leq l' \leq L[i,j]} \{C[i - l' - 1, j - l' - 1] + l'\} = \max\{M[i - 1, j - 1] + 1, C[i - k, j - k] + k\}\). □

By Lemma 2 and the definition of \(M[i, j]\), we have

\[
M[i, j] = \begin{cases} 
\max\{M[i - 1, j - 1] + 1, C[i - k, j - k] + k\} & \text{if } L[i, j] > k \\
C[i - k, j - k] + k & \text{if } L[i, j] = k \\
-1 & \text{otherwise.}
\end{cases} \tag{3}
\]

Equation (3) shows that each \(M[i, j]\) can be computed in constant time if \(L[i, j]\), \(M[i - 1, j - 1]\), and \(C[i - k, j - k]\) have already been computed.

We can fill in tables \(C\), \(L\) and \(M\) of size \((m + 1) \times (n + 1)\) based on Equations (1), (2) and (3) in \(O(mn)\) time by dynamic programming. An example of computing LCS\(_{k^+}\) is shown in Fig. 3. We note that LCS\(_{k^+}\) itself (not only its length) can be extracted from the table \(C\) in \(O(m + n)\) time, by tracing back in the same way as the standard dynamic programming algorithm for the standard LCS problem. Our algorithm requires \(O(mn)\) space since we use three tables of size \((m + 1) \times (n + 1)\). Note that if we want to compute only the length of an LCS\(_{k^+}\), the space complexity can be easily reduced to \(O(km)\). Hence, we get the following theorem.

**Theorem 1.** The LCS\(_{k^+}\) problem can be solved in \(O(mn)\) time and \(O(km)\) space.

Figure 1: Examples of computing LCS₃⁺ and op-LCS₂⁺

4 The op-LCSₖ⁺ Problem

In this section, we show that the op-LCSₖ⁺ problem can be solved in \(O(mn)\) time as well as the LCSₖ⁺ problem. We redefine \(C[i, j]\) to be the length of an op-LCSₖ⁺ of \(X[: i]\) and \(Y[: j]\), and \(\text{Match}(i, j, l) = 1\) if \(X(i, -l) \approx Y(j, -l)\), and 0 otherwise. It is easy to prove that Equation (1) also holds with respect to the order-isomorphism. However, the op-LCSₖ⁺ problem cannot be solved as simply as the LCSₖ⁺ problem because Equations (2) and (3) do not hold with respect to the order-isomorphism. For two strings \(A, B\) of length \(l\) such that \(A \approx B\), and two characters \(a, b\) such that \(A \cdot a \neq B \cdot b\), the statement “\((A \cdot a)[i :) \neq (B \cdot b)[i :)\) for all \(1 \leq i \leq l + 1\)” is not always true. For example, for strings \(A = (32, 40, 4, 16, 27), B = (28, 32, 12, 20, 25), A’ = A \cdot (41)\) and \(B’ = B \cdot (26),\) we have \(A \approx B, A’ \neq B’,\) and \(A’[3 :) \approx B’[3 :]\). Moreover, for \(A'' = A \cdot (15)\) and \(B'' = B \cdot (22),\) we have \(A''[5 :) \approx B''[5 :]\). These examples show that Equations (2) and (3) do not hold with respect to the order-isomorphism. Therefore, we must find another way to compute \(\max_{k \leq l \leq t} \{C[i \cdot l’, j - l’] + l’\}\), where \(l = \max\{l’ : X(i, -l’) \approx Y(j, -l’)\}\) in constant time.

First, we consider how to find \(\max\{l : X(i, -l) \approx Y(j, -l)\}\) in constant time. We define the order-preserving longest common extension (op-LCE) query on strings \(S_1\) and \(S_2\) as follows.

**Definition 4 (op-LCE query).** Given a pair \((S_1, S_2)\) of strings, an op-LCE query is a pair of indices \(i_1\) and \(i_2\) of \(S_1\) and \(S_2\), respectively, which asks \(\text{opLCE}_{S_1, S_2}[i_1, i_2] = \max\{l : S_1[i_1, +l] \approx S_2[i_2, +l]\}\).

Since \(\max\{l : X(i, -l) \approx Y(j, -l)\} = \text{opLCE}_{X, Y}[m - i + 1, n - j + 1]\), we can find \(\max\{l : X(i, -l) \approx Y(j, -l)\}\) by using op-LCE queries on \(X^R\) and \(Y^R\). Therefore, we focus on how to answer op-LCE queries on \(S_1\) and \(S_2\) in constant time with at most \(O(|S_1| + |S_2|)\) time preprocessing. Hereafter we write \(\text{opLCE}[i_1, i_2]\) for \(\text{opLCE}_{S_1, S_2}[i_1, i_2]\) fixing two strings \(S_1\) and \(S_2\).

If \(S_1\) and \(S_2\) are strings over a polynomially-bounded integer alphabet \(\{1, \ldots, (|S_1| + |S_2|)^c\}\) for an integer constant \(c\), op-LCE queries can be answered in \(O(1)\) time and \(O(|S_1| + |S_2|)\) space with \(O((|S_1| + |S_2|) \log^2 \log(|S_1| + |S_2|) / \log \log \log (|S_1| + |S_2|))\) time preprocessing, by using the incomplete generalized op-suffix-tree of \(S_1\) and \(S_2\) and
finding the lowest common ancestor (LCA) [1] in the op-suffix-tree. The proof is similar to that for LCE queries in the standard setting [10].

However, implementing the incomplete generalized op-suffix-tree is quite difficult. Therefore, we introduce another much simpler method to answer op-LCE queries in \( O(1) \) time with \( O(|S_1| |S_2|) \) time preprocessing. In a preprocessing step, our algorithm fills in the table \( \text{opLCE}[i_1, i_2] \) for all \( 1 \leq i_1 \leq |S_1| \) and \( 1 \leq i_2 \leq |S_2| \) in \( O(|S_1| |S_2|) \) time. Then, we can answer op-LCE queries in constant time.

In the preprocessing step, we use the Z-algorithm [10, 11] that calculates the following table efficiently.

**Definition 5** (Z-table). The Z-table \( Z_S \) of a string \( S \) is defined by \( Z_S[i] = \max\{l : S(i, +l) \approx S(i, +l)\} \) for each \( 1 \leq i \leq |S| \).

By definition, we have

\[
\text{opLCE}[i_1, i_2] = \min\{Z(S_{i_1, S_{i_2}})[i_1 : i_2] \mid |S_1| - i_1 + 1, |S_1| - i_2 + 1\}. \tag{4}
\]

If we use the Z-algorithm and Equation (4) naively, it takes \( O((|S_1| + |S_2|)^2 \log(|S_1| + |S_2|)) \) time to compute \( \text{opLCE}[i_1, i_2] \) for all \( 1 \leq i_1 \leq |S_1| \) and \( 1 \leq i_2 \leq |S_2| \), because the Z-algorithm requires \( O(|S| \log |S|) \) time to compute \( Z_S \) for a string \( S \). We extend the Z-algorithm to compute \( Z_S[i] \) for all \( 1 \leq i \leq |S| \) totally in \( O(|S|^2) \) time.

In order to verify the order-isomorphism in constant time with preprocessing, Hasan et al. [11] used tables called \( \text{Prev}_S \) and \( \text{Next}_S \). For a string \( S \) where all the characters are distinct, \( \text{Prev}_S \) and \( \text{Next}_S \) are defined as

\[
\text{Prev}_S[i] = j \text{ if there exists } j = \arg\max_{1 \leq k < i} \{S[k] : S[k] < S[i]\}, \text{ and } -\infty \text{ otherwise}
\]

\[
\text{Next}_S[i] = j \text{ if there exists } j = \arg\min_{1 \leq k < i} \{S[k] : S[k] > S[i]\}, \text{ and } \infty \text{ otherwise}
\]

for all \( 1 \leq i \leq |S| \). Their algorithm requires \( O(|S| \log |S|) \) time to compute the tables \( \text{Prev}_S \) and \( \text{Next}_S \), and all operations except computing the tables take only \( O(|S|) \) time. Therefore, if we can compute tables \( \text{Prev}_S[i] \) and \( \text{Next}_S[i] \) for each \( 1 \leq i \leq |S| \) in \( O(|S|) \) time with \( O(|S| \log |S|) \) time preprocessing, \( Z_S[i] \) for all \( 1 \leq i \leq |S| \) can be computed in \( O(|S|^2) \) time. We also assume that all the characters in \( S \) are distinct.\(^5\)

In order to compute the tables \( \text{Prev}_S[i] \) and \( \text{Next}_S[i] \), we modify a sort-based algorithm presented in Lemma 1 in [14] instead of the algorithm in [11] that uses a balanced binary search tree. First, for computing \( \text{Prev}_S \) (resp. \( \text{Next}_S \)), we stably sort positions of \( S \) with respect to their elements in ascending (resp. descending) order. We can compute \( \text{Prev}_S[i] \) and \( \text{Next}_S[i] \) for each \( 1 \leq i \leq |S| \) in \( O(|S|) \) time by using the sorted tables and the stack-based algorithm presented in [14], ignoring all elements of the sorted tables less than \( i \).

Algorithm 1 shows the pseudocode of the op-LCE algorithm based on the Z-algorithm. The \text{push}(x) \) operation inserts \( x \) on the top of the stack, \text{top}() \) returns the top element

\(^5\) Hasan et al. [11] assume that characters in a string are distinct. If the assumption is false, use Lemma 4 in [4] in order to verify the order-isomorphism, that is, modify line 10 of Algorithm 4 in [11] and line 7 and line 12 in Algorithm 4. Note that \( \text{Prev} \) and \( \text{Next} \) are denoted as \( \text{LMax} \) and \( \text{LMin} \) in [4], respectively, with slight differences.

18 Do the same operations described in line 3-17 of Algorithm 4 in [11];
19 return $Z$;

20 Function preprocess-opLCE($S_1, S_2$)
21 Let $opLCE$ be a table of size $|S_1| \times |S_2|$; $S \leftarrow S_1 \cdot S_2$;
22 Let $S'$ and $S''$ be stably sorted positions of $S$ with respect to their elements in
23 ascending and descending order, respectively;
24 for $i_1 \leftarrow 1$ to $|S_1|$ do
25   $Z \leftarrow$ Z-function($S, i_1, S', S''$);
26 for $i_2 \leftarrow 1$ to $|S_2|$ do
27   $opLCE[i_1, i_2] \leftarrow \min \{Z[|S_1| - i_1 + i_2 + 1], |S_1| - i_1 + 1\}$;
28 return $opLCE$;
Algorithm 2: The algorithm for the $\text{op-LCS}_{k^+}$ problem

**Input:** A string $X$ of length $m$, a string $Y$ of length $n$, and an integer $k$

**Output:** The length of an $\text{op-LCS}_{k^+}$ between $X$ and $Y$

1. Let $C$ be a table of size $(m + 1) \times (n + 1)$ initialized by 0;
2. Let $R_i$ for $-n + k \leq i \leq m - k$ be semi-dynamic RMQ data structures;
3. $\text{opLCE} \leftarrow \text{preprocess-opLCE}(X^R, Y^R)$;
4. for $i \leftarrow 0$ to $m - k$ do
   5. if $i < k$ then $n' \leftarrow n - k$;
   6. else $n' \leftarrow k - 1$;
   7. for $j \leftarrow 0$ to $n'$ do $R_{i-j}\text{.prepend}(C[i, j] - \min\{i, j\})$;
8. for $i \leftarrow k$ to $m$ do
   9. for $j \leftarrow k$ to $n$ do
   10. $l \leftarrow \text{opLCE}[m - i + 1, n - j + 1]$;
   11. if $l \geq k$ then $M \leftarrow R_{i-j}\text{.rmq}(k, l) + \min\{i, j\}$;
   12. else $M \leftarrow 0$;
   13. $C[i, j] \leftarrow \max\{C[i, j - 1], C[i - 1, j], M\}$;
   14. $R_{i-j}\text{.prepend}(C[i, j] - \min\{i, j\})$;
15. return $C[m, n]$;

in the stack, and $\text{pop}()$ removes it. Algorithm 1 takes $O(|S_1||S_2|)$ time as discussed above. The total space complexity is $O(|S_1||S_2|)$ because the Z-algorithm requires linear space \[\text{III}\], and the table $\text{opLCE}$ needs $O(|S_1||S_2|)$ space. Hence, we have the following lemma.

**Lemma 3.** $\text{op-LCE}$ queries on $S_1$ and $S_2$ can be answered in $O(1)$ time and $O(|S_1||S_2|)$ space with $O(|S_1||S_2|)$ time preprocessing.

Let $\text{opLCE}(i, j)$ be the answer to the $\text{op-LCE}$ query on $X^R$ and $Y^R$ with respect to the index pair $(i, j)$. We consider how to find the maximum value of $C[i - l, j - l] + l$ for $k \leq l \leq \text{opLCE}(m - i + 1, n - j + 1)$ in constant time. We use a semi-dynamic range maximum query (RMQ) data structure that maintains a table $A$ and supports the following two operations:

- $\text{prepend}(x)$: add $x$ to the beginning of $A$ in $O(1)$ amortized time.
- $\text{rmq}(i_1, i_2)$: return the maximum value of $A[i_1 : i_2]$ in $O(1)$ time.

The details of the semi-dynamic RMQ data structure will be given in Section 5.

By using the semi-dynamic RMQ data structures and the following obvious lemma, we can find $\max_{k \leq l \leq \text{opLCE}(m - i + 1, n - j + 1)}\{C[i - l, j - l] + l\}$ for all $1 \leq i \leq m$ and $1 \leq j \leq n$ in totally $O(mn)$ time.

**Lemma 4.** We may assume that $i \geq j$ without loss of generality. Let $A[l] = C[i - l, j - l] + l$ and $A'[l] = C[i - l, j - l] - j + l$ for each $1 \leq l \leq j$. For any $1 \leq i_1, i_2 \leq |A|$, we have

$$\max_{1 \leq l \leq i_2} A[l] = (\max_{1 \leq l \leq i_2} A'[l]) + j$$

and

$$\argmax_{1 \leq l \leq i_2} A[l] = \argmax_{1 \leq l \leq i_2} A'[l].$$
Figure 2: An example of searching for the RMQ by using a 2d-Min-Heap and the ±1RMQ algorithm [1]. The tree shows the 2d-Min-Heap of $X = (4, 6, 5, 7, 3, 4, 5, 3)$ represented by arrays $E$ and $D$. The gray node 8 in the tree and gray numbers in the table are added when the last character $X[8] = 3$ is processed. The boxes with the dashed lines show the answers of RMQs $\text{rmq}(2, 4)$ and $\text{rmq}(5, 7)$.

Algorithm 3 shows our algorithm to compute op-LCS$_{k^+}$. An example of computing op-LCS$_{2^+}$ is shown in Fig. 1(b). As discussed above, the algorithm runs in $O(mn)$ time. Each semi-dynamic RMQ data structure requires linear space and a total of $O(mn)$ elements are maintained by the semi-dynamic RMQ data structures. Therefore, the total space of semi-dynamic RMQ data structures is $O(mn)$. Consequently, the total space complexity is $O(mn)$. Hence, we have the following theorem.

**Theorem 2.** The op-LCS$_{k^+}$ problem can be solved in $O(mn)$ time and space.

5 The Semi-dynamic Range Minimum/Maximum Query

In this section we will describe the algorithm that solves the semi-dynamic RMQ problem with $O(1)$ query time and amortized $O(1)$ prepend time. To simplify the algorithm, we consider the prepend operation as appending a character into the end of array. In order to solve this problem, Fischer [8] proposed an algorithm that uses a 2d-Min-Heap [9] and dynamic LCAs [5]. However, the algorithm for dynamic LCAs is very complex to implement. Therefore, we propose a simple semi-dynamic RMQ algorithm that can be implemented easily if the number of characters to be appended is known beforehand. This algorithm uses a 2d-Min-Heap and the ±1RMQ algorithm proposed by Bender and Farach-Colton [1].

Let $X$ be a string of length $n$ and let $X[0] = -\infty$. The 2d-Min-Heap $H$ of $X$ is an ordered tree of $n + 1$ nodes $\{0, 1, \ldots, n\}$, where 0 is the root node, and the parent node of node $i > 0$ is $\max\{j < i : X[j] < X[i]\}$. Moreover, the order of the children is chosen so that they increase from left to right (see Fig. 2 for instance). Note that the vertices are inevitably aligned in preorder. Actually, the tree $H$ is represented by arrays $E$ and $D$ that store the sequences of nodes and their depths visited in an Euler tour of $H$, respectively. In addition, let $Y$ be an array defined as $Y[i] = \min\{j : E[j] = i\}$ for each $1 \leq i \leq n$.

For two positions $1 \leq i_1 \leq i_2 \leq n$ in $X$, $\text{rmq}(i_1, i_2)$ can be calculated by finding $\text{lca}(i_1, i_2)$, the LCA of the nodes $i_1$ and $i_2$ in $H$. If $\text{lca}(i_1, i_2) = i_1$, then $\text{rmq}(i_1, i_2) = i_1$. 

9
Otherwise, \( \text{rmq}(i_1, i_2) = i_3 \) such that \( i_3 \) is a child of \( \text{lca}(i_1, i_2) \) and an ancestor of \( i_2 \). The \( \text{lca}(i_1, i_2) \) can be computed by performing the \( \pm 1 \)RMQ query \( \text{rmq}(Y[i_1], Y[i_2]) \) on \( D \), because \( D[j + 1] - D[j] = \pm 1 \) for every \( j \). It is known that \( \pm 1 \)RMQs can be answered in \( O(1) \) time with \( O(n) \) time preprocessing [1]. Therefore, we can calculate \( \text{rmq}(i_1, i_2) \) as follows,

\[
\text{rmq}(i_1, i_2) = \begin{cases} 
E[\text{rmq}(Y[i_1], Y[i_2])] & \text{if } E[\text{rmq}(Y[i_1], Y[i_2])] = i_1 \\
E[\text{rmq}(Y[i_1], Y[i_2])] + 1 & \text{otherwise}.
\end{cases}
\]

Fig. 2 shows an example of calculating the RMQ. From the property of a 2d-Min-Heap, arrays \( E \) and \( D \) are always extended to the end when a new character is appended. Moreover, the \( \pm 1 \)RMQ algorithm can be performed semi-dynamically if the size of sequences is known beforehand, or by increasing the arrays size exponentially. Therefore, this algorithm can be performed online and can solve the semi-dynamic RMQ problem, as we intended.

6 Experimental Results

In this section, we present experimental results. We compare the running time of the proposed algorithm in Section 3 to the existing algorithms [2, 15]. Furthermore, we show the running time of Algorithm 2. We used a machine running Ubuntu 14.04 with Core i7 4820K and 64GB RAM. We implemented all algorithms in C++ and compiled with gcc 4.8.4 with -O2 optimization. We used an implementation of the algorithm proposed by Pavetić et al., available at [github.com/fpavetic/lcskpp](https://github.com/fpavetic/lcskpp). We denote the algorithm proposed by Pavetić et al. [15] and the algorithm proposed by Benson et al. [2] as PŽS and BLMNS, respectively.

We tested the proposed algorithm in Section 3, PŽS, and BLMNS in the following three conditions: (1) random strings over an alphabet of size \( |\Sigma| = 4 \) with \( n = m = 1000, 2000, \cdots, 10000 \) and \( k = 1, 2, 3, 4 \) (2) random strings over alphabets of size \( |\Sigma| = 1, 2, 4, 8 \) with \( n = m = 1000, 2000, \cdots, 10000 \) and \( k = 3 \) (3) DNA sequences that are available at [www.ncbi.nlm.nih.gov/nucore/346214858](https://www.ncbi.nlm.nih.gov/nucore/346214858) and [www.ncbi.nlm.nih.gov/nucore/U38845.1](https://www.ncbi.nlm.nih.gov/nucore/U38845.1) with \( k = 1, 2, 3, 4, 5 \). The experimental results under the conditions (1), (2) and (3) are shown in Figs. 3(a), 3(b), and 3(c), respectively.

The proposed algorithm in Section 3 runs faster than PŽS for small \( k \) or small alphabets. This is due to that PŽS strongly depends on the total number of matching \( k \) length substring pairs between input strings, and for small \( k \) or small alphabets there are many matching pairs. In general BLMNS runs faster than ours. The proposed algorithm runs a little faster for small \( k \) or small alphabets, except \( |\Sigma| = 1 \). We think that this is because for small \( k \) or small alphabets the probability that \( L[i, j] \geq k \) is high, and this implies that we need more operations to compute \( M[i, j] \) by definition. In Fig. 3(b) it is observed that the proposed algorithm with \( |\Sigma| = 1 \) runs faster than with \( |\Sigma| = 2 \). Since \( |\Sigma| = 1 \) implies that \( X = Y \) if \( X \) and \( Y \) have the same length, \( L[i, j] > k \) almost always holds, which leads to reduce branch mispredictions and speed up execution.

We show the running time of Algorithm 2 in Fig. 3(d). We tested Algorithm 2 on random strings over \( \Sigma = \{1, 2, \cdots, 100\} \) with \( n = m = 1000, 2000, \cdots, 10000 \) and \( k = 2, 3, 4, 5 \). It is observed that the algorithm runs faster as the parameter \( k \) is smaller.
We suppose that the hidden constant of the RMQ data structure described in Section 5 is large. Therefore, the running time of Algorithm 2 depends on the number of times the \texttt{rmq} operation is called, and for small \(k\) the number of them increases since the probability that \(l \geq k\) is high.

7 Conclusion

We showed that both the LCS\(_{k^+}\) problem and the op-LCS\(_{k^+}\) problem can be solved in \(O(mn)\) time. Our result on the LCS\(_{k^+}\) problem gives a better worst-case running time than previous algorithms [2, 15], while the experimental results showed that the previous algorithms run faster than ours on average. Although the op-LCS\(_{k^+}\) problem looks much more challenging than the LCS\(_{k^+}\), since the former cannot be solved by a simple dynamic programming due to the properties of order-isomorphisms, the proposed algorithm achieves the same time complexity as the one for the LCS\(_{k^+}\).
