ABSTRACT

Gray Wolfe Optimization (GWO) is one of the meta-heuristic method and it is a popular technique in Many engineering and economic applications. GWO and Least Square Estimation (LSE) are used to optimize the antecedents and consequents parameters of interval type-2 ANFIS respectively. We are checking the new learning algorithm by using the interval type-2 ANFIS in prediction of Mackey-Glass time series and the results were very encouraging compared to other algorithms.

I- Introduction

Zadeh in his paper [1] was present the idea of fuzzy sets, where it was the begin new covenant of knowledge, because the concept of fuzzy logic gave the computer ability to make a decision differently than normal logic. The dealing with relation becomes flexible where terms “tall”, “big”, “hot”,…etc. In 1975 [2], Zadeh expanded his concept of fuzzy logic to which gave a wider area of resolution than the previous type as it gives several opinions instead of one opinion the type-II fuzzy logic.

The Artificial Neural Networks (ANN) are systems has adjusted the processing of information [3, 4], ANNs with FLSs are good hybrid systems which are used the features of two techniques ANNs and FLSs, one of this kinds is Adaptive Neuro Fuzzy Inference System (ANFIS) which was suggested by Jang 1993 [5].

II- Architectural of ANFIS

The architectural of ANFIS is almost similar to the structure of FLS because of both are Receive the crisp values as inputs and then converts to fuzzy value. Then a series of operations are carried out on the fuzzy values, in order to finally remove the fuzziness from them for crisp values. Since this system is composed between two intelligence systems then we will achieve a system in quality or we can say that we have a fuzzy thinking and Network computation.

As in the FLS then ANFIS in general consists of two parts, the antecedents is the first part and the consequents part is the second part. The structure of ANFIS of five layers which is shown in the fig.(1), where the fuzzification procedure is in the first layer, in the second layer the implementation of fuzzy and the rule by the fuzzy process, the normalized of the membership function is executed in the third layer, in the fourth layer the process of finding values of consequents part and the fifth layer is used to find the finally output of ANFIS [5].

\[
O_{i}^{1} = \mu_{A_{i}}(x) \quad \text{For} \quad i = 1,2
\]  

\[
O_{i}^{2} = w_{i} = \mu_{A_{i}}(x) \times \mu_{A_{i}}(x), \quad i = 1,2
\]

Where \( A_{i} \) is the fuzzy set of inputs, \( \mu_{A_{i}}(x) \) is the membership function of \( x \) in \( A_{i} \). \( \bar{f}_{i} \) is the output of layer 3, and \( (p_{i}, q_{i}, r_{i}) \) is the consequent parameters of this node \( i \).

\[
\bar{w}_{i} = w_{i}^{1} + w_{i}^{2}, \quad i = 1,2
\]

\[
O_{i}^{1} = \bar{w}_{i} f_{i} = \bar{w}_{i}(p_{i}x_{1} + q_{i}x_{2} + r_{i})
\]

\[
O_{i}^{2} = \text{overalloutput} = \sum_{i} \bar{w}_{i} f_{i} = \frac{\sum_{i} w_{i} f_{i}}{w_{i}}
\]

Finally, the values of the consequent parameters can we find by use a least square algorithm, as follow:
The number of input and output patterns is usually $q$, which is used by training greater than the number of consequent parameters $n(1 + m)$. This means that finding the solution of (eq.8) accurately may not be possible, so we use guessing using the method a least-square estimate of $S, S^*$, that minimises the squared error $\|AS - y\|^2$. It is done by using the pseudoinverse technique [6],

$$\hat{\theta} = (A^T A)^{-1} A^T y \quad (9)$$

where $A^T$ is the transpose of $A$, and $(A^T A)^{-1} A^T$ is the pseudoinverse of $A$ if $(A^T A)$ is non-singular. In this case, the parameters of the rule consequent are estimated. Then, the forward pass of this epoch is complete and we can calculate the error vector as follow

$$e = y - \hat{y} \quad (10)$$

In the backward pass, the error signals are propagated back and the rule antecedent parameters are updated by use gradient descent method: Calculate partial derivatives per chain rule

$$\frac{\partial e}{\partial A} = \frac{1}{2} e^2 = \frac{1}{2} (y - \hat{y})^2 \quad (11)$$

and since we want to update the parameters of membership functions, may be triangular or may be trapezoidal or other, then if we suppose that the type of membership is trapezoidal, therefore we have four parameters $a, b, c, and d$.

$$\Delta \theta = \theta + \frac{\partial e}{\partial \theta} \quad (12)$$

then,

$$\theta = \theta + \Delta \theta \quad (13)$$

as similar, we can update the other parameters $b, c, and d$. The proposed training is also a hybrid of the two methods, the first is the least-squares method or the forward pass has not changed is the same as in the original of the ANFIS training that means that values of linear equations will be updated in the original method, but the change is in the backward pass, where update to the values of membership functions variables will be updated based on the Gray Wolfe Optimization (GWO) method instead of gradient descent in the beginning give initial population and initial values of these variables and so on in accordance with GWO steps are updating those values that reach specific resolution or a specific error is allowed.

**IV- INTERVAL TYPE-2 ADAPTIVE NEURO-FUZZY INFERENCE SYSTEMS (IT2ANFIS)**

IT2ANFIS with each of upper and lower MFs to be as two separate ANFISs, i.e. there are two ANFISs where the overall outputs of each of them are $y$ upper (denotes $y_u$) and $y$ lower (denotes $y_l$) and the overall output of IT2 ANFIS is the average of these two outputs. The system used in this study has four inputs $x_1$, $x_2$, $x_3$, and $x_4$ each in two fuzzy sets and one output $y$. 

---

**Figure (1) ANFIS architecture for a two-input, two-rule of first-order Sugeno model**
As previously mentioned that an ANFIS is multi-layered, ANFIS architecture consists of five layers, Fig. 1, the nodes in the first and fourth layers are adaptive, while the nodes in the other layers are fixed [3]. Note that a symbol $O_{il}$ will be used to refer to the $ith$ node output in layer $l$. These layers can be briefly described, as used in this study and for each ANFIS in this model, as follows [7]:

**Layer 1:** The adapted of each node in this layer being by the following function

$$O_{0il} = \mu_{A_i}(x_l)$$

or

$$O_{0il} = \mu_{B_{i-1}}(x_{l+1})$$

or

$$O_{0il} = \mu_{C_{i-1}}(x_{l+2})$$

or

$$O_{0il} = \mu_{D_{i-1}}(x_{l+3})$$

In other words, each $O_{0il}$ is a membership grade of a fuzzy set $A$ where $A = A_1, A_2, B_1, B_2, C_1, C_2, D_1$ or $D_2$. Here an IT2 Gaussian MFs with uncertain standard deviation and fixed mean parameters of the layer 1 named premise.

**Layer 2:** Each node in this layer is labeled $[l]$, whose output is obtained using $\cap$-norm operators (product or min), that perform AND on all incoming signals, i.e., if the firing strength of every rule.

$$O_{1il} = w_i = \text{The firing strength of each rule } i$$

for all $i = 1, 2, \ldots, 16$

**Layer 3:** Each $ith$ node in this layer, is labeled $N_i$, whose output is calculated by the following form:

$$O_{3il} = \frac{w_i}{\sum_{i=1}^{16} w_i}$$

where $w_i$ is the $ith$ rule's firing strength. Therefore the outputs here called normalized firing strengths.

**Layer 4:** Every $ith$ node in this layer, is an adaptive node, as previously mentioned, with a node function:

$$O_{4il} = \sum_{i=1}^{16} w_{il} f_i = \sum_{i=1}^{16} \frac{w_{il} f_i}{\sum_{i=1}^{16} w_i}$$

where $f_i$ is the output of layer 3 (a normalized firing strength) and $c_{1i}, c_{2i}, c_{3i}, c_{4i}$ and $c_{0i}$ are the parameters whose called consequent.

**Layer 5:** In this layer there is a single node denoted by $\Sigma$, which output is the overall output $y$ computed as follows:

$$y = O_{5il} = \sum_{i=1}^{16} \frac{w_{il} f_i}{\sum_{i=1}^{16} w_i}$$

Since we are working with two ANFISs, hence there are two overall outputs, $y_u$ and $y_l$. Therefor the overall output of the IT2 ANFIS is computing as follows:

$$y = \frac{y_u + y_l}{2}$$

**V. The hybrid learning algorithm**

As previously mentioned, an ANFIS is supervised system with a hybrid learning algorithm. In this study, a hybrid learning of Least-Squared Estimator (LSE), [7] and Grey Wolf Optimizer (GWO) used to optimize the consequent and antecedent parameters, respectively. Briefly, a GWO method can be described in these following steps [8]:

1. Calculate the coefficient vectors $\hat{A}$ and $\hat{C}$ as follows:
   $$\hat{A} = 2\hat{a} \cdot \hat{r}_1 - \hat{a}$$
   $$\hat{C} = 2 \cdot \hat{r}_2$$

2. $\hat{a}$ is linearly decreased function from 2 to 0 can be taken as:
   $$\hat{a} = 2 \left( 1 - \frac{\text{epoch}}{\text{max number of iterations}} \right)$$

3. for all epoch = 1, 2, … , max number of iteration and random vectors $\hat{r}_1$ and $\hat{r}_2$ are their values are in the interval [0,1].

4. Then calculate:
   $$\bar{D}_a = |\hat{C}_1 \cdot \bar{m}_a - \bar{m}|$$
   $$\bar{D}_b = |\hat{C}_2 \cdot \bar{m}_b - \bar{m}|$$
   $$\bar{D}_c = |\hat{C}_3 \cdot \bar{m}_c - \bar{m}|$$
   $$\bar{D}_d = |\hat{C}_4 \cdot \bar{m}_d - \bar{m}|$$
   $$\bar{m}_1 = \bar{m}_a - \bar{A}_1 \cdot \bar{D}_a$$
   $$\bar{m}_2 = \bar{m}_b - \bar{A}_2 \cdot \bar{D}_b$$
   $$\bar{m}_3 = \bar{m}_c - \bar{A}_3 \cdot \bar{D}_c$$
   $$\bar{m}_4 = \bar{m}_d - \bar{A}_4 \cdot \bar{D}_d$$
   $$\bar{m} = \frac{\bar{m}_1 + \bar{m}_2 + \bar{m}_3 + \bar{m}_4}{4}$$

5. $\bar{m}$, $\bar{m}_a$, $\bar{m}_b$, $\bar{m}_c$, and $\bar{m}_d$ will described in the pseudo code of LSE-GWO.

The hybrid LSE-GWO pseudo code of its algorithm is as follows:

**Initialize population of (GWO) $m_i$ (which refer to the means) ($i = 1, 2, \ldots, n$)

**Initialize the rest of T2 Gaussian MF parameters ($\sigma_1$ and $\sigma_2$)

**Initialize $a$, $A$, and $C$

**Compute the IT2 ANFIS consequent parameters using LSE

**Compute the efficiency, RMSE, of every search agent

$m_a$=the first optimum search agent

$m_b$=the second optimum search agent

$m_c$=the third optimum search agent

for each epoch (epoch=1:maximum no. of epochs)

for every search agent

Update the position of the current search agent by eq.(34)

for end

end for

**Compute the consequent of all search agents by LSE

Update $m_a$, $m_b$, and $m_c$

end for

Pseudo code of the LSE-GWO algorithm

Next, the experimental analysis and adoption (or simulation) results discussion presented. we used the root mean square error (RMSE) to be the implement criterion for all experiments which calculates as (Eyoh et al., 2017; Ren et al., 2011)

$$RMSE = \sqrt{\frac{1}{N} \sum_{i=1}^{N} (y^a - y)^2}$$

where $N$ is the training (or checking) data points number, $y$ is the model output and $y^a$ is the desired output.

**VI. EXPERIMENTS AND RESULTS**

To evaluate the IT2 ANFIS performance, we implemented it for a MG time series that is a well-known dataset which defined by a non-linear differential delay equation as following [9]:

$$\frac{dx(t)}{dt} = \frac{a x(t-\tau)}{1 + x^2(t-\tau)} - b x(t)$$

(34)
s.t. $a$, $b$ and $n$ are constant, $t$ refers to the current time and $\tau$ is a time delay parameter non-negative constant used to produce the chaotic behavior in the data [10], which it turns to the chaotic when $\tau > 17$ [11].

To allow comparison with other works, the initial condition used in the method was $x(0) = 1.2$, the time step was $0.1$, $a = 0.2$, $b = 0.1$, $n = 10$ and $\tau = 17$. Similar to [7] we extracted 1000 input-output data pairs from the chaotic MG time series $x(t)$ of the following format:

$$\{x(t-18), x(t-12), x(t-6), x(t); x(t+6)\}$$

where $x(t+6)$ is the output obtained from the input vector $\{x(t-18), x(t-12), x(t-6), x(t)\}$, where $t = 118$ to $1117$. The dataset divided into two sets, the first 500 pairs used to be the training dataset for the IT2 ANFIS and the remaining 500 pairs of the data used to be the checking dataset for validating the identified IT2 ANFIS.

After iterating these two models many times, we had $RMSE_{err} = 0.001683$ and $RMSE_{chk} = 0.001465$ from model I. While the results obtained from model II were $RMSE_{err} = 0.000719$ and $RMSE_{chk} = 0.000551$ as shown in Table I. The results obtained from applying different approaches to Mackey-Glass prediction are listed in Table II.

### Table II: The results comparison for prediction MG time series

| Models                          | RMSE |
|---------------------------------|------|
| ANFIS Ensemble with IT2FLS [12] | 0.04933 |
| IT2FLS [13]                     | 0.0335 |
| SA-IT2FLS [9]                   | 0.0089 |
| IT2FLS-TSK [11]                 | 0.0079 |
| ANFIS [7]                       | 0.0015 |
| The proposed method             | 0.001465 |

### VII - CONCLUSION

The new hybrid LSE-GWO learning algorithm is used to optimize the IT2 ANFIS by searching for the best parameters of antecedents and consequents by using two models. The MG time series has been predicted by these proposed methods. Both type-1 and interval type-2 ANFIS, in their ability, have been compared to handle uncertainty and a good results had been obtained comparing with the other hybrid algorithms. In future work, we will use a new algorithm to optimize the parameters of the Interval type-2 ANFIS.
