INTRODUCTION

Incidence rate of Covid-19 infection is still increasing exponentially over the globe despite the availability of different vaccines to protect the infection. According to World Health Organization (WHO) report of June 2021 more than 179 million people are infected with Covid-19 and 3.8 million people are dead due to the present pandemic. Higher risk of acquiring the infection has been found to be linked with chronic diseases (e.g., lung or cardiovascular), hypertension and diabetes mellitus. Clinical severity of an existing
Covid-19 infection can be determined by using CRP, ferritin and LDH but there is no known biological marker to predict the risk of acquiring the infection before the onset of the disease.\(^3\)

ABO blood grouping system is a type of cell identification system which was discovered by Landsteiner. This system is based on the presence of blood group antigens (A & B) and their respective antibodies (Anti-A & Anti-B) in the blood. According to this system, there are four types of phenotypes accepted universally as A, B, O and AB. Rh factor determines the presence or absence of specific antigenic structures and it can be positive or negative.\(^5\)

Few studies have reported the association between ABO blood group types and viral infections (hepatitis B, Norwalk virus), rheumatological diseases, and cancer.\(^4\) Antigenic determinants of ABO blood group types were found to be associated with the increased susceptibility of acquiring viral infections. SARS-COV-2 virus, major cause of deadly pandemic of Covid-19 infection, has been found to be linked with the presence of AB antigens where individuals with A/B/AB blood groups are at greater risk of getting the infection as compared to individual without AB antigens (blood group: O).\(^6\) This relationship of AB antigens with higher risk of acquiring infection has been reported in very few studies in literature. More studies are warranted to examine the link of ABO blood group types with this deadly viral infection and reveal the vulnerability of different blood group individuals to acquire the infection.\(^7\)

Association of SARS-COV-1 virus with ABO blood groups has been assessed previously. Such association was first reported by Zhao et al., for SARS-COV-2 virus and indicated that individuals with A blood group are at greater risk of acquiring Covid-19 infection than other blood groups. They concluded that blood group O’ individuals are at decreased risk of getting the infection.\(^8\) Few reports are available in support of these findings. Despite available studies specific biological markers to predict the risk of acquiring Covid-19 infection are still lacking.

Previously available studies were carried out using the antibodies of AB antigens such as anti-A (blood group B & O), anti-B (blood group A & O) and found that Anti-A antibodies have weak association with the risk of getting the infection as compared to other antibodies.\(^9\) Contrasting results has been reported by Latz et al.,\(^10\) where individuals with B blood groups were found to be at higher risk instead of A. This recent report urges more investigations to solve the ambiguity. Moreover, to the best of our knowledge, there is no study reporting the association of Rh factor with susceptibility and severity of Covid-19 infection. Therefore, present study was designed to examine the association of ABO blood group types and Rh factor distribution with risk and severity of the Covid-19 infection along with its relationship with clinical characteristics in Covid-19 patients.

**METHODS**

This observational cross-sectional study was approved by the Institutional Review Board of Pakistan Ordnance Factory (POF) Hospital Wah Cantt, Pakistan (IRB No. POFH/ERC/99053/07, Dated: 16/03/2020) and performed in accordance with the principles of declaration of Helsinki. This study was conducted at department of Medicine of POF hospital from August 2020 to December 2020. Written informed consent was taken from all enrolled patients. A total of 248 patients having Covid-19 infection and admitted in ward (IPD) or ICU were enrolled randomly for this study.

Covid-19 patients with positive polymerase chain reaction (PCR) test and reported blood group information were included in the study by random sampling while patients without this information were excluded. Medical record of all enrolled patients was reviewed and clinical features along with basic demographics, and laboratory findings [such as lab reports (Complete blood count (CBC), C-reactive proteins (CRP), Alanine transaminase (ALT), Renal function tests (RFTs), Creatine phosphokinase (CPK), Lactate dehydrogenase (LDH), ferritin, Arterial blood gases (ABG’s), D-dimers and Coagulation profile), and Radiological assessment by initial chest X-rays (CXR) and High-Resolution Computed Tomography (HRCT) chest] were noted. Patients tested positive for Covid-19 via both nasopharyngeal (NP) and throat swab were enrolled. ABO blood group and Rh factor data for all the Covid-19 infected patients were obtained from the laboratory section of the hospital and analyzed. Rh factor was determined by using anti-D and ABO blood grouping was performed by test tube method and DIAGAST reagent was used. Polymerase chain reaction (PCR) was used to detect the presence of E gene for Covid-19 infection in the sample and positive PCR sample was subjected to confirmation by targeting RdRp. Realtime PCR kits to detect the Covid-19 infection were obtained from Roche and Invitrogen.
A structured proforma was used to enter all findings. Covid-19 infection severity was measured through mild, moderate and severe disease categories and analyzed. Covid-19 severity as follows; Mild (mild clinical symptoms, no oxygen requirement, no pneumonia on chest X-rays or HRCT chest), Moderate (fever, cough and lung CT with pneumonia (lung infiltrates less than 40%), SpO₂ greater than 93%, may have mild oxygen requirement via nasal cannula or simple face mask or low concentration via venturi mask) and Severe (symptoms of respiratory distress i.e., respiratory rate greater than 30/minutes with SpO₂ less than 93% at rest and/or ratio of arterial oxygen partial pressure to fractional inspired oxygen less than 300mmHg (PaO₂/FiO₂), or may require oxygen through NRM (Non re-breathable mask), higher oxygen concentration via venturi or non-invasive or invasive ventilation, ARDS or shock). The severity of disease was as follows; Mild (mild clinical symptoms, no oxygen requirement, no pneumonia on chest X-rays or HRCT chest), Moderate (fever, cough and lung CT with pneumonia (lung infiltrates less than 40%), SpO₂ greater than 93%, may have mild oxygen requirement via nasal cannula or simple face mask or low concentration via venturi mask) and Severe (symptoms of respiratory distress i.e., respiratory rate greater than 30/minutes with SpO₂ less than 93% at rest and/or ratio of arterial oxygen partial pressure to fractional inspired oxygen less than 300mmHg (PaO₂/FiO₂), or may require oxygen through NRM (Non re-breathable mask), higher oxygen concentration via venturi or non-invasive or invasive ventilation, ARDS or shock). Socio-demographic factors like age, gender, hypertension, diabetes, and abovementioned clinical information of Covid-19 were also noted. For statistical analysis the data was entered in SPSS version 26. Means and standard deviations were calculated for quantitative variables like age. Frequencies were calculated for gender, hypertension and diabetes. Chi-square test and odds ratio (ORs) with 95% confidence intervals was used for ABO blood group types and Rh factor frequency in all patients. Cox regression model was used for the analysis of the association between the ABO blood group types, Rh factor and severity of disease. A p value ≤ 0.05 was considered significant.

RESULTS

Total 248 Covid-19 positive patients were included for the study; 75.0% (n=186) were male patients and 25.0% (n=62) were females. Also, the mean age of the patients was 52.77±15.58 years. Comorbidities like hypertension (HTN), diabetes mellitus (DM), ischemic heart disease (IHD), and stroke etc., were studied. Out of 248 Covid-19 positive patients, 20.2% (n=50) were hypertensive, 15.3% (n=38) diabetes mellitus, 4.8% (n=12) had ischemic heart disease, 1.6% (n=4) were stroke patients, 1.6% (n=4) had multiple comorbidities DM/HTN/IHD and 56.5% (n=140) were no history of any comorbidity. Percentage frequency of all blood group types of enrolled patients is shown in (Fig. 1). Briefly, frequency of A, B, AB and O blood groups was 17.7%, 39.5%, 12.1% and 30.6% respectively. Rh+ and Rh- blood group distribution was 88.7% and 11.3% respectively. Stratification analysis was performed by gender based, the association analysis revealed insignificant relation (p ≥ 0.05) between ABO blood group and Covid-19 in male and female subgroups (Table-I). We determine the ABO blood type with Rh blood distribution and stratification analysis was performed by severity of disease based, the association analysis revealed significant relation (p ≤ 0.05) between ABO & Rh blood group and severity of Covid-19 patients (Table-II). The severity of disease table showed, more patients of
blood group B+ and blood group O+ were severe with Covid-19 as compare to other blood types.

Also, ABO blood group types and Rh factor distribution was stratified by health status of all Covid-19 positive patients (Table-III). There were 242 (97.6%) Covid-19 positive patients alive and 6 (2.4%) patients were died. There were 4 patients of blood group B+ and 2 patients of blood group O+ were died. The association revealed significant (Fisher’s exact test = 17.854, and p=0.013), when compare ABO & Rh blood group types and Covid-19 in health status of all patients.

The disease severity analysis shows an average of blood group B+ (3.2%) and O+ (2.5%) had severe disease. Patients of these blood groups also have higher percentage in mild and moderate disease severity groups which is 23.4% and 16.9% in mild disease severity group respectively. In moderate disease severity group is an average of 8.9%

### Table-I: Stratified analysis of ABO blood group types by gender based, n=248.

| Blood group | Gender | Frequency (%) | Chi square | p-value | OR (95% CI) |
|-------------|--------|---------------|------------|---------|-------------|
| A           | Male   | 34 (13.7%)    | 0.147      | 0.701   | 0.86 (0.39-1.86) |
|             | Female | 10 (4.1%)     |            |         |             |
| B           | Male   | 70 (28.2%)    | 1.102      | 0.29    | 1.37 (0.76-2.44) |
|             | Female | 28 (11.2%)    |            |         |             |
| AB          | Male   | 22 (8.9%)     | 0.051      | 0.822   | 1.11 (0.47-2.63) |
|             | Female | 8 (3.2%)      |            |         |             |
| O           | Male   | 60 (24.2%)    | 0.911      | 0.340   | 0.73 (0.38-1.39) |
|             | Female | 16 (6.5%)     |            |         |             |

OR: odds ratio adjusted with; CI: confidence interval.

### Table-II: Stratified analysis of ABO blood group types, Rh factor by severity of disease, n=248.

| ABO blood group | Mild | Moderate | Severe | Total |
|-----------------|------|----------|--------|-------|
| A+              | 29 (11.7%) | 10 (4%) | 1 (0.4%) | 40 |
| A-              | 3 (1.2%) | 1 (0.4%) | 0 | 4 |
| B+              | 58 (23.4%) | 22 (8.9%) | 8 (3.2%) | 88 |
| B-              | 7 (2.8%) | 3 (1.2%) | 0 | 10 |
| AB+             | 18 (7.3%) | 5 (2%) | 1 (0.4%) | 24 |
| AB-             | 4 (1.6%) | 2 (0.8%) | 0 | 6 |
| O+              | 42 (16.9%) | 20 (8.1%) | 6 (2.5%) | 68 |
| O-              | 5 (2%) | 3 (1.2%) | 0 | 8 |
| Total           | 166 (66.9%) | 66 (26.6%) | 16 (6.5%) | 248 |

Fisher’s Exact Test value = 41.547, p value = 0.001.

### Table-III: Stratified analysis of ABO blood group types, Rh factor by health status, n=248.

| ABO blood group | Alive | Expired | Total |
|-----------------|-------|---------|-------|
| A+              | 40    | 0       | 40 |
| A-              | 4     | 0       | 4 |
| B+              | 84 (95.5%) | 4 (4.5%) | 88 |
| B-              | 10    | 0       | 10 |
| AB+             | 24    | 0       | 24 |
| AB-             | 6     | 0       | 6 |
| O+              | 66 (97.1%) | 2 (2.9%) | 68 |
| O-              | 8     | 0       | 8 |
| Total           | 242 (97.6%) | 6 (2.4%) | 248 |

Fisher’s Exact Test value = 17.854, p value = 0.013.
Table-IV Cox regression: “Exp(B)” values showed, there is an association between blood group B+ and O+ type and severity of Covid-19 positive patients (values = 0.947 and 0.279, respectively which is ≤ 1). Other blood group types have weak association.

The comparison between ABO blood group types and Rh factor with severity of disease, Cox regression model was done and the graph shows the frequency of blood group B+ and O+ type more severe to Covid-19 positive patients is shown in Fig-2. Other blood group types show there is a week association between them.

**DISCUSSION**

Analyzing the data obtained from 248 patients of Covid-19 infection, we found that frequency of B+ and O+ blood group was higher than other blood groups. Statistical analysis revealed a significant association of ABO blood group types and Rh factor with severity of Covid-19 infection (p = 0.001). It was also observed when stratified ABO, Rh blood group with health status of all patients there was a very significant association between them (p = 0.013). Our results also demonstrated that there was an insignificant association between male and female odds ratio of ABO blood group types but blood group B was found to be more susceptible in Covid-19 positive patients.

Previously, a study performed by Fan et al. in Wuhan China, reported a significant association of A blood group with Covid-19 infection. They also found that females with blood group A are more susceptible (relative risk: 1.33) to acquire Covid-19
infection as compared to males. Whereas, in this study we found that males with blood group B are more susceptible to get Covid-19 infection. The odd ratio of blood group B was found to be 1.37 in this study. Another study conducted by Xiong et al. reported that Covid-19 transmission pattern in females is entirely different from males due to their different hormonal level, immune system, anatomic features and genetic makeup.

Study of this qualitative identification system of the cells is of higher importance as it is not affected by environmental factors and the presence of a particular phenotype depends on its genetic makeup only. Genes associated with blood group antigens can be a predisposing factor or a protective factor for different diseases. Susceptibility to acquire infections may increase or decrease depending on the expression of different blood group antigens. These blood group antigens play a vital role in the onset of different infections as they can act as cofactors or receptors for different types of microorganisms (e.g., viruses, bacteria, and parasites). They also play a vital role in signal transduction, cell adhesion and intracellular uptake by organization of membrane microdomains. They are also shown to completely modify the immune response of an individual to an infection.

Since the onset of the pandemic, available literature on Covid-19 is increasing on daily basis. More and more researches are going on to control and prevent the pandemic situation. Zhao et al. examined the relationship of ABO blood group types, Rh factor and Covid-19 infection. We also determined the ABO blood group types and Rh factor may determine the greater susceptibility to the disease and also affect the course of the disease. It can be investigated in future as a potential biomarker to predict the risk of Covid-19 infection. Present study emphasizes that ABO blood grouping was statistically significant with severity of disease as well as health status of patients. Present study suggest that ABO blood group types can be a useful tool to predict the susceptibility as well as severity of Covid-19 infection. We suggest multi-center studies on larger scale community by using this tool with a control group and also include the “Delta variant” patients to see its severity with Covid-19 positive patients.

CONCLUSION

Our study concluded that ABO blood grouping and Rh factor (mostly B+ and O+) are associated with the severity of Covid-19 infection. ABO blood group types and Rh factor may determine the greater susceptibility to the disease and also affect the course of the disease. It can be investigated in future as a potential biomarker to predict the risk of Covid-19 infection. Present study emphasizes that following the SOPs (e.g., maintain social distance, hand hygiene and use of masks) is still the most important way to prevent Covid-19 infection regardless of the presence of risk and facilitating factors.

Grant Support & Financial Disclosures: None.
