\textbf{ABSTRACT}

Objectives: The evaluation of Mutans streptococci (MS) is one of the index for caries risk. Dentocult\textsuperscript{TM} and CRT\textsuperscript{TM} are commercial kits to detect and evaluate MS, conveniently. However, the evaluation of MS has also been carried out simply using an instruction manual. But the instruction manual is not easy to use for evaluation of MS. The aim of this study was to examine the utility of modified Mitis-Salivarius Bacitracin (MSB) agar medium compared with MSB agar medium and commercial kits, and to establish a convenient kit (mMSB-kit) using modified MSB agar.

Methods: The MS in stimulated saliva from 27 subjects were detected by MSB, modified MSB agar medium and commercial kits. Laboratory and clinically isolated strains of MS were similarly evaluated. The ratios of MS in detected bacteria were compared by ELISA.

Results: The scores using an mMSB-kit on the basis of modified MSB agar medium were tabulated. Saliva samples showed different levels of MS between culture methods and the commercial kit. Some samples which were full of MS were not detected by the commercial kit. The detection of MS by modified MSB agar medium and mMSB-kit were significantly higher when compared with MSB agar medium, CRT\textsuperscript{TM}, [P<.01] and Dentocult SM\textsuperscript{TM} [P<.05].

Conclusion: The sensitivity for detection of MS is higher for modified MSB agar medium when compared with MSB agar medium. The mMSB-kit can be used simply, and can be an important contributor for the evaluation of MS as a caries risk factor. [Eur J Dent 2007;1:31-39]

Key words: Commercial kits; Culture methods; \textit{Streptococci mutans}; \textit{Streptococcus sobrinus}.

\textbf{INTRODUCTION}

Dental caries has a multifactorial etiology. It has been suggested to be triggered by three main factors: host, environment and bacteria.\textsuperscript{1,2} Mutans streptococci (MS) and lactobacilli are well known as cariogenic oral bacteria.\textsuperscript{3,4} MS including \textit{Streptococcus mutans} (S. mutans) and \textit{Streptococcus sobrinus} (S. sobrinus) are well known as a group of oral microorganisms which have virulence factors and which are harbored on the tooth surface within the oral biofilm. The key virulence factors are synthesized water insoluble glucan from sucrose, acidogenicity and acid tolerance.\textsuperscript{5-7} Among the three factors described above, bacteria have been suggested to have the strongest effect on the prevalence or incidence of dental caries.\textsuperscript{8-10} Therefore, it is necessary to establish an accurate method for the detection and evaluation of these bacteria. Mitis-Salivarius Bacitracin (MSB) agar is the conventional culture medium and is known as a method to selectively detect MS.\textsuperscript{11} However, clinical studies suggest that MS are not detected in the patients with high levels of total number of Decayed, Missing and Filling teeth as DMF. In contrast, these bacteria are detected at high levels in subjects with no dental caries.\textsuperscript{12,13} These results show that the specificity of the test is not always high.\textsuperscript{14,15} Additionally, other bacteria also grow sometimes in this medium. Furthermore, to carry out conventional bacterial culture methods, ex-
Materials and Methods

**Bacterial strains**

Laboratory strains used in this study were 5 strains of *S. mutans* ([S. mutans] 8148, LM7, EM2, Ingbritt, OMZ 175) and 4 strains of *S. sobrinus* ([S. sobrinus] 6715, 33478, AHT, OMZ176). Bacterial cultures were stored at -80°C in Brain Heart Infusion (BHI: Difco, Tokyo, JAPAN) broth containing 50% glycerol (stock solution). These bacteria were obtained from ATCC, and stocked in the National Institute of Public Health in Japan. Clinically isolated strains were obtained from stimulated saliva samples. The clinical isolated strains of *S. mutans* and *S. sobrinus* were also carried out, because it has suggested *S. mutans* and *S. sobrinus* acquire the antibiotic-resistance by natural genetic transformation. In addition, we developed a convenient kit (mMSB-kit) using modified MSB agar medium and evaluated the utility of the modified MSB agar medium.

**Identification of clinically isolated strains**

Clinically isolated strains were identified by polymerase chain reaction (PCR), and DNA extraction from *S. mutans* and *S. sobrinus* was done using DNeasy kits (Qiagen, Tokyo, JAPAN). Gene sequences were amplified with primers GTF-B, GTF-I and taq DNA polymerase (Premix Taq; Takara Bio Inc., Shiga, JAPAN). Reaction mixtures and PCR cycles were as previously described.20, 21 The sequences of primers used in this study were GTF-B 5’-ACTACACTTTCGTTGCGTGCGTGG-3’ for *S. mutans* and GTF-I 5’-GATAACTCCTGACAGCTGACT-3’ for *S. sobrinus*. Primer GTF-B was designed to amplify a 517 bp DNA fragment of gtfB sequence of *S. muta-
Tans. Primer GTF-I was designed to amplify a 712 bp DNA fragment of the gtfI sequence of *S. sobrinus*. The amplification was performed in a thermocycler (Takara Bio Inc., Shiga, JAPAN) with an initial denaturation at 95°C for 5 min, followed by 40 cycles of denaturation (95°C, 30 sec), annealing (59°C, 30 sec) and extension (72°C, 1 min). The final extension step was at 72°C for 7 min. The PCR products were resolved by electrophoresis through 1.8% TBE agarose gels with 0.5 µg/ml ethidium bromide. Gels were photographed under UV trans illuminator (Funakoshi, Tokyo, JAPAN).

**Evaluation of laboratory strains and clinical isolated strains**

Laboratory strains and clinically isolated strains of *S. mutans* and *S. sobrinus* were cultured in BHI broth and incubated at 37°C for 18 hours. Following incubation, bacterial cultures were centrifuged (2500 rpm x 20 min), washed, and adjusted, using PBS, to an optical density (OD540) of 1.0. For detection of MS, concentrated bacterial suspensions were serially diluted from 1/10 to 1/10^4 with PBS and inoculated on Dentocult SM™, CRT™, MSB agar medium, modified MSB agar medium or BHI supplemented 1.5% agar (Difco, Tokyo, JAPAN) as a control plate. Each culture method and evaluation method was carried out similarly for clinical samples.

**Ratio of cariogenic bacteria**

For detection of *S. mutans* and *S. sobrinus*, total streptococci on each medium were calculated by Enzyme Linked Immunosorbent Assay (ELISA). The colonies were isolated in each medium for four typical subjects who showed different values in this study for detection of *S. mutans* and *S. sobrinus* by Dentocult SM™, CRT™ and MSB agar medium methods. Then, the isolated colonies were inoculated into 24 well microtiter plates (Sumitomo Bakelite, Tokyo JAPAN) in BHI broth. Following incubation at 37°C for 24 hours, the bacterial cells were harvested by centrifugation (2500 rpm x 20 min) and washed twice with PBS. For the ELISA, 96 well microtiter plates (Sumitomo Bakelite, Tokyo JAPAN) were coated with each bacteria solution and coating buffer solution for 18 hours at 37°C. After drying the plate, it was washed with PBS containing 0.1% Tween 20 (PBST) and blocked with 1% skim milk in PBST for 1h at 37°C. Excess milk was removed and the plate was washed twice with PBST. Then the first antibodies -IH5-H4-C6 for *S. mutans* and IG6-A3-E4 for *S. sobrinus* – were added to the wells and incubated for 1 hour at 37°C. The wells were then washed twice with PBST and further incubated for an hour at 37°C with alkaline phosphatase-conjugated affinity purified goat anti mouse IgG + IgM (Jackson Immuno Research Laboratories, PHL, USA). After washing twice with PBST, bound antibodies were detected by addition of disodium nitrophenyl phosphate hexahydrate (Wako Pure Chemicals Co., Osaka, JAPAN) for 30 minutes at 37°C. The absorbance at 405 nm was measured with a micro-plate reader (MPR: Toso, Tokyo, JAPAN).

**Estimation of MS by mMSB-kit**

Four scores for detection of MS using the mMSB-kit were defined as follows: a score of 3: >6 log_{10} CFU/ml, score 2: 6-5 log_{10} CFU/ml, score 0-1: <5 log_{10} CFU/ml. The scores were based on epidemiological studies for cariogenic bacteria in this study for detection of *S. mutans* and *S. sobrinus* by Dentocult SM™, CRT™ and MSB agar medium methods. Then, the isolated colonies were inoculated into 24 well microtiter plates (Sumitomo Bakelite, Tokyo JAPAN) in BHI broth. Following incubation at 37°C for 24 hours, the bacterial cells were harvested by centrifugation (2500 rpm x 20 min) and washed twice with PBS. For the ELISA, 96 well microtiter plates (Sumitomo Bakelite, Tokyo JAPAN) were coated with each bacteria solution and coating buffer solution for 18 hours at 37°C. After drying the plate, it was washed with PBS containing 0.1% Tween 20 (PBST) and blocked with 1% skim milk in PBST for 1h at 37°C. Excess milk was removed and the plate was washed twice with PBST. Then the first antibodies –IH5-H4-C6 for *S. mutans* and IG6-A3-E4 for *S. sobrinus* – were added to the wells and incubated for 1 hour at 37°C. The wells were then washed twice with PBST and further incubated for an hour at 37°C with alkaline phosphatase-conjugated affinity purified goat anti mouse IgG + IgM (Jackson Immuno Research Laboratories, PHL, USA). After washing twice with PBST, bound antibodies were detected by addition of disodium nitrophenyl phosphate hexahydrate (Wako Pure Chemicals Co., Osaka, JAPAN) for 30 minutes at 37°C. The absorbance at 405 nm was measured with a micro-plate reader (MPR: Toso, Tokyo, JAPAN).

*Figure 1.* Difference in the detection of MS comparing score or value of MSB agar medium, Dentocult SM™ and CRT™.
and experiments on dental caries.\textsuperscript{22-25} Data on the detection of MS by Dentocult SM\textsuperscript{TM}, CRT\textsuperscript{TM} and MSB agar medium were confirmed by mMSB-kit and modified MSB agar medium. After 2 days, saliva samples were again collected from subjects, and cultured using the mMSB-kit and modified MSB agar medium. Detection of MS by mMSB-kit was evaluated and compared with estimates for the modified MSB agar medium.

\section*{Statistical analysis}
Three replicates were done for each concentration of the tested extracts for all assays. Each value represents the mean ± standard deviation for assays. Correlations for the detection of MS on MSB agar medium, Dentocult SM\textsuperscript{TM} and CRT\textsuperscript{TM} were analyzed using Spearman’s rho. The level of significance for all statistical tests was set at P<.05. Differences in detection of MS were analyzed using the Mann-Whitney U test.

\section*{RESULTS}
\subsection*{Clinical samples}
All subjects who participated in this study were healthy and without any chronic disease or daily intake of medicines. The characteristics of the subjects and the detection of MS by MSB agar medium, modified MSB agar medium, Dentocult SM\textsuperscript{TM} and CRT\textsuperscript{TM} are shown in Table 1. Experience of dental caries was as follows: number of filled teeth ranged from 0-27, missing teeth from 0-2, decayed teeth 0 (by oral examination). Figure 1 summarizes the estimation of MS which showed the different corresponding values or scores of MSB agar plate, Dentocult SM\textsuperscript{TM} and CRT\textsuperscript{TM} for the three of nine subjects. Levels of MS were compared among MSB agar medium and Dentocult SM\textsuperscript{TM} or CRT\textsuperscript{TM} and this is shown in Figure 2a-b. There was a positive association between MSB agar medium and Dentocult SM\textsuperscript{TM} (P<.05, rs=0.53), whereas MSB agar medium and CRT\textsuperscript{TM} showed no correlation (P<.05, rs=0.30).

\subsection*{Estimation of cariogenic bacteria}
For clinical strains, we evaluated MS from 9 subjects and for 7 strains of \textit{S. mutans} and 2 strains of \textit{S. sobrinus}. Table 2a-c summarizes the detection of \textit{S. mutans} and \textit{S. sobrinus} in laboratory and clinically isolated strains with MSB agar medium, modified MSB agar medium, BHI agar medium, Dentocult SM\textsuperscript{TM} and CRT\textsuperscript{TM}. Inconsistent results for MS detection were observed for the conventional

culture methods and the commercial kit. Also, a few bacteria were not detected by the commercial kit.

**Ratio of cariogenic bacteria**

Figure 3 summarizes the ratio of cariogenic bacteria to total streptococci when antibodies for *S. mutans* and *S. sobrinus* and identification with ELISA were used. Levels of cariogenic bacteria in each subject analyzed with MSB agar medium, modified MSB agar medium, commercialized kits and mMSB-kit for detection of *S. mutans* and *S. sobrinus*. Modified MSB agar medium and mMSB-kit were significantly higher when compared with MSB agar medium, CRT™ [P<.01] and Dentocult SM™ [P<.05]. There was no significant difference between results for modified MSB agar medium and mMSB-kit.

**Evaluation of MS by mMSB-kit**

The mMSB-kit was compared with modified MSB medium. The typical classification using 4 scores for detection of *S. mutans* and *S. sobrinus* are shown in Figure 4. The typical class score 3 corresponds to about 6 log<sub>10</sub> CFU/ml, score 2 corresponds to between 5-6 log<sub>10</sub> CFU/ml, and score 0-1 corresponds to <5 log<sub>10</sub> CFU/ml. Saliva of 25 subjects was again collected and cultured by Table 2a.

Each value represents the mean ± standard deviation for assays performed three times. - indicates under the detection limit.

Figure 2a. Detection of MS was compared between MSB agar medium and Dentocult SM™. The detection limits for MS on MSB agar plates were 0. Score for Dentocult SM™ and CRT™ are as follows, score 3: >6 log_{10} CFU/ml, score 2: 6-5 log_{10} CFU/ml, score 0-1: <5 log_{10} CFU/ml.

There was a positive association between MSB agar medium and Dentocult SM™ (P<0.05, rs=0.53), whereas MSB agar medium and CRT™ showed no correlation (P<0.05, rs=0.30) by Spearman.

Figure 2b. Detection of MS was compared between MSB agar medium and CRT™. The detection limits for MS on MSB agar plates were 0. Score for Dentocult SM™ and CRT™ are as follows, score 3: >6 log_{10} CFU/ml, score 2: 6-5 log_{10} CFU/ml, score 0-1: <5 log_{10} CFU/ml.

There was a positive association between MSB agar medium and Dentocult SM™ (P<0.05, rs=0.53), whereas MSB agar medium and CRT™ showed no correlation (P<0.05, rs=0.30) by Spearman.

Table 3. Ratios of S. mutans and S. sobrinus calculated by different methods.

mMSB-kit and results were compared with those for modified MSB agar medium (Figure 5). There was a positive association between modified MSB agar medium and mMSB-kit \((P < 0.01, \text{rs}=0.84)\).

**DISCUSSION**

Dental caries is a multifactorial disease which is complicated by host environmental and bacterial factors. At the present time, it is necessary to be aware of these factors and to establish preventive programs taking all of these factors into account. It is especially important to comprehend the contribution of bacteria, which has been suggested to be the most prominent factor in dental caries.\(^{26-30}\) In our study, each mMSB-kit was made from modified MSB agar medium which increased detection of *S. mutans* and *S. sobrinus*. This kit was compared with MSB agar medium, modified agar medium, Dentocult SM\(^\text{TM}\) and CRT\(^\text{TM}\) in the analysis of saliva samples from subjects, from laboratory specimens, and from clinically isolated strains of *S. mutans* and *S. sobrinus*. A difference was recognized for several methods. Accurate evaluation can not always be obtained as a different result is obtained by conventional culture methods and by commercial kits. In fact, it is possible to eval-

---

**Figure 3.** Ratios of *S. mutans* and *S. sobrinus* calculated by different methods.

Differences in the ratio of *S. mutans* and *S. sobrinus* were different for modified MSB agar medium and mMSB-kit compared to the Dentocult SM\(^\text{TM}\) \((P < 0.05\): Mann-Whitney test), CRT\(^\text{TM}\) and MSB agar medium \((P < 0.01\): Mann-Whitney test). However, differences in the *S. mutans* and *S. sobrinus* ratios were not significant between the Dentocult SM\(^\text{TM}\), CRT\(^\text{TM}\) and MSB agar medium.

**Figure 4.** Classification score for detection of *S. mutans* and *S. sobrinus* by mMSB-kit.

**Figure 5.** Comparison between mMSB-kit and modified MSB agar medium for detection of MS. There was a positive association between modified MSB agar medium and mMSB-kit \((P < 0.01, \text{rs}=0.84)\) by Spearman.
ate a patient as being at high risk for dental caries because of an "apparent" large amount of bacteria is detected by commercial kits. In contrast, it is possible to evaluate a patient as being at low risk of dental caries because of the existence of bacteria which were not detected. In these cases, it has been ungraspable to evaluate the bacteria factor accurately. One reason for the different results may be that one strain of *S. mutans* does not grow on MSB agar medium due to lack of tolerance to Bacitracin. It has been reported that the virulence of *S. sobrinus* is equal to or higher than that of *S. mutans*. As for synergy effect, the caries risk is increased more for a single infection of *S. mutans* than for a mixed infection of *S. mutans* and *S. sobrinus*. Epidemiological studies of the relationship between the experience of dental caries and caries risk report that the caries risk of subjects who possess both *S. mutans* and *S. sobrinus* is higher than that for subjects possessing only *S. mutans* or only *S. sobrinus*. Therefore, to evaluate caries risk in terms of the bacterial factor, it is important to evaluate not only the total amount of *S. mutans* and *S. sobrinus*, but also the amounts of each. Several methods for detection and identification of *S. mutans* and *S. sobrinus* have been reported for selective media and subsequent biochemical or serological tests and DNA probe methods. Recently, selective culture techniques for *S. sobrinus* have been reported. The modified MSB agar medium also uses Bacitracin, but to prevent tolerance of MS to Bacitracin, Colistin, Nalidixic Acid and Gramicidin are added. Furthermore, Yeast Extract is added to promote cell growth. Several methods were used to identify *S. mutans* and *S. sobrinus* by ELISA. The modified MSB agar medium showed significantly higher levels of *S. mutans* and *S. sobrinus* when compared with conventional culture methods of MSB agar medium and commercial kits. The mMSB-kit was used to modify the MSB agar medium, which also showed high levels of detection of *S. mutans* and *S. sobrinus*. Detection of MS by modified MSB agar medium is reproducible. The formation of commercial kits made using MSB agar medium are different from conventional formation of MSB agar medium. The composition of conventional MSB agar medium is adjusted for Bacitracin and sucrose by 0.2U and 20% respectively. In contrast, Dentocult SM™ had a consistency of 0.26U and 30%, and CRT™ a consistency of sucrose 41%. It has been reported that growth of *S. mutans* and *S. sobrinus* is inhibited by no less than 0.3 U of Bacitracin and no less than 30% sucrose. It has thought of as mass of detection of MS by commercial kit for effects of these compositions. Natural genetic transformation is a process by which bacteria are able to take up and integrate exogenous free DNA from their environment. This process enables the recipient organisms to acquire novel genes or heritable traits, thereby promoting the emergence of antibiotic resistance and genetic variation and the rapid evolution of virulence. The rapid emergence and spread of antibiotic resistance is probably the most commonly recognized manifestation of this process. The MSB agar medium is possible that detection of *S. mutans* and *S. sobrinus* selectively show the resistance of Bacitracin all but a few of *S. sobrinus*. For the appearance of resistant bacteria, non-MS have the possibility to evaluate as cariogenic bacteria in Japan which has prescribed for large quantities antibiotic. Previous studies have reported that salivary levels of *S. mutans* can be used to predict caries risk. *S. mutans* counts >6 log₅ CFU/ml in saliva indicates a high caries risk. Meanwhile, the odds ratio of detection of MS by commercial kit (odds ratio of scores 1, 2, and 3 were 1.4, 6.5 and 8.9, respectively) is higher than not detection or detection limit of *S. mutans* and *S. sobrinus* as score 0 for infants. The score for the mMSB-kit has been classified according to this report. Therefore, the score is able to be used to predict the value of *S. mutans* and *S. sobrinus* and therefore the caries risk. The mMSB-kit also shows a positive correlation (rs=0.84) for recollected saliva sample. Consequently, mMSB-kit has been re-creation faithfully of modified MSB agar medium as these results show. Moreover, the sensitivity of detecting MS is higher by modified MSB agar medium when compared with conventional MSB agar medium, and an mMSB-kit is able to be used simply and at the chair side.

**CONCLUSIONS**

We conclude that application of mMSB-kits and scores for the classifications they report are useful in that they allow accurate evaluation of MS and caries risk in clinical use.
