RESPONSE TO COMMENT ON LONTCHI-YIMAGOU ET AL.

An Atypical Form of Diabetes Among Individuals With Low BMI. Diabetes Care 2022;45:1428–1437

Diabetes Care 2022;45:e159–e160 | https://doi.org/10.2337/dci22-0031

We thank Unnikrishnan et al. (1) for their thoughtful comments on our article (2). We agree with the need for further research into the globally prevalent condition we termed “low-BMI diabetes” (LD) and that the previous nomenclature “malnutrition-related diabetes” requires more evidence. We propose, nonetheless, on the basis of extensive phenotyping, that LD represents a distinct form of diabetes with implications for prevention and treatment (2).

Lean individuals with diabetes have been reported in many low- and middle-income countries (LMICs) (2). Our goal in performing these studies at Christian Medical College, Vellore, India, was not to address “Indian” presentations of diabetes (which have been extensively studied by authors of the comment letter) but to use state-of-the-art techniques generally unavailable in LMICs: stepped insulin pancreatic clamps, C-peptide deconvolution, and sophisticated anthropometric measures. Glucose toxicity was corrected, and patients with pancreatic calculi, type 1 diabetes, and monogenic diabetes were excluded (2).

Most type 2 diabetes (T2D) patients have some degree of impaired β-cell function, the magnitude of which differs between patients and over time. Our intensive measures of insulin secretion revealed more severe defects in LD patients than in T2D patients. Might some patients with severe insulin-deficient diabetes, as described by Anjana et al., also be considered LD patients, given their apparently wide range of BMI (3)? It would be intriguing to use C-peptide deconvolution techniques to study individuals with severe insulin-deficient diabetes along that BMI spectrum (while correcting confounding glucose toxicity) to determine whether there is a gradient of insulin secretory defects.

LD is anthropometrically distinct from the classic description of the so-called thin-fat Indian developed extensively by Yajnik (4), because our LD subjects have a BMI well below the South Asian inflection point of ~22 kg/m² and lack visceral adiposity. It should be emphasized that the LD phenotype revealed in our article, characterized by low BMI with low body fat content, was unconfounded by later life overnutrition and deserves consideration as a distinct phenotype.

Notably, only time course studies can prospectively determine the pathophysiological relationship between nutrition and diabetes. Such determinations are challenging, since malnutrition often occurs in the setting of other stressors. While much research has established the effect of fetal malnutrition on risk of T2D (4,5), some research in animals and humans suggests that continued undernutrition in childhood and adulthood contributes to the distinct LD phenotype (6).

Importantly, we believe that recognizing LD as a distinct entity is essential from a therapeutic perspective. Weight loss would be inappropriate, and metformin would fail to address the reduced insulin secretion. Moreover, agents that precipitate hypoglycemia are dangerous in the face of food insecurity, and insulin use is problematic in many LMICs.

Further research to understand the pathophysiology of LD would be important but challenging. Many genes that limit β-cell development in undernutrition can also hasten β-cell exhaustion in obesity, raising the question of whether biomarkers or putative genes could distinguish this condition. Meanwhile, developing appropriate treatment strategies is critical given the high estimated global prevalence of LD and the pending food crisis.

Acknowledgments. The authors are thankful for very helpful discussions with Professors C.S. Yajnik (Diabetes Unit, King Edward Memorial Hospital, Pune, India), Allan Vaag (Department of Endocrinology and Metabolism, University of Copenhagen, Denmark), Moffat Nyirenda (Hygiene and Tropical Medicine and Malawi Epidemiology and Intervention Research Unit), and Suzanne Filteau (Department of Population Health, London School of Hygiene and Tropical Medicine, London, U.K.) and Dr. Davis Kibirige (Uganda Martyrs Hospital Lubaga Kampala, Uganda) and for valuable help in writing and editing from Caroline Boyle (Albert Einstein College of Medicine, Bronx, New York) and Dr. Monica F.N. Cordeiro (Albert Einstein College of Medicine, Bronx, New York).

Funding. M.H. receives salary support from the National Institute of Diabetes and Digestive and Kidney Diseases (R01 DK069861).
