Abstract

We consider the problem of online prediction in a marginally stable linear dynamical system subject to bounded adversarial or (non-isotropic) stochastic perturbations. This poses two challenges. Firstly, the system is in general unidentifiable, so recent and classical results on parameter recovery do not apply. Secondly, because we allow the system to be marginally stable, the state can grow polynomially with time; this causes standard regret bounds in online convex optimization to be vacuous. In spite of these challenges, we show that the online least-squares algorithm achieves sublinear regret (improvable to polylogarithmic in the stochastic setting), with polynomial dependence on the system’s parameters. This requires a refined regret analysis, including a structural lemma showing the current state of the system to be a small linear combination of past states, even if the state grows polynomially. By applying our techniques to learning an autoregressive filter, we also achieve logarithmic regret in the partially observed setting under Gaussian noise, with polynomial dependence on the memory of the associated Kalman filter.

1 Introduction

We consider the problem of sequential state prediction in a linear time-invariant dynamical system, subject to perturbations:

\[ x_t = Ax_{t-1} + Bu_{t-1} + \xi_t. \]

This is a central object of study in control theory and time-series analysis, dating back to the foundational work of Kalman [Kal60], and has recently received considerable attention from the machine learning community. In a typical learning setting, the system parameters \( A, B \) are unknown, and only the past states \( x_t \) and exogenous inputs \( u_t \) are observed. Sometimes, another layer of difficulty is imposed: the latent state \( x_t \) can only be observed noisily or through a low-rank transformation. These models serve as an abstraction for learning from correlated data in stateful environments, and have helped to understand empirical successes in reinforcement learning and of recurrent neural networks.

Many recent works are concerned with finite-sample system identification, in which the matrices \( A, B \) can be recovered due to structure in the perturbations or inputs. These results rely on matrix
concentration inequalities and careful error propagation applied to classic primitives in linear system identification, and have settled some important statistical questions about these methods. However, as in the classical control theory literature, these theorems require unrealistic assumptions of i.i.d. isotropic random perturbations and recoverability of the system, and often require the user to select the “exploration” inputs $u_t$. Furthermore, under model misspecification, the guarantees of parameter identification pipelines break down.

Another line of work seeks to obtain more flexible guarantees via the online learning framework. Here, the goal of parameter recovery is replaced with regret minimization, the excess prediction loss compared to the best-fit system parameters in hindsight. This approach gives rise to algorithms which adapt to adversarially perturbed data and model misspecification, and can be extended beyond prediction to obtain new methods for robust control. However, these algorithms can diverge significantly from the classical parameter identification pipeline. In particular, they can be improper, in that they may use an intentionally misspecified (e.g. overparameterized) model. Thus, these algorithms can be incompatible with parameter recovery and downstream methods.

In this work, we show that the same algorithm used for parameter identification (online least squares) has a no-regret guarantee, even in the challenging setting of prediction under marginal stability and adversarial perturbations, where recovery is impossible. More precisely, in this setting, where the state is allowed to grow polynomially with time, we show that the regret of this algorithm is sublinear, with a polynomial dependence on the system’s parameters. This does not follow from the usual analysis of online least squares: the magnitude of loss functions (and associated gradient bounds) can scale polynomially with time, causing standard regret bounds to become vacuous. Instead, we conduct a refined regret analysis, including a structural volume doubling lemma showing $x_t$ to be a small linear combination of past states.

By replacing the worst-case structural lemma with a stronger martingale analysis, we also show a polylogarithmic regret bound for least squares in the stochastic setting. Again, this analysis does not go through parameter convergence, and thus applies in the setting of unidentifiable systems and non-isotropic noise. The same techniques allow us to prove a logarithmic regret bound in the partially observed setting under Gaussian noise, with polynomial dependence on the memory of the associated Kalman filter.

**Paper structure.** This paper is organized as follows. In Section 2, we formally introduce the problem and the natural online least squares algorithm. In Section 3, we give an overview of related work. In Section 4, we state our main results. In Section 5, we sketch the proofs. In Section 6, we show that a structural condition on a time series gives a regret bound for online least squares. We then prove our main theorems for fully observed LDS in the adversarial setting (Section 7), fully observed LDS in the stochastic setting (Section 8), and for partially observed LDS in the stochastic setting (Section 9), through establishing this structural condition.

## 2 Problem setting and algorithm

The problem of online state prediction for a LDS falls within the framework of online least squares. We first introduce the general problem of online least squares (Section 2.1), and then specialize to the prediction problem for a fully observed (Section 2.2) or partially observed (Section 2.3) LDS. Because the observations come from a sequential process, they have extra structure that we will
leverage to obtain better guarantees than for black-box online least squares. In Section 2.4, we describe the challenges associated with marginally stable systems.

2.1 The online least squares problem

In the problem of online least squares, at each time $t$ we are given $x_t \in \mathbb{R}^m$, and asked to predict $y_t \in \mathbb{R}^n$. We choose a matrix $A_t \in \mathbb{R}^{n \times m}$ and predict $\hat{y}_t = A_t x_t \in \mathbb{R}^n$. The desired output $y_t$ is then revealed and we suffer the squared loss $\| \hat{y}_t - y_t \|^2$. A natural goal in this setting is to predict as well as if we had known the best matrix in hindsight; hence, the performance metric is given by the regret with respect to $A$, defined by

$$ R_T(A) = \sum_{t=1}^{T} \| A_t x_t - y_t \|^2 - \sum_{t=1}^{T} \| A_t x_t - y_t \|^2. $$

Define the regret with respect to a given set $K \subseteq \mathbb{R}^{n \times m}$ by $R_T(K) = \sup_{A \in K} R_T(A)$. In general, we would like to achieve $R_T$ that is sublinear in $T$, or equivalently, average regret $\frac{R_T}{T}$ that converges to 0. In some cases, we can do better, and achieve regret $R_T$ that is polylogarithmic in $T$.

A natural algorithm for online least squares is to choose $A_t$ that minimizes the total squared prediction error for all the pairs $(x_s, y_s)$, $1 \leq s \leq t-1$ seen so far, plus a regularization term:

**Algorithm 1** Online Least Squares Regression

**Input:** Regularization parameter $\mu$.

for $t = 1$ to $T$ do
    Let $A_t = \text{argmin}_{A \in \mathbb{R}^{n \times m}} (\mu \| A \|^2_F + \sum_{t=1}^{T} \| A x_t - y_t \|^2)$. 
    Predict $\hat{y}_t := A_t x_t$ and observe cost $\| \hat{y}_t - y_t \|^2$.
end for

We state the standard regret bound for Algorithm 1.

**Theorem 2.1** (OLS regret bound; Thm. 11.7, [CL06]). In the online least squares setting, suppose that $\| x_t \| \leq M$ for all $t$. Then, Algorithm 1 incurs regret

$$ R_T(A) \leq \mu \| A \|^2_F + \max_{0 \leq t \leq T-1} \| y_t - A_t x_t \|^2 + \frac{m n \ln \left( 1 + \frac{T M^2}{n} \right)}{2}. $$

Thus, if there is a uniform bound on the prediction errors $\| y_t - A_t x_t \|$, online least squares achieves logarithmic regret. This follows immediately in the usual OLS setting, where $x_t, y_t,$ and $A_t$ are bounded. However, in the case where they can grow with time, as in marginally stable systems, a more sophisticated analysis will be necessary to get sublinear regret bounds.

2.2 Prediction in fully-observed linear dynamical systems

A special case of online least squares is state prediction in a time-invariant linear dynamical system (LDS), defined as follows. Given an initial state $x_0 \in \mathbb{R}^d$, matrices $A \in \mathbb{R}^{d \times d}$ and $B \in \mathbb{R}^{d \times m}$, inputs $u_0, \ldots, u_{T-1} \in \mathbb{R}^m$ and a sequence of perturbations $\xi_1, \ldots, \xi_T \in \mathbb{R}^d$, the LDS produces a time series of states $x_1, \ldots, x_T \in \mathbb{R}^d$ according to the following dynamics:

$$ x_t = Ax_{t-1} + B u_{t-1} + \xi_t, \quad 1 \leq t \leq T. \quad (1) $$
This setting generalizes the linear Gaussian model from control theory and time-series analysis, in which each $\xi_t$ is drawn i.i.d. from a Gaussian distribution. Aside from modeling disturbances, $\xi_t$ can also represent model uncertainty or misspecification.

In the prediction problem for LDS, we are asked to predict $x_{t+1}$ as a linear function of the current $x_t$ and the input $u_t$. We can treat this as an online least squares problem, by casting $(x_t, u_t)$ as the input at time $t$, and $x_{t+1}$ as the desired output. At each step, the learner produces $A_t$ and $B_t$ and predicts $\hat{x}_{t+1} = A_t x_t + B_t u_t$. Thus, we can adapt Algorithm 1 to this setting with the substitution $x_t \leftarrow$ maps from $x_t u_t$, $y_t \leftarrow$ maps from $x_{t+1}$, $A \leftarrow$ maps from $(A, B)$, $(n, m) \leftarrow (d, d + m)$, and obtain Algorithm 2.

Translated to this setting, the goal of regret minimization becomes that of predicting as accurately as if one had known the system’s underlying matrices $A$ and $B$.  

Algorithm 2 Online Least Squares Regression (LDS setting)
1: Input: Regularization parameter $\mu$.
2: for $t = 0, \ldots, T - 1$ do
3: Estimate dynamics as $(A_t, B_t) := \arg\min_{(A, B)} \left( \mu \|(A, B)\|_F^2 + \sum_{s=0}^{t-1} \|A x_s + B u_s - x_{s+1}\|^2 \right)$.
4: Predict state: $\hat{x}_{t+1} := A_t x_t + B_t u_t$ and suffer loss $\|\hat{x}_{t+1} - x_{t+1}\|^2$.
5: end for

Note that in the stochastic setting, when the covariance of the noise is lower-bounded in each direction, OLS gives a consistent estimator for $A$ and $B$; convergence rates for recovery are analyzed in [SR19; Sim+18]. However, in the adversarial setting, recovery of $A$ is an ill-posed problem. The perturbations can be biased or rank-deficient, causing the recovery problem to be underdetermined in general, and the optimal $A$ may change as time.

2.3 Prediction in partially-observed linear dynamical systems

A partially-observed linear dynamical system is defined by
\[
\begin{align*}
x_t & = A x_{t-1} + B u_{t-1} + \xi_t \quad (2) \\
y_t & = C h_t + \eta_t, \quad (3)
\end{align*}
\]
where $u_t \in \mathbb{R}^m$ are inputs, $x_t \in \mathbb{R}^d$ are hidden states, $y_t \in \mathbb{R}^n$ are observations, $A \in \mathbb{R}^{d \times d}$, $B \in \mathbb{R}^{d \times m}$ and $C \in \mathbb{R}^{n \times d}$ are matrices, and $\xi_t \in \mathbb{R}^d$ and $\eta_t \in \mathbb{R}^n$ are perturbations. We consider the stochastic setting, so that $\xi_t$ and $\eta_t$ are independent zero-mean noise terms. Crucially, only the $y_t$, and not the $x_t$, are observed.

For prediction in this setting, we use Algorithm 3 regressing with the previous $\ell$ observations and inputs, so we slightly modify the definition of the regret in (117) to start accruing from $t = \ell + 1$:
\[
R_T(A, B, C) = \sum_{t=\ell+1}^{T} \|\hat{y}_t - y_t\|^2 - \sum_{t=\ell+1}^{T} \|\hat{y}_{KF,t} - y_t\|^2,
\]
where $\hat{y}_{KF,t}$ is the prediction of the steady-state Kalman filter for the system $(A, B, C)$; see Appendix 3 for a review and formal definitions. Note that we will learn the system in an improper
manner: that is, we will predict \( \hat{y}_t \) using a general autoregressive filter, rather than the Kalman filter of some system.

**Algorithm 3**

Online Least Squares Autoregression for LDS

1: **Input:** Regularization parameter \( \mu \), rollout length \( \ell \).

2: for \( t = 0 \) to \( T - 1 \) do

3: Estimate the autoregressive filter:

\[
(F_t, G_t) := \arg\min_{F \in \mathbb{R}^{n \times \ell m}, G \in \mathbb{R}^{n \times \ell n}} \left( \mu \| (F, G) \|_F^2 + \sum_{s=\ell-1}^{t-1} \| F u_{s:s-\ell+1} + G y_{s:s-\ell+1} - y_{s+1} \|_2^2 \right).
\]

4: Predict state: \( \hat{y}_{t+1} := F_t u_{t:t-\ell+1} + G_t y_{t:t-\ell+1} \) and suffer cost \( \| \hat{y}_{t+1} - y_{t+1} \|_2^2 \).

5: end for

2.4 Marginally stable systems

In this work, we are interested in prediction in marginally stable systems. In both the fully-observed and partially-observed cases, the spectral radius \( \rho(A) \) of the system is defined to be the magnitude of the largest eigenvalue of the transition matrix \( A \), as in Equations 1 and 2. An LDS is marginally stable if \( \rho(A) = 1 \).

As opposed to strictly stable systems (ones for which \( \rho(A) < 1 \)), these systems model phenomena where the state does not reset itself over time, often representing physical systems which experience little or no dissipation. As discussed in Section 3, their capacity to represent long-term dependences presents algorithmic and statistical challenges. An inverse spectral gap factor \( \frac{1}{1-\rho(A)} \) appears in the computational and statistical guarantees for many learning algorithms in these settings (see, e.g. [HMR16]), as a finite-impulse truncation length or mixing time, rendering those results inapplicable.

Among marginally stable systems, the hardest cases are those with large Jordan blocks corresponding to large eigenvalues. Defining the Jordan matrix

\[
J_{\lambda,r} := \begin{pmatrix}
\lambda & 1 & 0 & \cdots & 0 \\
0 & \lambda & 1 & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots & \vdots \\
0 & 0 & 0 & \lambda & 1 \\
0 & 0 & 0 & 0 & \lambda
\end{pmatrix} \in \mathbb{R}^{r \times r},
\]

we see that for marginally stable systems, \( \| J_{\lambda,r}^t \|_2 \) can grow polynomially in \( t \). These occur naturally in physical systems as discrete-time integrators of \( r \)-th degree ordinary differential equations. The primary challenge we overcome in this work is to show the sublinear regret of least squares, even when the state grows polynomially. As is also the case in our work, recent advances in parameter recovery of marginally stable systems [Sim+18; SR19] exhibit exponential dependences on the largest Jordan block order \( r \).
3 Related work

Linear dynamical systems have been studied in a number of disciplines, including control theory [GH96; Kal63], astronomy [CGG92], econometrics [HD94], biology [Sau94], and chemical kinetics. They capture many popular models in statistics and machine learning [GH96]. We first describe the results on parameter estimation and prediction in fully observed systems, and then describe results more broadly applicable to partially observed systems. Unless noted otherwise, the results hold under the assumption that the noise is i.i.d.; some results also require that it be Gaussian.

Fully-observed LDS. [Dea+17] show that when given independent rollouts of a LDS, the least-squares estimator of the parameters is sample-efficient. Using this, they obtain sub-optimality bounds for control. [Sim+18] consider the more challenging case when only a single trajectory is given, and show that the least-squares estimator is still efficient, despite correlations across timesteps. Their results hold for marginally stable systems. Improving over [Sim+18] and [FTM18], [SR19] offer bounds applicable even to explosive systems, with the restriction that explosive eigenvalues have unit geometric multiplicity. In order to obtain results for parameter recovery, all these results assume that the covariance of the noise is lower bounded. Because we are concerned with prediction, this requirement will not be necessary for our results.

Partially-observed LDS. For a system with known parameters, the celebrated Kalman filter [Kal60] provides an analytic solution for the posterior distribution of the latent states and future observations given a series of observations. When the underlying parameters are unknown, the Expectation Maximization (EM) algorithm can be used to learn them [GH96]. However, due to nonconvexity of the problem, EM is only guaranteed to converge to local optima. In the absence of process noise $\xi_t$, [HMR16] show that gradient descent on the maximum likelihood objective converges to the global minimum; however, they require the roots of the associated characteristic polynomial to be well-separated and the system to be strictly stable.

Subspace identification methods circumvent the nonconvexity of maximum likelihood estimation. For strictly stable systems, [OO18] demonstrate that the Ho-Kalman algorithm learns the Markov parameters of the underlying system at an optimal rate (in $T$), and identifies the parameters approximately up to an equivalent realization (at a rate of $T^{-1/4}$) under further assumptions of observability\footnote{This notion of “observable” is not to be confused with the system being partially observable.} and controllability. [SBR19] showed that a prefiltered variant of least-squares offers stronger guarantees that apply even to marginally stable systems and systems with adversarial noise. For strictly stable stochastic systems, [SRD19] improve upon previous works to give an optimal rate for parameter identification. We note that these works require the control inputs, and often the noise, to be Gaussian. This may not hold when the control inputs are exogenous (not under user control). In contrast, our results can handle arbitrary (bounded) control inputs.

In a notable departure from this trend, [TP19] demonstrate optimal recovery of system parameters in the absence of control inputs for marginally stable systems. Under similar conditions, [TMP19] prove the first result that integrates former system identification results with a perturbation analysis for the Kalman filter to obtain error bounds on prediction. These results only apply to stochastic systems subject to persistent excitation, which our stochastic-case result does not require.
Prediction via improper learning. For strictly stable partially observed systems without process noise, it is sufficient to learn a finite impulse response (FIR) filter on the inputs, as observed by e.g. [HMR16]. [Tu+17] give near-optimal sample complexity bounds for learning a FIR filter under design inputs. [HSZ17; Haz+18; Aro+18] instead use spectral filtering on the inputs to achieve regret bounds that apply in the presence of adversarial dynamics and marginally stable systems, much like the present work. However, in the presence of process noise, the regret compared to the optimal filter can grow linearly. This is an inherent limitation of any FIR-based approach; see [LZ19] for a discussion.

[Koz+19] note if the LDS is observable, the associated Kalman filter is strictly stable, and hence can be arbitrarily well-approximated by an autoregressive (AR) model. [Ana+13] give algorithms for prediction in ARMA models with adversarial noise. However, their results hold under conditions more stringent than even strict stability. [Koz+19] shows that online gradient descent on the AR model gives regret bounds scaling with the size of the observations. As discussed in Section 2.4 In the marginally stable case, this could be polynomial in the time $T$. [LZ19] give guarantees for learning an autoregressive filter in a stricter notion of $H_{\infty}$ norm, but require the system to be strictly stable.

Online learning. We use tools from online learning (see [Haz+16; Sha+12; CL06] for a survey). The standard regret bounds for online least-squares scale with an upper bound on the maximum instantaneous loss, through the gradient norm or the exp-concavity factor [Zin03; HAK07]. Our core argument shows that this quantity is sublinear in $T$ in the LDS setting. This cannot be true for online least-squares for arbitrary polynomially growing $x_t$, so black-box results cannot apply; see Appendix A. We note the similarity of our approach to [RS12; RS13] where the authors show that approximate knowledge of cost functions or gradients revealed one step in advance can give “beyond worst-case” regret bounds.

4 Our results

4.1 Fully-observed LDS

For prediction in a fully-observed LDS, we show that we can achieve sublinear regret in the adversarial setting and polylogarithmic regret in the stochastic setting.

We will make the following assumptions for both theorems:

Assumption 4.1. The linear dynamical system

$$x_t = Ax_{t-1} + Bu_{t-1} + \xi_t$$

satisfies the following:

- The initial state is bounded: $\|x_0\| \leq C_0$.
- The inputs are bounded: $\|u_t\| \leq C_u$.
- The perturbations are bounded: $\|\xi_t\| \leq C_\xi$ for $1 \leq t \leq T$.
- $\|A\|_F \leq R$, $\rho(A) \leq 1$, and $A$ can be written in Jordan form as $A = SJ S^{-1}$ where $J$ has Jordan blocks of size $\leq r$ and $\|S\|_2 \|S^{-1}\|_2 \leq C_A$. 

• $B$ satisfies $\|B\|_2 \leq C_B$.

We will let $C_{sys} = \max\{C_0, C_A, C_B, C_ξ\}$.

We note that the bound on the perturbations $C_ξ$ is necessary. This prevents, for example, the pathological case when the system switches between two very different linear dynamical systems $x_t = x_{t-1} + u_{t-1}$ and $x_t = -(x_{t-1} + u_{t-1})$ and linear regret is unavoidable. We also note that $\|S\|_2 \|S^{-1}\|_2$ (the condition number of $S$) is a standard quantity that often appears in learning guarantees.

Our main theorem in the adversarial setting is the following; see the appendix more precise dependences on individual constants.

**Theorem 4.2** (Sublinear regret in the adversarial setting). Suppose Assumption 4.7 holds. Then, there is an explicit choice of regularizer $\mu$ such that Algorithm 7 achieves regret

$$R_T(A, B) \leq T^{\frac{2r+1}{r+2}} \text{poly}(C_{sys}, R, (d+m), (\ln T), (\ln C_{sys}))$$

$$+ T^{\frac{1}{r+2}} \text{poly}(C_{sys}, R, (d+m)^r, (\ln T)^r, (\ln C_{sys})^r).$$

If $C_{sys} = O(1)$ and $\|A\|_F = O(\sqrt{md})$,

$$R_T(A, B) = O\left(m^3d^3(m+d)r^2 \cdot T^{\frac{2r+1}{r+2}} \ln^3 T\right)$$

as $T \to \infty$. The dependence of $\mu$ on $T$ is $T^{\frac{2r+1}{r+2}}$.

**Remark.** This is a pessimistic bound. The worst case is when the eigenvalues of the large Jordan blocks are close to 1. If $\|A^k\| \leq C^r k^r$, then we can replace the dependence on $r$ with $r'$, and instead suffer a poly($C'$) dependence.

In the case where $A$ is diagonalizable, Theorem 4.2 implies $\tilde{O}(T^{3/4})$ regret:

**Corollary 4.3.** Suppose Assumption 4.7 holds, and further suppose $A$ is diagonalizable. There is an explicit choice of regularizer $\mu$ such that Algorithm 2 achieves regret

$$R_T(A, B) \leq T^{3/4} \text{poly}(C_{sys}, R, d, m, \ln T).$$

When $C_{sys} = O(1)$ and $R = O(\sqrt{mn})$, we have $R_T(A, B) = O(m^{5/2}d^2(m+d)T^{3/4} \ln^3 T)$ as $T \to \infty$. The dependence of $\mu$ on $T$ is $T^{3/4}$.

Our main theorem in the stochastic setting is the following.

**Theorem 4.4** (Polylogarithmic regret in stochastic setting). Suppose Assumption 4.7 holds, and further that $ξ_t$ is a random variable satisfying $\mathbb{E}[ξ_t|ξ_{t-1}, \ldots, ξ_1] = 0$. Then with probability at least $1 - δ$, Algorithm 2 with $\mu = 1$ achieves regret

$$R_T(A, B) \leq \text{poly}(C_{sys}, R, d^r, (\ln T)^r, (\ln C_{sys})^r, (\ln (1/δ))).$$

Note that there is no requirement that the noise be i.i.d., nor that their covariance is greater than some multiple of the identity. At the expense of a $\ln T$ factor, the theorem can be applied to subgaussian random variables, by first conditioning on the event that $\|ξ_t\| \leq C_ξ$ for all $1 \leq t \leq T$.
4.2 Partially-observed LDS

Our assumptions in the partially observed setting are the following. We will assume that the noise is i.i.d. Gaussian; this is the analogue of the linear-quadratic estimation (LQE) setting where we only care about predicting the observation.

**Assumption 4.5.** The partially-observed LDS defined by (2) – (3) satisfies the following:

- The initial state has steady-state covariance: \( x_0 \sim N(x^-_0, \Sigma_0) \) with \( \|x^-_0\| \leq C_0 \).
- The inputs are bounded: \( \|u_t\| \leq C_u \).
- The perturbations are Gaussian: \( \xi_t \sim N(0, \Sigma_x) \) and \( \eta_t \sim N(0, \Sigma_y) \).
- \( \|A\|_F \leq R \), \( \rho(A) \leq 1 \), and \( A \) can be written in Jordan form as \( A = SJS^{-1} \) where \( J \) has Jordan blocks of size \( \leq r \) and \( \|S\|_2 \|S^{-1}\|_2 \leq C_A \).
- \( B \) and \( C \) satisfy \( \|B\|_2 \leq C_B \) and \( \|C\|_2 \leq C_C \).

We will let \( C_{\text{sys}} = \max\{C_0, C_A, C_B, C_C, \|\Sigma_0\|, \|\Sigma_x\|, \|\Sigma_y\|\} \).

For simplicity, our result assumes that \( x_0 \) has steady-state covariance. If this is not the case, then one would need quantitative bounds on how quickly the time-varying Kalman filter converges to the steady-state Kalman filter, to bound the additional regret incurred by using a fixed filter.

The theorem also depends on the sufficient length \( R(\varepsilon) \) of the Kalman filter, which is roughly the length at which we can truncate the unrolled filter to incur an error of at most \( \varepsilon \); see Definition E.2 for a precise account. If the filter decays exponentially, then \( R(\varepsilon) = O(\ln(1/\varepsilon)) \). It remains an interesting problem to handle the case where the filter is also marginally stable.

**Theorem 4.6 (Polylogarithmic regret for LQE).** Assume Assumption 4.5. Suppose the corresponding Kalman filter is given by \( A_{\text{KF}}, B_{\text{KF}}, \text{ and } C_{\text{KF}} \). Let \( R(\cdot) \) denote the sufficient length of the Kalman filter system, and choose \( \ell = R(\delta \left[ T^r C_C C_A \left( C_B C_u + 10 \|\Sigma_x\| \sqrt{d \ln \left( \frac{T}{\delta} \right)} \right) \right]^{-1}) \). Let \( (F_t, G_t) = C_{\text{KF}} A_{\text{KF}}^t B_{\text{KF}} \) be the unrolled Kalman filter, and suppose \( \sum_{t=0}^{\ell-1} \|F_t\|^2 + \|G_t\|^2 \leq R^2 \).

Then with probability \( 1 - \delta \), Algorithm 3 with \( \mu = 1 \) achieves regret

\[
R_T(A, B, C) \leq \text{poly}(\ell, C_{\text{sys}}, R, (d + m)^r, (\ln T)^r, (\ln C)^r, \ln(1/\delta)).
\]  

**5 Outlines of main proofs**

In this section, we explain the key ideas behind our results, using a fully observable LDS with adversarial noise as an example. For simplicity, we sketch the proof in the case that the matrix \( A \) is diagonalizable, matrix \( B \) is zero, and \( \|\xi_s\|_2 = O(1) \), which already captures the core difficulty of the problem. In the proof sketch, we assume that all relevant parameters for the LDS are \( O(1) \). Full proofs are in Sections B–E.
5.1 Regret bounds for online least squares with large inputs

Our starting point is the regret bound for online least squares, Theorem 2.1, which depends on the maximum prediction error \( \max_{0 \leq t \leq T-1} \| y_t - A_t x_t \|_2 \). To obtain sublinear regret using this bound, we must show that the maximum prediction error is \( o(T/\log T) \). We show in Theorem B.2 that this holds as long as the following structural condition (formally defined in Definition B.1) on the regressor sequence holds:

Definition 5.1 (Anomaly-free sequences; informal). A sequence \( (x_t)_{t < T} \) is **anomaly-free** if whenever the projection of any \( x_t \) onto a unit vector \( w \) is large, then there must have been \( \Omega(\| w^T x_t \|) \) indices \( s < t \) for which the projection of \( x_s \) to \( w \) has norm at least \( \Omega(\| w^T x_t \|) \).

Intuitively, the inputs are anomaly-free if no input \( x_t \) is large in a direction where we have not already seen many inputs. Note this does not hold in the general case of polynomially-bounded \( x_t \); see the counterexample in Appendix A. To prove Theorem B.2, we first express \( A_t x_t - y_t \) in terms of the preceding states and errors \( \{ x_s, \xi_s \}_{s < t} \) (Lemma B.3). Next, we show this expression is bounded in the 1-dimensional case (Lemma B.4). Finally, we reduce the general \( d \)-dimensional case to the 1-dimensional case by diagonalizing the sample covariance matrix \( \sum_{t=0}^{t-1} x_s x_s^T \). In the reduction, we project onto the eigendirections; this is why we want there to be many large inputs when projected to any direction \( w \).

Note that Theorem B.2 is stated more generally, allowing \( \Omega(\| w^T x_t \|^\alpha) \) indices where \( |w^T x_t| \) is large. This allows superlinear growth in the \( x_t \), and hence can be applied to dynamical systems with matrices having Jordan blocks.

5.2 Proving LDS states are anomaly-free

Our main result (Theorem 4.2) follows by verifying that LDS states are anomaly-free. The main idea is that the evolution of the LDS ensures that \( x_t \) is always approximately a linear combination of past states with small coefficients. More precisely, we need \( x_t = (\sum_{s=0}^{t-1} a_s x_s) + v \) with small \( \sum_{s=0}^{t-1} |a_s| \) and \( \|v\|_2 \) (Lemma C.5). Once we have this, projecting onto \( w \) gives \( w^T x_t = (\sum_{s=0}^{t-1} a_s w^T x_s) + w^T v \), showing that one of the projections \( |w^T x_s| \) is large. To obtain many indices \( s \) for which this is large, we apply the same argument to the \( k \)-step dynamical systems defined by \( A^2, A^3 \), and so forth, keeping track of how many times an index can be overcounted. This shows the states are anomaly-free and finishes the proof of Theorem 4.2.

We provide two approaches to decompose \( x_t \) into previous states as needed. The simpler approach provides coefficients of size \( \exp(d) \), while a more involved approach provides \( \text{poly}(d) \) sized coefficients. In order to have a \( \text{poly}(d) \) dependence in the final regret bound, the latter approach is necessary.

5.3 \( \exp(d) \)-sized coefficients using the Cayley-Hamilton theorem

To show that \( x_t \) is always a linear combination of previous states with small coefficients, a first idea is to use the Cayley-Hamilton theorem. In the noiseless case, the theorem implies that the \( x_t \) satisfy a recurrence \( x_t = \sum_{i=1}^{d} a_i x_{t-i} \), where \( a_i \) are the coefficients of the characteristic polynomial of \( A \). Adding the noise back, we may get an error term \( v \) of size \( \sum_{i=1}^{d} |a_i| \) by inspecting how the noise propagates through this recurrence. Even though \( \sum_{i=0}^{d} |a_i| \) can be as large as \( 2^d \), this suffices to get a bound that is sublinear in \( T \) while exponential in \( d \). For ease of reading, we first present this weaker result in Lemma C.2 in Section C.1.
5.4 poly(d)-sized coefficients via volume doubling

As an alternative, we now present a novel volume-doubling argument leading to a recurrence with only poly(d) coefficient size, which may be of independent interest. For the ease of presentation, we introduce some notation below:

- **ℓ₁-span of S.** \( \Delta(S) := \{ \sum_{u \in S} a_u u : a_u \in \mathbb{R}, \sum_{u \in S} |a_u| \leq 1 \} \). For short, we denote \( \Delta_t := \Delta(\{x_s\}_{s=0}^t) \).
- **Norm with respect to \( \Delta(S) \).** \( \|x\|_{\Delta(S)} := \min_{a_s, v} \sum_{s=0}^t |a_s| + \|v\|_2 \) s.t. \( x = (\sum_{s=0}^t a_s x_s) + v \) for \( x_s \in S \).
- **Set of “outlier” indices.** \( I_t := \{ 0 \leq s \leq t : \|x_s\|_{\Delta_{s-1}} \geq 2 \ln 2 d \} \).

Now, our goal is summarized as bounding \( \|x_t\|_{\Delta_{t-1}} \). To this end, we first prove a upper bound the size of \( I_t \) using a general potential-based argument, and then relate it to the norm \( \|x_t\|_{\Delta_{t-1}} \) by unrolling the dynamics appropriately.

**Bounding the number of outliers.** We have to show that \( |I_t| \) is at most polynomial in \( d \) and logarithmic in \( t \). We prove a general lemma that if \( \|x\|_{\Delta(S)} \) is large enough (\( \|x\|_{\Delta(S)} \geq 2 \ln 2 d \)), then adding \( x \) to the \( S \) increases its volume significantly: \( \text{Vol}(\Delta(S \cup \{x\})) \geq 2 \ln(\Delta(S)) \) (Lemma C.7). Applied to our situation, this shows that if \( \|x_t\|_{\Delta_{t-1}} \geq 2 \ln 2 d \), then \( \text{Vol}(\Delta_t) \geq 2 \text{Vol}(\Delta_{t-1}) \). The total volume is bounded by \( (\max_{1 \leq s \leq t} \|x_s\|)^d \), so the number of outliers at or before time \( t \) is bounded by \( \log_2 [(\max_{1 \leq s \leq t} \|x_s\|)^d] \), which is polynomial in \( d \) and logarithmic in \( t \) (Lemma C.8).

**Bounding \( \sum_{s=0}^{t-1} |a_s| \) and \( \|v\|_2 \).** We obtain an inequality showing that \( \|x_t\|_{\Delta_{t-1}} \) is not much larger than \( \|x_{t-k}\|_{\Delta_{t-k-1}} \) for small delays \( k \). To see this, note that \( x_t \) is generated from \( x_{t-k} \) by evolving the LDS \( k \) times, keeping track of noise. The contribution from the noise here is at most \( \text{poly}(k) \).

Now, it suffices to find a small \( k \) such that \( \|x_{t-k}\|_{\Delta_{t-k-1}} \) is small, or in other words \( t - k \) is not an outlier. Because the number of outliers is \( O(d \log t) \), we can choose \( k = O(d \log T) \), and we conclude \( \|x_t\|_{\Delta_{t-1}} \) is at most \( \text{poly}(d \log t) \). This argument is formalized in the proof of Lemma C.3.

**Controlling overcounting using prime index gaps.** One technicality is that we have to apply the same argument to the dynamical systems \( x_t \approx A^t x_{t-p} \) for different values of \( p \). For each value of \( p \), we get an index \( t - pk \) such that \( w^\top x_{t-pk} \) is large. To make sure we obtain enough indices this way, in the proof of Lemma C.11 we only take \( p \) to be prime, and we use a lower bound on primorials \( \prod_{p \leq x} p \) to show that we can collect enough distinct indices.

5.5 Stochastic cases

Finally, we provide a brief comment on how to prove Theorems 4.4 and 4.6. In the fully-observed setting, we can use a martingale argument, rather than the structural result, to obtain \( \text{poly}(\log(T)) \) regret. To do this, we show that with high probability, \( \max_{0 \leq t \leq T-1} \|A_t v_t - v_{t+1}\| \) is bounded by \( \text{poly}(\log(T)) \) (Lemma D.1). Let \( A_t \) be the matrix predicted by online least squares with regularization parameter \( \mu \). By Lemma B.3, \( A_t x_t - x_{t+1} = \sum_{s=0}^{t-1} \xi_{s+1} v_{s+1} \Sigma_{s+1} ^{-1} v_{s} - \mu A \Sigma_{s} ^{-1} x_t - \xi_{t+1} \). The main term we need to bound is the first one. Let \( b_s = v_s \Sigma_{s} ^{-1} v_t \). Pretending for a moment that \( b_s \) is \( \mathcal{F}_s = \sigma(\xi_1, \ldots, \xi_s) \)-valued,
by Azuma’s inequality it suffices to bound the variation $\sum_{s=0}^{t-1} b_s^2$. We have already shown that $v_t = \sum_{s=0}^{t-1} a_s v_s$ with $\sum_{s=0}^{t-1} a_s^2 \leq \left( \sum_{s=0}^{t-1} |a_s| \right)^2 \leq O(1)$, so we can bound the variation $\sum_{s=0}^{t-1} b_s^2$ in terms of $\sum_{s=0}^{t-1} \left\| s^{-\frac{1}{2}} v_s \right\|^2$. By definition $\Sigma_t = \mu I + \sum_{s=0}^{t-1} v_s v_s^\top$, so $\sum_{s=0}^{t-1} \left\| s^{-\frac{1}{2}} v_s \right\|^2 \leq d$.

However, we can’t apply Azuma’s inequality directly, since $b_s$ depends on $v_t$, and thus is not $\mathcal{F}_s$-valued. However, the dependence on non-$\mathcal{F}_s$-valued random variables is only through $z_t = \Sigma_t^{-1} v_t$, which does not depend on $s$, so we can use Azuma’s inequality on an $\varepsilon$-net of possible values for $z = \Sigma_t^{-1} v_t$. More precisely, note that $z_t$ has the property that $\sum_{s=0}^{t-1} (v_s^\top z_t)^2$ is small, so it suffices to bound $\sum_{s=0}^{t-1} \xi_{s+1}(v_s^\top z)$ for an $\varepsilon$-net of $z$ such that $\sum_{s=0}^{t-1} (v_s^\top z)^2$ is small. These $z$’s live in a $d$-dimensional space, so we only incur factors of $d$.

For the partially-observed setting, we reduce to Theorem 4.4 by lifting the state: we choose $\ell = \sum_{s=0}^{t-1} a_s v_s$ with $\sum_{s=0}^{t-1} a_s^2 \leq \left( \sum_{s=0}^{t-1} |a_s| \right)^2 \leq O(1)$, so we can use Azuma’s inequality on an $\varepsilon$-net of possible values for $z = \Sigma_t^{-1} v_t$. More precisely, note that $z_t$ has the property that $\sum_{s=0}^{t-1} (v_s^\top z_t)^2$ is small, so it suffices to bound $\sum_{s=0}^{t-1} \xi_{s+1}(v_s^\top z)$ for an $\varepsilon$-net of $z$ such that $\sum_{s=0}^{t-1} (v_s^\top z)^2$ is small. These $z$’s live in a $d$-dimensional space, so we only incur factors of $d$.

For the partially-observed setting, we reduce to Theorem 4.4 by lifting the state: we choose $\ell = \sum_{s=0}^{t-1} a_s v_s$ with $\sum_{s=0}^{t-1} a_s^2 \leq \left( \sum_{s=0}^{t-1} |a_s| \right)^2 \leq O(1)$, so we can use Azuma’s inequality on an $\varepsilon$-net of possible values for $z = \Sigma_t^{-1} v_t$. More precisely, note that $z_t$ has the property that $\sum_{s=0}^{t-1} (v_s^\top z_t)^2$ is small, so it suffices to bound $\sum_{s=0}^{t-1} \xi_{s+1}(v_s^\top z)$ for an $\varepsilon$-net of $z$ such that $\sum_{s=0}^{t-1} (v_s^\top z)^2$ is small. These $z$’s live in a $d$-dimensional space, so we only incur factors of $d$.

For the partially-observed setting, we reduce to Theorem 4.4 by lifting the state: we choose $\ell = \sum_{s=0}^{t-1} a_s v_s$ with $\sum_{s=0}^{t-1} a_s^2 \leq \left( \sum_{s=0}^{t-1} |a_s| \right)^2 \leq O(1)$, so we can use Azuma’s inequality on an $\varepsilon$-net of possible values for $z = \Sigma_t^{-1} v_t$. More precisely, note that $z_t$ has the property that $\sum_{s=0}^{t-1} (v_s^\top z_t)^2$ is small, so it suffices to bound $\sum_{s=0}^{t-1} \xi_{s+1}(v_s^\top z)$ for an $\varepsilon$-net of $z$ such that $\sum_{s=0}^{t-1} (v_s^\top z)^2$ is small. These $z$’s live in a $d$-dimensional space, so we only incur factors of $d$.

For the partially-observed setting, we reduce to Theorem 4.4 by lifting the state: we choose $\ell = \sum_{s=0}^{t-1} a_s v_s$ with $\sum_{s=0}^{t-1} a_s^2 \leq \left( \sum_{s=0}^{t-1} |a_s| \right)^2 \leq O(1)$, so we can use Azuma’s inequality on an $\varepsilon$-net of possible values for $z = \Sigma_t^{-1} v_t$. More precisely, note that $z_t$ has the property that $\sum_{s=0}^{t-1} (v_s^\top z_t)^2$ is small, so it suffices to bound $\sum_{s=0}^{t-1} \xi_{s+1}(v_s^\top z)$ for an $\varepsilon$-net of $z$ such that $\sum_{s=0}^{t-1} (v_s^\top z)^2$ is small. These $z$’s live in a $d$-dimensional space, so we only incur factors of $d$.

For the partially-observed setting, we reduce to Theorem 4.4 by lifting the state: we choose $\ell = \sum_{s=0}^{t-1} a_s v_s$ with $\sum_{s=0}^{t-1} a_s^2 \leq \left( \sum_{s=0}^{t-1} |a_s| \right)^2 \leq O(1)$, so we can use Azuma’s inequality on an $\varepsilon$-net of possible values for $z = \Sigma_t^{-1} v_t$. More precisely, note that $z_t$ has the property that $\sum_{s=0}^{t-1} (v_s^\top z_t)^2$ is small, so it suffices to bound $\sum_{s=0}^{t-1} \xi_{s+1}(v_s^\top z)$ for an $\varepsilon$-net of $z$ such that $\sum_{s=0}^{t-1} (v_s^\top z)^2$ is small. These $z$’s live in a $d$-dimensional space, so we only incur factors of $d$.

For the partially-observed setting, we reduce to Theorem 4.4 by lifting the state: we choose $\ell = \sum_{s=0}^{t-1} a_s v_s$ with $\sum_{s=0}^{t-1} a_s^2 \leq \left( \sum_{s=0}^{t-1} |a_s| \right)^2 \leq O(1)$, so we can use Azuma’s inequality on an $\varepsilon$-net of possible values for $z = \Sigma_t^{-1} v_t$. More precisely, note that $z_t$ has the property that $\sum_{s=0}^{t-1} (v_s^\top z_t)^2$ is small, so it suffices to bound $\sum_{s=0}^{t-1} \xi_{s+1}(v_s^\top z)$ for an $\varepsilon$-net of $z$ such that $\sum_{s=0}^{t-1} (v_s^\top z)^2$ is small. These $z$’s live in a $d$-dimensional space, so we only incur factors of $d$.

For the partially-observed setting, we reduce to Theorem 4.4 by lifting the state: we choose $\ell = \sum_{s=0}^{t-1} a_s v_s$ with $\sum_{s=0}^{t-1} a_s^2 \leq \left( \sum_{s=0}^{t-1} |a_s| \right)^2 \leq O(1)$, so we can use Azuma’s inequality on an $\varepsilon$-net of possible values for $z = \Sigma_t^{-1} v_t$. More precisely, note that $z_t$ has the property that $\sum_{s=0}^{t-1} (v_s^\top z_t)^2$ is small, so it suffices to bound $\sum_{s=0}^{t-1} \xi_{s+1}(v_s^\top z)$ for an $\varepsilon$-net of $z$ such that $\sum_{s=0}^{t-1} (v_s^\top z)^2$ is small. These $z$’s live in a $d$-dimensional space, so we only incur factors of $d$.

6 Conclusion

We have shown that online least-squares, with a carefully chosen regularization and a refined analysis, has a sublinear regret guarantee in marginally stable linear dynamical systems, even in the most difficult cases when the state can grow polynomially. In the stochastic setting, adopting the same view of low-regret prediction as opposed to parameter recovery, we have shown logarithmic regret bounds and bypassed usual isotropic noise assumptions. Several fundamental questions come to mind:

1. Is the $T^{\frac{2r+1}{2r+2}}$ rate optimal? Even in the diagonalizable ($r = 1$) case, this is unresolved.

2. Is there a simpler way to get poly($d$) coefficients? The number-theoretic lemma required by Lemma C.11 to control overcounting is somewhat delicate, and we may have overlooked an elementary proof.

3. What is the rate for partially observed LDS when the noise is not Gaussian? We stated Theorem 4.6 for Gaussian noise only, but a similar result will hold as long as at steady state, $\mathbb{E}[y_t | \mathcal{F}_{t-1}]$ is given by a linear function of $y_{t-1:0}$, $u_{t-1:0}$, and the estimated state $x_0^-$. This is required in order for the random variable $y_t | \mathcal{F}_{t-1}$ to be a linear function of past observations and inputs, plus a random variable $\xi_t$ with zero mean. In general, if the noise $\xi_t$ is not Gaussian, then $\zeta_t$ is not zero-mean (even if $\xi_t$ is zero-mean). We use the same machinery as in the proof of Theorem 4.3 to conclude Theorem 4.6 so our proof strategy cannot handle arbitrary zero-mean noise $\xi_t$.

For non-Gaussian zero-mean noise $\xi_t$, we can instead treat the $\zeta_t$ as adversarial noise, and use the machinery behind Theorem 4.2 to obtain a $T^{\frac{2r+1}{2r+2}}$ regret bound. It is an interesting question whether we can obtain polylogarithmic regret with respect to the best linear filter in this case.

We leave these for future work.

A Impossibility of sublinear regret without the LDS

For sake of completeness, we include a simple one-dimensional counterexample showing the insufficiency of black-box regret bounds for online least-squares when it is only assumed that an upper bound for the regressors grows with time. Even without adversarial perturbations, this information-theoretic lower bound shows that we require a refined notion of gradual growth of regressors $x_t$, as in the structural results of Section 5.2 to achieve sublinear regret.

**Proposition A.1.** There is a joint distribution over $a \in [-1, 1]$ and length-$T$ sequences $x_t, y_t \in \mathbb{R}$, for which $y_t = ax_t$ and $|x_t| \leq t$, but any online algorithm incurs at least $T^2$ expected regret.

**Proof.** We construct this distribution, choosing $a = \pm 1$ with equal probability. We choose $x_t = y_t = 0$ for all $1 \leq t \leq T - 1$, then choose $x_T = T$, so that $y_T = ax_T$. In this example, at time $T$, all previous feedback $(x_t, y_t)$ is independent of $a$, so the best prediction at time $T$ is $\hat{y}_T = 0$, which suffers expected least-squares loss $T^2$. \bbox

B Anomaly-free inputs imply sublinear OLS regret

We begin by defining a structural condition on OLS inputs, whereby if any time $x_t$ is large in a direction then many previous $x_s$'s are also large in that direction.

**Definition B.1** (Anomaly-free sequences). A sequence $(x_t)$ is $(c, c_1, c_2, \alpha)$-anomaly-free if for any $t$ and any unit vector $w \in \mathbb{R}^d$, if $|w^\top x_t| = M > c$, there exist at least $c_1M^\alpha$ indices $s < t$ such that $|w^\top x_s| \geq c_2M$.

We show that when every $y_t$ is obtained from anomaly-free $x_t$ from a fixed linear transformation, plus a bounded perturbation, then OLS attains sublinear regret.

**Theorem B.2.** For constants $C_\xi, c, c_1, c_2, \alpha \in (0, 1)$, $c_1 \leq \frac{1}{2}$, $c \geq \frac{1}{c_1}$, suppose an online least-squares problem satisfies the following conditions:

1. There exists $A^* \in \mathbb{R}^{n \times m}$ such that for all $t$, $y_t = A^*x_t + \xi_t$ with $\|\xi_t\| \leq C_\xi$.
2. The input vectors are bounded: $\|x_t\| \leq B$.
3. $(x_s)_{s < t}$ is $(c, c_1, c_2, \alpha)$-anomaly-free.

Then online least squares with regularization parameter $\mu$ incurs regret

$$R_t(A) \leq \mu \frac{\|A\|^2_F}{\mu} + O\left(m^3n \max \left\{ \frac{C_\xi c^2t}{\mu}, \frac{C_\xi}{c^2_{1+\alpha}}, \frac{1}{c_1^{1+\alpha}c_2^{1+\alpha}} \left( \frac{\|A\|_2}{\mu} \right)^{\frac{1}{2+\alpha}} + \frac{C_\xi^{1+\alpha}t}{\mu^{\frac{1}{2+\alpha}}} \right\}^2 \cdot \ln \left( 1 + \frac{tB^2}{n} \right) \right).$$

If (1a) $\mu \geq \frac{4(\alpha+2)}{\alpha+1} \frac{\mu}{c^2_{1+\alpha}c_2^{1+\alpha}}$, (1b) $\|A\|_2 \leq \frac{C_\xi c^2 t}{\mu}$, (2) $\mu \leq \frac{4(\alpha+2)}{\alpha+1} \frac{t}{c_1^{1+\alpha}}$, and (3) $\mu \leq \frac{t}{C_\xi \|A\|}$, then

$$R_t(A) \leq \frac{m^3 \mu c^2 t}{\mu^{\frac{1}{2+\alpha}}} \cdot O\left( \frac{1}{\mu^{\frac{1}{2+\alpha}}} \right).$$

If $\|A\|_F = O(\sqrt{mn})$, $C_\xi = O(1)$, and $\mu = \frac{m^{\frac{\alpha+2}{\alpha+1}}}{c_1^{\frac{\alpha+2}{\alpha+1}}c_2^{\frac{\alpha+2}{\alpha+1}}}$.
satisfies these conditions, then

\[ R_t(A) = O \left( \frac{m^{2+\frac{1}{\alpha}}}{\alpha+1} nt^{\frac{\alpha+2}{\alpha+1}} \ln \left( 1 + \frac{tB^2}{n} \right) \right) \]  

Note that if \( t \to \infty \) while the other constants are fixed, the inequalities do hold for the choice of \( \mu \). The only inequality that is not immediately clear is (1a); it follows from comparing the exponents of \( t \):

\[ \frac{1}{2} + \frac{1}{\alpha} \geq \frac{\alpha+2}{\alpha+1} \quad \text{for} \quad \alpha \leq 1. \]

By Theorem 2.1 it suffices to bound \( \| A_t x_t - y_t \| \), which is done in Lemma B.5. We start with the following calculation.

**Lemma B.3.** Let \( x_t \in \mathbb{R}^m, A \in \mathbb{R}^{n \times m}, \xi_t \in \mathbb{R}^n \) for \( 0 \leq s \leq t - 1 \). Suppose \( y_s = Ax_s + \xi_s \) for each \( 0 \leq s \leq t - 1 \). Let \( A_t = \arg \min_{A \in \mathbb{R}^{n \times m}} \left[ \mu \| A \|_F^2 + \sum_{s=0}^{t-1} \| y_t - Ax_t \|_2^2 \right] \). Let

\[ \Sigma_t = \mu I_m + \sum_{s=0}^{t-1} x_s x_s^\top. \]

Then

\[ A_t x_t - y_t = \sum_{s=0}^{t-1} \xi_s x_s^\top \Sigma_t^{-1} x_t - \mu A \Sigma_t^{-1} x_t - \xi_t. \]  

**Proof.** We calculate

\[ A_t = \arg \min_A \left[ \mu \| A \|_F^2 + \sum_{s=0}^{t-1} \| y_t - Ax_t \|_2^2 \right] \]

\[ = \sum_{s=0}^{t-1} y_s x_s^\top \Sigma_t^{-1} = \sum_{s=0}^{t-1} (Ax_s x_s^\top \Sigma_t^{-1} + \xi_s x_s^\top \Sigma_t^{-1}) \]

\[ A = A \left( \sum_{s=0}^{t-1} x_s x_s^\top + \mu I_m \right) \Sigma_t^{-1} = \sum_{s=0}^{t-1} Ax_s x_s^\top \Sigma_t^{-1} + \mu A \Sigma_t^{-1} \]

\[ A_t - A = \sum_{s=0}^{t-1} \xi_s v_s^\top \Sigma_t^{-1} - \mu A \Sigma_t^{-1} \]

\[ A_t x_t - y_t = (A_t - A)x_t - \xi_t \]

\[ = \sum_{s=0}^{t-1} \xi_s x_s^\top \Sigma_t^{-1} x_t - \mu A \Sigma_t^{-1} x_t - \xi_t. \]

We now bound the size of the residual when condition 3 from Theorem B.2 holds. We focus on the one-dimensional case in Lemma B.4. Afterwards, we bound the residuals in the general case by diagonalization and reduction to the one-dimensional result in Lemma B.5.
Lemma B.4. Let $c, c_1, c_2$ be constants, $c_1 \leq \frac{1}{2}, c \geq \frac{1}{c_1}$. Let $0 < \alpha \leq 1$. Suppose that $(x_s)_{s\leq t}$ is $(c, c_1, c_2, \alpha)$-anomaly-free and suppose $|\xi_s| \leq C_\xi$ for each $s$, then for $a > 0$,

$$\sum_{s=0}^{t-1} \xi_s x_s \left(\mu + \sum_{s=0}^{t-1} x_s^2\right)^{-1} x_t + a \left|\mu \left(\mu + \sum_{s=0}^{t-1} x_s^2\right)^{-1} x_t\right| \leq O\left(\max \left\{\frac{C_\xi c^2 t}{\mu} + ac, \frac{C_\xi}{c_1^2} \frac{1}{c_1^\alpha + c_2^\alpha + \frac{1}{\mu^{\alpha + 2}} + \frac{C_\xi t^2}{\mu^{\alpha + 2}}}\right\}\right).$$

The regret scales as the square of this quantity, plus a term scaling as $\mu$. For the case $\alpha = 1$, to balance the terms, we set $\left(\frac{t^2}{\mu^2}\right) \sim \mu$, so $\mu = t^\frac{3}{2}$ with regret $\widetilde{O}(t^\frac{3}{2})$.

Proof. Let $M = \max_{0 \leq s \leq t-1} |x_s|$.

First suppose $M \leq c$. Then

$$\sum_{s=0}^{t} \xi_s x_s \left(\mu + \sum_{s=0}^{t-1} x_s^2\right)^{-1} x_t \leq C_\xi c^2 t$$
and the second term satisfies

$$\left|\mu \left(\mu + \sum_{s=0}^{t-1} x_s^2\right)^{-1} x_t\right| \leq c.$$

Now suppose $M > c$. Then there exists a subsequence $x_{i_1}, \ldots, x_{i_n}$ where $n = \lceil c_1 M^\alpha \rceil > 1$ and $i_j < t, |x_{i_j}| \geq c_2 M$ for each $j$. Let $S = \{i_1, \ldots, i_n\}$. We have

$$\sum_{k=1}^{n} |x_{i_k}| \leq \lceil c_1 M^\alpha \rceil M = O(c_1 M^{\alpha+1}) \quad \sum_{k=1}^{n} x_{i_k}^2 \geq \lceil c_1 M^\alpha \rceil (c_2 M)^2 = \Omega(c_1 c_2^2 M^{\alpha+2}).$$

Thus

$$\sum_{s=0}^{t-1} \xi_{s+1} x_s \left(\mu + \sum_{s=0}^{t-1} x_s^2\right)^{-1} x_t + a \left|\mu \left(\mu + \sum_{s=0}^{t-1} x_s^2\right)^{-1} x_t\right| \leq \frac{a \mu + c_1 M^{\alpha+1} + \sum_{i \in [t-1] \setminus S} |x_i|}{\mu + c_1 c_2^2 M^{\alpha+2} + \sum_{i \in [t-1] \setminus S} x_i^2}$$

$$\leq \max_{0 \leq x_i' \leq M} \frac{a \mu + c_1 M^{\alpha+1} + \sum_{i=1}^{t-1-n} x_i'}{\mu + c_1 c_2^2 M^{\alpha+2} + (t-1-n)x^2}$$

where the last inequality follows by Jensen’s inequality since $x \mapsto x^2$ is convex (holding $\sum_{i=1}^{t-1-n} x_i'$ constant, the smallest value of $\sum_{i=1}^{t-1-n} x_i'$ is attained when they are equal). Continuing,

$$\leq \max_{0 \leq x_i' \leq M} \left(\frac{C_\xi c_1 M^{\alpha+1}}{\mu + c_1 c_2^2 M^{\alpha+2}} + \frac{a \mu + C_\xi (t-1-n)x}{\mu + c_1 c_2^2 M^{\alpha+2} + (t-1-n)x^2}\right)$$

$$\leq \max_{0 \leq x_i' \leq M} \left(\frac{C_\xi c_1 M^{\alpha+1}}{\mu + c_1 c_2^2 M^{\alpha+2}} + \frac{a \mu + C_\xi tx}{\mu + c_1 c_2^2 M^{\alpha+2} + tx^2}\right)$$
because $x \mapsto \frac{az}{b+cx}$ is increasing for $a, b, c > 0$ and $x \geq 0$. Thus
\[
\sum_{s=0}^{t-1} \xi_s x_s \left( \mu + \sum_{s=0}^{t-1} x_s^2 \right)^{-1} x_t + a \left( \mu + \sum_{s=0}^{t-1} x_s^2 \right)^{-1} x_t
\]
\[
\lesssim M \cdot \max_{0 \leq x \leq M} \left( \frac{C \xi c_1 M^{\alpha+1}}{\mu + c_1 c_2 M^{\alpha+2}} + \frac{a \mu + C \xi t x}{\mu + c_1 c_2 M^{\alpha+2} + t x^2} \right)
\]
\[
\leq \max_{0 \leq x \leq M} \left( \frac{C \xi}{c_2^2} + \frac{a M \mu + C \xi M t x}{\mu + c_1 c_2 M^{\alpha+2} + t x^2} \right)
\]
The second term is bounded by
\[
a M \mu \left( \frac{1}{\mu} \right)^{\frac{\alpha+1}{\alpha+2}} \left( \frac{1}{c_1 c_2 M^{\alpha+2}} \right)^{\frac{1}{\alpha+2}} + C \xi M t x \left( \frac{1}{\mu} \right)^{\frac{\alpha}{\alpha+2}} \left( \frac{1}{c_1 c_2 M^{\alpha+2}} \right)^{\frac{1}{\alpha+2}} \left( \frac{1}{t x^2} \right)^{\frac{1}{2}}
\]
\[
\leq \frac{1}{c_1^{\alpha+2} c_2^{\alpha+2}} \left( a \mu^{\alpha+2} + \frac{C \xi t^\frac{1}{2} x^2}{\mu t^{\frac{1}{2}} \alpha+2} \right).
\]
\[\square\]

Now we are ready to bound (9) in the multidimensional case.

**Lemma B.5.** Suppose the conditions specified in Theorem B.2 are satisfied, then for each $0 \leq t \leq T - 1$,
\[
\|A_t x_t - y_t\| \leq O \left( m \max \left\{ \frac{c \xi c_2 t}{\mu} + \|A\|_2 c, \frac{c \xi}{c_2}, \alpha \frac{c_1^{\alpha+2} c_2^{\alpha+2}}{\alpha+2} \left( \|A\|_2 \frac{1}{\mu^{\alpha+2}} + \frac{C \xi t^\frac{1}{2}}{\mu t^{\frac{1}{2}} \alpha+2} \right) \right\} \right).
\]

**Proof.** We bound each of the terms in (9).

Because $\sum_{s=0}^{t-1} x_s x_s^\top$ is symmetric, we can find an orthogonal matrix $U$ such that $U \left( \sum_{s=0}^{t-1} x_s x_s^\top \right) U^\top$ is diagonal. Let $z_s = U x_s$. Then
\[
\sum_{s=0}^{t-1} \xi_s x_s^\top \left( \mu I_m + \sum_{s=0}^{t-1} x_s x_s^\top \right)^{-1} x_t = \sum_{s=0}^{t-1} \xi_s x_s^\top U^\top \left( \mu I_m + \sum_{s=0}^{t-1} U x_s x_s^\top U^\top \right)^{-1} U x_t
\]
\[
= \sum_{s=0}^{t-1} \xi_s z_s^\top \left( \mu I_m + \sum_{s=0}^{t-1} z_s z_s^\top \right)^{-1} z_t
\]
\[
= m \sum_{i=1}^{m} \sum_{s=0}^{t-1} \xi_s z_{si} \left( \mu + \sum_{s=0}^{t-1} z_{si}^2 \right)^{-1} z_{ti}
\]
(10)
where we can “decouple” the coordinates because \( \mu I + \sum_{s=0}^{t-1} z_s z_s^\top \) is diagonal. Similarly,

\[
\mu A \left( \mu I_m + \sum_{s=0}^{t-1} x_s x_s^\top \right)^{-1} x_t = \mu A U^\top \left( \mu I + \sum_{s=0}^{t-1} z_s z_s^\top \right)^{-1} z_t \\
= \sum_{i=1}^m (A U^\top)_i \mu \left( \mu I_m + \sum_{s=0}^{t-1} z_s^2 \right)^{-1} z_{ti}
\]

(11)

\[
\left\| \mu A \left( \mu I_m + \sum_{s=0}^{t-1} x_s x_s^\top \right)^{-1} x_t \right\| \leq \max_{1 \leq i \leq m} \left\| (A U^\top)_i \right\| \sum_{i=1}^m \mu \left( \mu I_m + \sum_{s=0}^{t-1} z_s^2 \right)^{-1} z_{ti} \\
\leq \|A\|_2 \sum_{i=1}^m \left\| (A U^\top)_i \right\| \mu \left( \mu I_m + \sum_{s=0}^{t-1} z_s^2 \right)^{-1} z_{ti}
\]

From the hypothesis of the lemma and the fact that \( z_{ti} = U_i x_t \), we conclude that \( z_{ti} \) satisfies the conditions of Lemma [B.3]. Apply Lemma [B.3] to the \( z_{ti} \) to obtain bounds for

\[
\sum_{s=0}^{t-1} \|\xi_s\| \left\| \mu I + \sum_{s=0}^{t-1} z_s^2 \right\|^{-1} z_{ti} + \|A\|_2 \mu \left( \mu I_m + \sum_{s=0}^{t-1} z_s^2 \right)^{-1} z_{ti}
\]

for each \( i \). Summing over over \( i \) gives a factor of \( m \), and gives a bound for \((10) + (11)\). Finally, the term \(-\xi_t \) contributes at most \( C_\xi \), which can be absorbed into the bound.

**Proof of Theorem [B.2]** The theorem follows from plugging in the bound on \( \|A_t x_t - y_t\| \) in Lemma [B.5] into the regret bound of Theorem [2.1].

For the second statement, we check that \((1a) \) implies \( C_1^2 c t \leq \frac{C_1^2 c t}{\mu} \leq \frac{1}{c_1^{1+\frac{1}{2}} c_2^{1+\frac{1}{2}}} \cdot \frac{C_1 t \frac{1}{2}}{\mu^{1+\frac{1}{2}}} \), \((1b) \) implies that \( \|A\|_2 c \leq \frac{C_1 c t}{\mu} \), \((2) \) implies that \( \frac{C_1}{c_2} \leq \frac{1}{c_1^{1+\frac{1}{2}} c_2^{1+\frac{1}{2}}} \cdot \frac{C_1 t \frac{1}{2}}{\mu^{1+\frac{1}{2}}} \), and \((3) \) implies that \( \|A\|_2 \mu^{1+\frac{1}{2}} \leq \frac{C_1 t \frac{1}{2}}{\mu^{1+\frac{1}{2}}} \). Then the maximum term is \( O \left( \frac{1}{c_1^{1+\frac{1}{2}} c_2^{1+\frac{1}{2}}} \cdot \frac{C_1 t \frac{1}{2}}{\mu^{1+\frac{1}{2}}} \right) \).

For the third statement, we note \( \mu \) was chosen to equate the two terms.

**C Proof of Theorem [4.2]** (fully observed system, adversarial noise)

We complete the details for the proof outline from Section [5]. We start with the following simple observation: if \( x_T \) is a linear combination of previous \( x_t \)’s with small coefficients, and \( x_T \) has large projection in some direction, then at least one of the \( x_t \)’s also has large projection in that direction.

**Lemma C.1.** Suppose there exist \( a_t \in \mathbb{R} \) and \( v \in \mathbb{R}^d \) such that

\[
x_T = \sum_{t=0}^{T-1} a_t x_t + v
\]

and \( \sum_{t=0}^{T-1} |a_t| \leq L_a, \|v\|_2 \leq L_v \).

Then for any unit vector \( w \in \mathbb{R}^d \), there exists \( 0 \leq t \leq T - 1 \) such that

\[
|w^\top x_t| \geq \frac{|w^\top x_T - L_v|}{L_a}.
\]
Proof. We have
\[ w^\top x_T = \sum_{t=0}^{T-1} a_t w^\top x_t + w^\top v. \] (14)

Applying Hölder’s inequality, there exists \( 0 \leq t \leq T - 1 \) such that
\[ |w^\top x_t| \geq \frac{|w^\top x_T - w^\top v|}{\sum_{t=0}^{T-1} |a_t|} \geq \frac{|w^\top x_T| - |w^\top v|}{La}. \] (15)

We then note that \( |w^\top v| \leq \|v\| \) as \( w \) is a unit vector, and the result follows.

C.1 State is a small \( \ell_1 \) combination of previous states (exp(\( d \)) version)

As a warm-up, we first give a simpler proof that obtains a bound on \( \sum_{t=1}^{T-1} |a_t| \) that is exponential in \( d \). This subsection is for exposition purposes only and may be skipped. In the next subsection we obtain a poly(\( d \)) bound.

Lemma C.2 (Large past \( x \)'s via Cayley-Hamilton). Suppose that \( A \) is diagonalizable as \( A = VDV^{-1} \) where \( \|V\| \|V^{-1}\| \leq C_1 \), and \( \rho(A) \leq 1 \). Then for any unit vector \( w \in \mathbb{R}^d \), there exist \( \min \left\{ \left\lfloor \frac{|w^\top x_i|}{\|w\|^2} \right\rfloor \right\} \) values of \( s \), \( 0 \leq s \leq t - 1 \), such that
\[ |w^\top x_s| \geq \frac{|w^\top x_t|}{2^{d+1}}. \]

Note that in fact the \( d \) in the bound can be replaced with the degree of the minimal polynomial.

Proof. By the Cayley-Hamilton Theorem, if \( p(x) = \sum_{i=0}^{d} a_i^{(1)} x^i \) is the characteristic polynomial of \( A \), then \( \sum_{i=0}^{d} a_i^{(1)} A^i = 0 \). We can bound the size of the coefficients as follows. Let \( r_1, \ldots, r_d \) be the roots of \( p(x) = 0 \). Then \( p(x) = \prod_{i=1}^{d} (x - r_i) \). Because \( \rho(A) \leq 1 \), every root satisfies \( |r_i| \leq 1 \). By the triangle inequality, the coefficients of \( p(x) \) are at most the corresponding coefficients of \( q(x) = \prod_{i=1}^{d} (x + |r_i|) \) in absolute value. The sum of coefficients of \( q(x) \) is \( q(1) \leq 2^d \), so \( \sum_{i=0}^{d} |a_i| \leq 2^d \).

We now proceed to bound the error term due to the noise. By unfolding the recurrence we obtain
\[ x_t = A^d x_{t-d} + \sum_{\tau=1}^{d} A^{d-\tau} \xi_{t-d+\tau} \]
\[ = \sum_{i=0}^{d-1} -a_i^{(1)} A^i x_{t-d} + \sum_{\tau=1}^{d} A^{d-\tau} \xi_{t-d+\tau} \]
\[ = \sum_{i=0}^{d-1} -a_i^{(1)} \left( x_{t-d+i} - \sum_{\tau=1}^{i} A^{i-\tau} \xi_{t-d+\tau} \right) + \sum_{\tau=1}^{d} A^{d-\tau} \xi_{t-d+\tau} \]
\[ = \sum_{i=0}^{d-1} -a_i^{(1)} x_{t-d+i} + \sum_{i=0}^{d-1} \left( \sum_{\tau=1}^{i} a_i^{(1)} A^{i-\tau} \xi_{t-d+\tau} \right) + \sum_{\tau=1}^{d} A^{d-\tau} \xi_{t-d+\tau} \]
\[ =: v^{(1)} \]
Note that $\|A^i\xi\| \leq \|V D^i V^{-1} \| \|\xi\| \leq C_A \|\xi\|$, and $\|\xi\| \leq 1$ for each $i$. We write $x_t = -\sum_{i=1}^{d-1} a_i^{(1)} x_{t-d+i} + v^{(1)}$ where

$$\|v^{(1)}\| = \left\| \sum_{i=0}^{d-1} a_i^{(1)} \sum_{\tau=1}^{i} A^{i-\tau} \xi_{t-d+i} + \sum_{\tau=1}^{d} A^{d-\tau} \xi_{t-d+i} \right\|$$

\[
\leq \sum_{i=0}^{d-1} |a_i^{(1)}| \sum_{\tau=1}^{i} C_A \|\xi_{t-d+i}\| + \sum_{\tau=1}^{d} C_A \|\xi_{t-d+i}\|
\]

\[
\leq 2^d (d-1) C_A + dC_A \leq d2^d C_A
\]

If $w \in \mathbb{R}^d$ is a unit vector such that $\|w^\top x_t\| \geq d2^{d+1} C_A$, we have $|w^\top x_t| \geq 2 \|v^{(1)}\|$. Noting that $w^\top x_t = \sum_{i=0}^{d-1} a_i^{(1)} x_{t-d+i} + v^{(1)}$, by Lemma C.3 there exists an index $0 \leq i \leq d - 1$ such that

$$|w^\top x_{t-d+i}| \geq \frac{|w^\top x_t| - \|v^{(1)}\|}{\sum_{i=0}^{d-1} |a_i|} \geq \frac{|w^\top x_t|}{2 \sum_{i=0}^{d-1} |a_i|} \geq \frac{|w^\top x_t|}{2^d + 1}$$

In order to obtain many large past $x$’s, we apply the same argument on sequences $x_t, x_{t-k}, \ldots, x_{t-kd}$ by considering the recurrence

$$x_t = A' x_{t-k} + \xi_t^{(k)}$$

$$A' = A^k$$

$$\xi_t^{(k)} = \sum_{j=1}^{k} A^{k-j} \xi_{t-k+j}.$$  

Let $p_k(x) = \sum_{i=0}^{d} a_i^{(k)} x^i$ be the characteristic polynomial of $A^k$. We have

$$\|v^{(k)}\| = \left\| \sum_{i=0}^{d-1} a_i^{(k)} \sum_{\tau=1}^{i} A^{i-\tau} \xi_{t-dk+i}^{(k)} + \sum_{\tau=1}^{d} A^{d-\tau} \xi_{t-dk+i}^{(k)} \right\|$$

\[
\leq k2^d (d-1) C_A + kd C_A \leq kd2^d C_A
\]

so that we obtain $x_t = -\sum_{i=0}^{d-1} a_i^{(k)} x_{t-k(d-i)} + v^{(k)}$ with $\sum_{i=0}^{d} |a_i^{(k)}| \leq 2^d$ and $\|v^{(k)}\| \leq kd2^d C_A$.

We then pick $k = 1, 2, \ldots, \min \left\{ \frac{|w^\top x_t|}{2^d C_A}, \left\lfloor \frac{\delta}{\mu} \right\rfloor \right\}$. For each choice of $k$, we know by design that $|w^\top x_t| \geq 2 \|v^{(k)}\|_2$, and therefore there must exist an $x$ in the sequence $x_{t-k}, \ldots, x_{t-kd}$ such that $|w^\top x| \geq \frac{|w^\top x_t|}{2^d + 1}$. In this way, we are able to collect in total $L = \min \left\{ \frac{|w^\top x_t|}{2^d C_A}, \left\lfloor \frac{\delta}{\mu} \right\rfloor \right\}$ many such $x$’s. To finish the argument, we note that out of the $L$ collected $x$’s, there are at least $\left\lfloor \frac{\delta}{\mu} \right\rfloor$ distinct ones, since one $x$ can appear in at most $d$ different sequences. \hfill \qed

Plugging in the conclusion of Lemma C.2 into Theorem B.2 we can obtain the following theorem.

**Theorem C.3.** Assume Assumptions [\text{J.}] and furthermore suppose $A$ is diagonalizable and $u_t = 0$ for each $t$. Then online least squares (Algorithm 4) with $\mu = T^\frac{\delta}{4}$ achieves regret

$$R_T(\mathcal{A}, \mathcal{B}) \leq T^\frac{\delta}{4} \exp(O(d)) \text{poly}(C, R, \ln T).$$

We omit the details, as we will prove the stronger Theorem 1.2
C.2 State is a small $\ell_1$ combination of previous states ($\text{poly}(d)$ version)

We will use the following notation to keep track of the growth of $A^k$.

**Definition C.4.** Given a matrix $A \in \mathbb{R}^{d \times d}$, define $f_A(k) := \|A^k\|_1$.

Given a set $K \subseteq \mathbb{R}^d$, define $f_{A,K}(k) := \max_{\xi \in K} \|A^k\xi\|_1$.

The first step of the proof is to show the following. Denote the $L^2$ ball of radius $r$ in $d$ dimensions by $B_r^d = \{ \|x\|_2 \leq r : x \in \mathbb{R}^d \}$.

**Lemma C.5.** Suppose that $x_0 \in K_0 \subset \mathbb{R}^d$ and $x_t = Ax_{t-1} + \xi_t$ with $A \in \mathbb{R}^{d \times d}$ and $\xi_t \in K$ for $1 \leq t \leq T$. Suppose $M \geq 1$ and $\|x_t\| \leq M$ for $0 \leq t \leq T$. Then there exist $a_t \in \mathbb{R}$ and $v \in \mathbb{R}^d$ such that

$$x_T = \sum_{t=0}^{T-1} a_t x_t + v$$  \hspace{1cm} (21)

and letting $k' = \lfloor d \log_2(M) \rfloor$,

$$\sum_{t=0}^{T-1} |a_t| \leq \frac{2}{\ln 2} d^2$$  \hspace{1cm} (22)

$$\|v\|_2 \leq \max_{0 \leq k \leq k'} f_{A,K_0 \cup B_r^d}(k) + \left( k' - 1 \right) \left( \frac{2}{\ln 2} d + 1 \right) \cdot (23)

We emphasize that we will only need the existence of $a_t$, $x_t$, and $v$; the algorithm will not need to compute the linear decomposition. We mention that the related notion of volumetric spanners based on the $L^2$ norm that has been applied to online convex optimization [HK16].

Note that we can bound $f(k)$ in terms of the size of the Jordan blocks (Lemma C.9). To prove Lemma C.5 we will use two lemmas (Lemma C.7 and Lemma C.8).

**C.2.1 Bounding $I_t$**

Define the convex set spanned by a set $S \subset \mathbb{R}^d$ by

$$\Delta(S) := \left\{ \sum_{u \in S} a_u u : a_u \in \mathbb{R}, \sum_{u \in S} |a_u| \leq 1, a_u = 0 \text{ for all but finitely many } u \right\}.$$  \hspace{1cm} (24)

Suppose that $S$ is compact and spans $\mathbb{R}^d$. The centrally symmetric convex set $\Delta(S)$ defines the norm (called the Minkowski functional of $\Delta(S)$)

$$\|x\|_{\Delta(S)} = \inf_{a_u \neq 0 \text{ f.a.b.f.m. } u} \sum_{u \in S} |a_u|,$$  \hspace{1cm} (25)

where f.a.b.f.m. abbreviates “for all but finitely many.” First we note that we can in fact replace the inf with the min over linear combinations of $d + 1$ terms.
Proposition C.6. Suppose \( S \subset \mathbb{R}^d \) is compact and spans \( \mathbb{R}^d \). The following hold:

\[
\Delta(S) = \left\{ \sum_{i=1}^{d+1} a_i u_i : a_i \in \mathbb{R}, u_i \in S, \sum_{i=1}^{d+1} |a_i| \leq 1 \right\}
\]

\[
\|x\|_{\Delta(S)} = \min_{x = \sum_{i=1}^{d+1} a_i u_i, u_i \in S} \sum_{i=1}^{d+1} |a_i|.
\]

Proof. If \( v \in \Delta(S) \) has a representation \( v = \sum_{u \in S} a_u u \) in the form of (24), then by Carathéodory’s Theorem on \( \sum_{u \in S} |a_u| \), it can be written also as \( v = \sum_{i=1}^{d+1} b_i u_i \) for \( \sum_{i=1}^{d+1} |b_i| \leq \sum_{u \in S} |a_u|, u_i \in S \).

Next, note that \( \Delta(S) \) is closed: if \( v_i \in \Delta(S) \), and we can write \( v_i = \sum_{j=1}^{d+1} a_{i,j} u_{i,j} \). By compactness of \([−1, 1]^{d+1} \times S^{d+1}\), there is a subsequence of \((a_{i,j})_{j=1}^{d+1}, u_{i,j})_{j=1}^{d+1}\) that converges, say to \((a_j)_{j=1}^{d+1}, u_j)_{j=1}^{d+1}\). Then \( v = \sum_{j=1}^{d+1} a_j u_j \). Finally, this implies \( \|x\|_{\Delta(S)} = \inf_{x = \sum_{u \in S} a_u u} \sum_{u \in S} |a_u| = \min_{x = \sum_{i=1}^{d+1} a_i u_i, u_i \in S} \sum_{i=1}^{d+1} |a_i| \).

Define

\[
\Delta'(S) = \Delta(S \cup \{v : \|v\|_2 \leq 1\}) = \left\{ \left( \sum_{u \in S} a_u u \right) + v : a_u \in \mathbb{R}, v \in \mathbb{R}^d, \sum_{u \in S} |a_u| + \|v\|_2 \leq 1 \right\} \tag{26}
\]

(note that the \( L^2 \) norm is used with \( v \)). Then

\[
\|x\|_{\Delta'(S)} = \min_{y = \left( \sum_{u \in S} a_u u \right) + v} \left( \sum_{u \in S} |a_u| + \|v\|_2 \right). \tag{27}
\]

Now define

\[
\Delta_t = \Delta'\left(\{x_s : 0 \leq s \leq t\}\right) \tag{28}
\]

for \(-1 \leq t \leq T\). We need to keep track of the number of times when \( x_t \) is not a small linear combination of previous \( x_s \)'s, so let

\[
I_t = \left\{ 0 \leq s \leq t : \|x_s\|_{\Delta_{s-1}} \geq \frac{2}{\ln 2} \right\}. \tag{29}
\]

We first show that if \( s \in I_t \), then there is a large increase in volume between \( \Delta_{s-1} \) and \( \Delta_s \). Then, we use a bound on the volume of \( \Delta_T \) to bound \( |I_T| \).

Lemma C.7. Let \( w \) be such that \( \|w\|_{\Delta(S)} \geq 2Cd \). Then

\[
\text{Vol}(\Delta(S \cup \{w\})) \geq (1 + 2e^{-1/C}) \text{Vol}(\Delta(S)). \tag{30}
\]

Proof. Consider the set \( \Delta(S) \) slightly shrunk, and translated along the direction of \( w \):

\[
\pm \frac{1}{Cd} w + \left(1 - \frac{1}{Cd}\right) \Delta(S) \subseteq \Delta(S \cup \{w\}). \tag{31}
\]
Now for \( u \in \Delta(S) \), \( \|\pm \frac{1}{Cd} w + (1 - \frac{1}{Cd}) u\|_{\Delta(S)} \geq \frac{1}{Cd} \|w\|_{\Delta(S)} - \|u\|_{\Delta(S)} > \frac{1}{Cd}(2Cd) - 1 \geq 1 \). Hence, 
\( \pm \frac{1}{Cd} w + (1 - \frac{1}{Cd}) \Delta(S) \) does not intersect \( \Delta(S) \). This means that

\[
\text{Vol}(\Delta(S \cup \{w\})) \geq \text{Vol}(\Delta(S)) + \text{Vol} \left( \pm \frac{1}{Cd} w + \left(1 - \frac{1}{Cd}\right) \Delta(S) \right) 
\geq \text{Vol}(\Delta(S)) + 2 \left(1 - \frac{1}{Cd}\right)^d \text{Vol}(\Delta(S))
\geq (1 + 2e^{-1/C}) \text{Vol}(\Delta(S)).
\]

\( \square \)

**Lemma C.8.** Let \( M = \max_{0 \leq t \leq T} \|x_t\| \). Then \( |I_T| \leq d \log_2 M \).

**Proof.** If \(|I_t| > |I_{t-1}|\), then by definition \( \|x_t\|_{\Delta_{t-1}} \geq \frac{2}{1-e^2} d \). By Lemma C.7 \( \text{Vol}(\Delta_t) \geq 2 \text{Vol}(\Delta_{t-1}) \). Hence

\[
2^{|I_T|} \text{Vol}(B_t^d) = 2^{|I_T|} \text{Vol}(\Delta_{-1}) \leq \text{Vol}(\Delta_T) \leq M^d \text{Vol}(B_t^d).
\]

Taking logarithms gives \( |I_T| \leq d \log_2 M \). \( \square \)

**C.2.2 Bounding \( \|x_t\|_{\Delta_{t-1}} \)**

**Proof of Lemma C.5** First we show that if \( x_t \) is a linear combination of previous \( x_s \)'s with small coefficients, then so is \( x_{t+k} \) for small \( k \). Suppose that

\[
x_t = \sum_{s=0}^{t-1} a_s x_s + v.
\]

We claim by induction that for any \( k \geq 0 \),

\[
x_{t+k} = \sum_{s=0}^{t-1} a_s x_{s+k} + A^k v + \sum_{j=1}^{k} A^{k-j} \left( \sum_{s=0}^{t-1} a_s \xi_{s+j} + \xi_{t+j} \right).
\]

Indeed, if this holds for \( k \), then

\[
x_{t+k+1} = Ax_{t+k} + \xi_{t+k+1}
= A \left( \sum_{s=0}^{t-1} a_s x_{s+k} + A^k v + \sum_{j=1}^{k} A^{k-j} \left( \sum_{s=0}^{t-1} a_s \xi_{s+j} + \xi_{t+j} \right) \right) + \xi_{t+k+1}
= \left( \sum_{s=0}^{t-1} a_s Ax_{s+k} + A^{k+1} v + \sum_{j=1}^{k} A^{k+1-j} \left( \sum_{s=0}^{t-1} a_s \xi_{s+j} + \xi_{t+j} \right) \right) + \xi_{t+k+1}
= \left( \sum_{s=0}^{t-1} a_s (x_{s+k+1} - \xi_{s+k+1}) + A^{k+1} v + \sum_{j=1}^{k} A^{k+1-j} \left( \sum_{s=0}^{t-1} a_s \xi_{s+j} + \xi_{t+j} \right) \right) + \xi_{t+k+1}
= \sum_{s=0}^{t-1} a_s x_{s+k+1} + A^{k+1} v + \sum_{j=1}^{k+1} A^{k+1-j} \left( \sum_{s=0}^{t-1} a_s \xi_{s+j+1} + \xi_{t+j+1} \right).
\]
Now we consider the sizes of the coefficients in (37). If $\sum_{s=0}^{t-1} |a_s| = L_a$ and $\|v\|_2 = L_v$, then (37) expresses $x_{t+k+1}$ as a linear combination with

$$\sum_{s=0}^{t-1} |a_s| = L_a$$

(43)

$$\left\| A^k v + \sum_{j=1}^{k} A^{k-j} \left( \sum_{s=0}^{t-1} -a_s \xi_{s+j} + \xi_{t+j} \right) \right\| \leq \left\| A^k v \right\| + \left( \sum_{s=0}^{t-1} f_{A,K}(s) \right) \left( \sum_{s=0}^{t-1} |a_s| + 1 \right)$$

(44)

$$\leq \left\| A^k v \right\| + \left( \sum_{s=0}^{k-1} f_{A,K}(s) \right) (L_a + 1).$$

(45)

By Lemma C.8, $|I_T| \leq d \log_2 M$, so for $1 \leq t \leq T$, there exists $k \leq |I_T| \leq k' = \lfloor d \log_2 (M) \rfloor$ such that either

- $t - k \not\in I_T$, so $\|x_{t-k}\|_{\Delta_{t-k-1}} \leq \frac{2}{\ln^2 d}$, or
- $t - k = 0$, so $x_{t-k} = x_0 \in K_0$.

In either case, we can write $x_{t-k} = \sum_{s=0}^{t-1} a_s x_s + v$ with $\sum_{s=0}^{t-1} |a_s| \leq L_a := \frac{2}{\ln^2 d}$ and $v \in K_0 \cup B_{\frac{2}{\ln^2 d}}$. Then by (43) and (45), we can write $x_t$ as

$$x_t = \sum_{s=0}^{t-1} a'_s x_s + v'$$

(46)

with

$$\sum_{s=0}^{t-1} |a'_s| \leq \frac{2}{\ln^2 d}$$

(47)

$$\|v\|_2 \leq \|A^k v\| + \left( \sum_{s=0}^{k-1} f_{A,K}(s) \right) (L_a + 1)$$

(48)

$$\leq \max_{0 \leq k \leq k'} \sum_{s=0}^{k} f_{A,K}(s) \left( \frac{2}{\ln^2 d} + 1 \right).$$

(49)

\[ \square \]

\textbf{C.2.3 Bound in terms of Jordan form}

\textbf{Lemma C.9.} Suppose that $A$ has spectral radius $\leq 1$ and $A = SJS^{-1}$ with $\|S\|_2 \|S^{-1}\|_2 \leq C_A$ and $J$ has Jordan blocks of rank $\leq r$. Then

$$\left\| A^k \right\|_2 \leq \left( \frac{k + r}{r - 1} \right) C_A \leq (k + 1)^{r-1} C_A$$

(50)

$$\sum_{s=0}^{k} \|A^s\|_2 \leq \left( \frac{k + r + 1}{r} \right) C_A \leq (k + 1)^r C_A$$

(51)
Proof. Let \( J_{\lambda,r} = \begin{pmatrix} \lambda^{1} & \cdots & \lambda \end{pmatrix} \in \mathbb{R}^{r \times r} \). Then entrywise, \( J_{\lambda,r}^k \) has absolute value at most \( J_{1,r}^k = \left( \begin{array}{c} 1 \quad (k-1) \\ \vdots \\ 1 \end{array} \right) . \) We have for \( k \geq 1 \) that

\[
\| J_{\lambda,r}^k \|_2 \leq \| J_{1,r}^k \|_2 \leq \| J_{1,r}^1 \|_2 \leq C_A \| J_{\lambda,r}^k \|_2 .
\]

By decomposing into Jordan blocks, we find that

\[
A^k \|_2 \leq S^k \|_2 \leq S^{-1} \|_2 \leq C_A \| J_{\lambda,r}^k \|_2 .
\]

Together (54) and (55) give (50). Summing over \( k \) gives (51). \( \square \)

C.3 Concluding the states are anomaly-free

We need the following number-theoretic lemma.

Lemma C.10 ([Nat13, Theorem 6.3]). There exists a constant \( C > 0 \) such that for all \( x \geq 2 \),

\[
\prod_{1 < p \leq x, p \text{ prime}} p \geq x^{C_x}.
\]

Lemma C.11. Let \( T > 0 \). Suppose that \( \| x_0 \| \leq C_0 \) and \( x_t = A x_{t-1} + \xi_t \) with \( \xi_t \in K \) for \( 1 \leq t \leq T \). Let \( k' = \lfloor d \log_2(M) \rfloor \) and let

\[
L_v(p) = \max_{0 \leq k \leq (p' + 1) - 1} f_A(k) \max \left\{ \frac{2}{\ln 2} d, C_0 \right\} + \left( \sum_{k=0}^{p(k'+1)-2} f_{A,K}(k) \right) \left( \frac{2}{\ln 2} d + 2 \right)
\]

Let \( w \in \mathbb{R}^d \) be a unit vector. Suppose \( M \geq 1 \), \( \| x_t \| \leq M \) for \( 1 \leq t \leq T \). Suppose \( c \geq \frac{1}{\ln 2} d C_0 \) and \( Q(x) \) is a function such that whenever \( x > c \), then \( 2 \leq Q(x) \) and for all \( p \leq Q(x) \), we have \( x \geq 2L_v(p) \).

Then whenever \( |w^\top x_T| > c \), there are at least \( \Omega \left( \frac{Q(\|w^\top x_T\|)}{\ln T} \right) \) values of \( s \), \( 0 \leq s < t \), such that \( |w^\top x_s| \geq \frac{\ln 2}{4d} |w^\top x_T| . \)

26
Proof. For $p \leq T$, we apply Lemma C.1 with the bounds from Lemma C.5 with the sequence $x_{T \mod p}, \ldots, x_{T-p}, x_T$. This satisfies the conditions of Lemma C.5 with

\begin{equation}
x_t = A' x_{t-p} + \xi_t^{(p)}
\end{equation}
\begin{equation}
A' = A^p
\end{equation}
\begin{equation}
x_{T \mod p} \in K'_0 := A^{T \mod p} K_0 + A^{(T \mod p)-1} K + \ldots + K
\end{equation}
\begin{equation}
\xi_t^{(p)} = \sum_{j=1}^{p} A^{p-j} \xi_{t-p+j} \in K' := \sum_{j=1}^{p} A^{p-j} K.
\end{equation}

We calculate

\begin{equation}
\max_{0 \leq k \leq k'} f_{A',K_{0}' \cup B^d} \left( \frac{k}{m^2} \right)
= \max \left\{ \max_{0 \leq k \leq k'} \left( A^{(T \mod p)+kp,v} + \sum_{j=1}^{T \mod p} A^{(T \mod p)-j+kp} \xi_j \right), \max_{0 \leq k \leq k'} \left\| A^k \right\| \frac{2}{\ln 2} \frac{1}{d} \right\}
\end{equation}
\begin{equation}
\leq \max_{0 \leq k \leq (p+1) \cdot 2} f_A(k) \max \left\{ \frac{2}{\ln 2} d, C_0 \right\} + \sum_{k=0}^{p(k' + 1) - 2} f_{A,K}(k).
\end{equation}

and

\begin{equation}
\sum_{k=0}^{k'-1} f_{A',K'}(k) = \sum_{k=0}^{k'-1} \max_{\xi_0, \ldots, \xi_{p-1} \in K} \left\| \sum_{j=1}^{p} A^{pk+p-j} \xi_j \right\| \leq \sum_{k=0}^{k'-1} \max_{\xi \in K} \left\| A^k \xi \right\| = \sum_{k=0}^{p(k' - 1)} f_{A,K}(k).
\end{equation}

Then for the sequence $x_{T \mod p}, \ldots, x_T$, the $L_v$ in Lemma C.5 equals

\begin{equation}
\max_{0 \leq k \leq k'} f_{A',K_{0}' \cup B^d} \left( \frac{k}{m^2} \right) + \left( \sum_{k=0}^{k'-1} f_{A',K'}(k) \right) \left( \frac{2}{\ln 2} d + 1 \right)
\end{equation}
\begin{equation}
\leq \max_{0 \leq k \leq p(k' + 1) - 1} f_A(k) \max \left\{ \frac{2}{\ln 2} d, C_0 \right\} + \left( \sum_{k=0}^{p(k' + 1) - 2} f_{A,K}(k) \right) \left( \frac{2}{\ln 2} d + 2 \right) =: L_v(p)
\end{equation}

using (64) and (65). Apply Lemma C.1 to get that there exists $k \in \mathbb{N}$ such that

\begin{equation}
|w^\top x_{T-kp}| \geq \frac{|w^\top x_T| - L_v(p)}{2 \ln 2 d}.
\end{equation}

When $|w^\top x_T| > c$, and $p \leq Q(|w^\top x_T|)$, by assumption $|w^\top x_T| \geq 2L_v(p)$ and hence $\frac{|w^\top x_T| - L_v(p)}{2 \ln 2 d} \geq \frac{|w^\top x_T|}{2 \ln 2 d}$. Then equation (68) becomes: there exists $k \in \mathbb{N}$ such that

\begin{equation}
|w^\top x_{T-kp}| \geq \frac{\ln 2}{4d} |w^\top x_T|
\end{equation}

27
Put another way, there exists $s$ such that $|w^T x_s| \geq \frac{\ln 2}{\ln d} |w^T x_T|$ and $p$ divides $T-s$. Let $Q = Q(||w^T x_T||)$. This means that $\prod_{s=0}^{T-n} |w^T x_s| (T-s)$ to be divisible by all primes $p \leq \min\{Q, T\} = Q$. (Note $Q \leq T$ because otherwise, $[69]$ would hold for $p = T < Q$ and we have $C_0 \geq |w^T x_0| > \frac{\ln 2}{\ln d} |w^T x_T| \geq \frac{\ln 2}{\ln d} c$, contradiction.) Let $N = \left\{ s : |w^T x_s| \geq \frac{|w^T x_T|}{2\ln(p)} \right\}$. By Lemma C.10 for some $C' > 0$,

$$T^N \geq \prod_{s=0}^{T-n} (T-s) \geq \prod_{\text{prime } p \leq X} p \geq Q^{C'Q}. \tag{70}$$

Thus

$$N \geq \frac{C'Q \ln Q}{\ln T} \geq \Omega \left( \frac{Q}{\ln T} \right). \tag{71}$$

\[ \square \]

### C.4 Finishing the proof

**Lemma C.12.** Assume Assumption 4.1. Then

$$\max_{0 \leq k \leq T} \|x_k\| \leq (T + 1)^{t-1} C_A C_0 + T^r C_A (C_B C_A + C_\xi). \tag{72}$$

**Proof.** Using Lemma C.9 we have

$$x_t = A^t v + \sum_{k=0}^{t-1} A^k B u_{t-1-k} + \sum_{k=0}^{t-1} A^k \xi_{t-k} \quad \text{max}_{0 \leq k \leq T} \|x_k\| \leq \max_{0 \leq k \leq T} \|A^k\| C_0 + \sum_{k=0}^{T-1} \|A^k B\| C_u + \sum_{k=0}^{T-1} \|A^k\| C_\xi \leq (T + 1)^{t-1} C_A C_0 + C_A C_B C_u T^r + C_A C_\xi T^r. \quad \square$$

**Proof of Theorem 4.2.** Let $A' = \left( \begin{smallmatrix} A & B \\ O & O \end{smallmatrix} \right)$. We apply Lemma C.11 to the system

$$\begin{pmatrix} x_t \\ u_t \end{pmatrix} = A' \begin{pmatrix} x_{t-1} \\ u_{t-1} \end{pmatrix} + \begin{pmatrix} \xi_{t} \\ u_{t} \end{pmatrix} \tag{73}$$

with $\left( \begin{smallmatrix} \xi_t \\ u_t \end{smallmatrix} \right) \in K := B_{C_\xi}^d \oplus B_{C_u}^d$ for $1 \leq t \leq T$. Let $k' = \lfloor (d + m) \log_2(M) \rfloor$ and $C = C_A (C_\xi + C_B C_u)$. Note that

$$f_{A',K}(k) = \max_{\left( \begin{smallmatrix} \xi_t \\ u_t \end{smallmatrix} \right) \in K} \left( \|A^k \xi\|_2 + \begin{cases} \|A^{k-1} B u\|_2, & k \geq 1 \\ C_u, & k = 0 \end{cases} \right) \tag{74}$$

$$\sum_{k=0}^{p(k'+1)-2} f_{A',K}(k) \leq \sum_{k=0}^{p(k'-1)-2} (f_A(k) C_\xi + f_A(k) C_B C_u) + C_u \tag{74}$$

28
Then using Lemma [C.9], \( L_v(p) \) in Lemma [C.11] equals

\[
L_v(p) = \max_{0 \leq k \leq p(k' + 1) - 1} f_A'(k) \max \left\{ \frac{2}{\ln 2} (d + m), C_0 \right\} + \left( \sum_{k=0}^{p(k' + 1) - 2} f_{A',K}(k) \right) \left( \frac{2}{\ln 2} (d + m) + 2 \right)
\]

\[
\leq \max_{0 \leq k \leq p(k' + 1) - 1} f_A'(k) \max \left\{ \frac{2}{\ln 2} (d + m), C_0 \right\}
\]

\[
+ \left( \sum_{k=0}^{p(k' + 1) - 2} (f_A(k)C_x + f_A(k)C_BC_u) + C_u \right) \left( \frac{2}{\ln 2} (d + m) + 2 \right)
\]

\[
\leq (p(k' + 1))^{r-1} \max \left\{ \frac{2}{\ln 2} (d + m), C_0 \right\} + [C(p(k' + 1))]^{r} + C_u \left( \frac{2}{\ln 2} (d + m) + 2 \right)
\]

\[
\leq p^r(k' + 1)^r \left( \frac{2}{\ln 2} (d + m)(C + 1) + C_0 + 2 \right) + C_u \left( \frac{2}{\ln 2} (d + m) + 2 \right) . \tag{75}
\]

Let

\[
Q(x) = \left( \frac{x - 2C_u \left( \frac{2}{\ln 2} (d + m) + 2 \right)}{2C(k' + 1)^r \left( \frac{2}{\ln 2} (d + m)(C + 1) + C_0 + 2 \right)} \right) ^{\frac{1}{r}}
\]

\[
c = \max \left\{ 2^{r+1}C(k' + 1)^r \left( \frac{2}{\ln 2} (d + m)(C + 1) + C_0 + 2 \right) + 4C_u \left( \frac{2}{\ln 2} (d + m) + 2 \right), \frac{4dC_0}{\ln 2} \right\} .
\]

It is easy to check that when \( x \geq c \), then \( 2 \leq Q(x) \) and for all \( p \leq Q(x) \), \( x \geq 2L_v(p) \). Moreover, for \( x \geq c \), we have \( x \geq 4C_u \left( \frac{2}{\ln 2} (d + m) + 2 \right) \), so \( Q(x) \geq \left( \frac{x}{4C(k' + 1)^r \left( \frac{2}{\ln 2} (d + m)(C + 1) + C_0 + 2 \right)} \right) ^{\frac{1}{r}} \). By Lemma [C.11] the states are \((c, c_1, c_2, \alpha)\)-anomaly-free, with

\[
\alpha = \frac{1}{r}
\]

\[
c = \max \left\{ 2^{r+1}C(k' + 1)^r \left( \frac{2}{\ln 2} (d + m)(C + 1) + C_0 + 2 \right) + 4C_u \left( \frac{2}{\ln 2} (d + m) + 2 \right), \frac{4dC_0}{\ln 2} \right\}
\]

\[
c_1 = \Theta \left( \frac{1}{C^\frac{1}{r}(k' + 1)^r \left( \frac{2}{\ln 2} (d + m)(C + 1) + C_0 \right)^{\frac{1}{r}} \ln T} \right)
\]

\[
c_2 = \frac{\ln 2}{4d},
\]

satisfying the hypothesis of Theorem [B.2]. By Theorem [B.2] the regret is

\[
R_T \leq \mu R^2 + O \left( d^2 \max \left\{ \frac{C\xi^2 C^2 T}{\mu} + \|A\|_2 \frac{C\xi}{c_2} \frac{1}{c_1 c_2^{\frac{1}{r}}} \left( \frac{\|A\|_2 \mu^{\frac{1}{r}} + C\xi T^\frac{1}{r}}{\mu^{\frac{1}{r}} - \frac{1}{\alpha+2}} \right) \right\} \right)^2
\]

\[
\cdot d(d + m) \ln \left( 1 + \frac{TM^2}{d} \right).
\]

Plugging in \( \mu = T^{\frac{2r+1}{2r+2}} \), and using the bound \( M \leq (T + 1)^{r-1} C_A C_0 + T^r C_A (C_B C_u + C_\xi) \) from Lemma [C.12], we obtain the theorem. Note that the only terms with an \( r \)th power are the two
terms involving $c$. The dependence on $T$ of the larger such term is $\frac{T}{\mu} = T^{\frac{1}{2r+2}}$, hence the additive term in (48).

We now simplify the bound when all the constants are $O(1)$ and $\|A\|_F = O(\sqrt{md})$. We have $c_1 = \Omega\left(\frac{1}{(d+\alpha)\ln T(d+\alpha)\ln T}\right)$ and $c_2 = \Omega\left(\frac{1}{\alpha}\right)$. Using (86) in Theorem [3.2] with $\mu = \frac{m^{\frac{2r+1}{2}} T^{\frac{2r+1}{2r+2}}}{c_1 + c_2}$, we obtain the bound (as $T \to \infty$)

$$R_T = O \left( \frac{mdm^{\frac{2r+1}{2r+2}} T^{\frac{2r+1}{2r+2}} \ln T}{c_1 + c_2} \right)$$

$$= O \left( m^{2r+1} T^{\frac{2r+1}{2r+2}} r \ln T \cdot (d + m) ^{\frac{2r+1}{2r+2}} (\ln T)^2 \right)$$

$$= O \left( m^{2r+1} r^d \ln T \right)$$

Note that Corollary [4.3] follows from plugging $r = 1$ into (76).

\[\square\]

### D Proof of Theorem 4.4 (fully observed system, stochastic noise)

**Lemma D.1.** Let $v_t, w_t \in \mathbb{R}^d$ for $0 \leq t \leq T - 1$. Suppose that the following hold.

- For any $0 \leq t \leq T - 1$, there exist $a_s \in \mathbb{R}$ such that

  $$v_t = \sum_{s=0}^{t-1} a_s v_s + v, \quad \sqrt{\sum_{s=0}^{t-1} a_s^2} \leq L_a, \quad \|v\|_2 \leq L_v. \quad (77)$$

- $w_t = Av_t + \epsilon_{t+1} + \xi_{t+1}$ where $\|A\|_2 \leq R$, $\|\epsilon_t\| \leq C_\epsilon$, and $\xi_t$, $1 \leq t \leq T$ are random variables such that $\xi_{t+1}|\xi_1, \ldots, \xi_t$ is mean 0 and $C_\xi$-subgaussian for $0 \leq t \leq T - 1$.

- $\|v_t\| \leq g(t)$ for $0 \leq t \leq T - 1$.

Let $L' > 0$, and let

$$\varepsilon_{\text{net}} = \frac{1}{\sum_{s=0}^{T-1} g(s)} \quad (78)$$

$$R_z = \mu^{-\frac{1}{2}} \left( \frac{L_a^2 + L_v^2}{\mu} \right)^{\frac{1}{2}} d^{\frac{1}{2}} \quad (79)$$

$$S_b = \sqrt{2} \left( \left( \frac{L_a^2 + L_v^2}{\mu} \right) d^2 + 1 \right)^{\frac{1}{2}} \quad (80)$$

$$L = \sqrt{2} C_\xi S_b \left( d \ln \left( 1 + \frac{2R_z}{\varepsilon_{\text{net}}} \right) + \ln \left( \frac{T}{\delta} \right) \right)^{\frac{1}{2}}. \quad (81)$$

Then

$$\mathbb{P} \left( \max_{0 \leq t \leq T-1} \|A_t v_t - v_{t+1}\|_2 \leq L + (\mu^{\frac{1}{2}} R + C_\xi d^{\frac{1}{2}} \sqrt{T}) \left( \frac{L_a^2 + L_v^2}{\mu} \right)^{\frac{1}{2}} d^{\frac{1}{2}} + 2C_\xi + C_\xi \right) \geq 1 - \delta. \quad (82)$$
The reason for the choice of values of $\varepsilon_{\text{net}}$, $R_z$, $S_b$, and $L$ can be seen in [102], [96], [98], and [105], respectively.

We note several lemmas we will need.

**Lemma D.2.** Let $v_s \in \mathbb{R}^d$ for $1 \leq s \leq t$. Suppose that $\sum_{s=1}^t v_s v_s^\top \preceq \Sigma$. Then

$$\sum_{s=1}^t v_s \Sigma^{-1} v_s \leq d. \quad (83)$$

**Proof.** We can choose $v'_s \in \mathbb{R}^d$, $1 \leq s \leq t'$ such that $\sum_{s=1}^t v_s v_s^\top + \sum_{s=1}^{t'} v'_s v'_s^\top = \Sigma$. Then

$$\sum_{s=1}^t v_s \Sigma^{-1} v_s + \sum_{s=1}^{t'} v'_s \Sigma^{-1} v'_s = \text{Tr} \left( \Sigma^{-1} \left( \sum_{s=1}^t v_s v_s^\top + \sum_{s=1}^{t'} v'_s v'_s^\top \right) \right) = \text{Tr}(I_d) = d \quad (84)$$

$$\implies \sum_{s=1}^t v_s \Sigma^{-1} v_s = d - \sum_{s=1}^{t'} v'_s \Sigma^{-1} v'_s \leq d. \quad (85)$$

**Lemma D.3** ([Ver10], Lemma 5.2). There is an $\varepsilon$-net of $B_1^d$ of size $(1 + \frac{2}{\varepsilon})^d$.

**Lemma D.4** (Generalization of Azuma’s Inequality [Sim+18, Lemma 4.2]). Let $\{F_t\}_{t \geq 0}$ be a filtration, and $\{Z_t\}_{t \geq 1}$ and $\{W_t\}_{t \geq 1}$ be real-valued processes adapted to $F_t$ and $F_{t+1}$ respectively. Moreover, assume $W_t | F_t$ is mean 0 and $\sigma^2$-sub-Gaussian. Then for any positive real numbers $L$ and $\beta$,

$$\mathbb{P} \left[ \left\{ \sum_{t=1}^T W_t Z_t \geq L \right\} \cap \left\{ \sum_{t=1}^T Z_t^2 \leq \beta \right\} \right] \leq \exp \left( -\frac{L^2}{2\sigma^2 \beta} \right)$$

**Proof of Lemma [D.4]** Let

$$\Sigma_t = \mu I_d + \sum_{s=0}^{t-1} v_s v_s^\top. \quad (86)$$

By Lemma B.3

$$A_t v_t - w_t = \sum_{s=0}^{t-1} (\varepsilon_{s+1} + \xi_{s+1}) v_s \Sigma_t^{-1} v_t - \mu \Sigma_t^{-1} v_t - \varepsilon_{t+1} - \xi_{t+1}. \quad (87)$$

**Bounding $\sum_{s=0}^{t-1} \xi_{s+1} v_s \Sigma_t^{-1} v_t$.** Let $b_s = v_s \Sigma_t^{-1} v_t$.

To use Azuma’s inequality, we need to bound the following. Using Cauchy-Schwarz ($\langle v, w \rangle^2 \leq \|v\|^2 \|w\|^2$),

$$\sum_{s=0}^{t-1} b_s^2 \leq \sum_{s=0}^{t-1} \left\| v_s \Sigma_t^{-\frac{1}{2}} \right\|^2 \left\| \Sigma_t^{-\frac{1}{2}} v_t \right\|^2 \quad (88)$$

$$= \left( \sum_{s=0}^{t-1} v_s \Sigma_t^{-1} v_s \right) \left\| \Sigma_t^{-\frac{1}{2}} v_t \right\|^2 \quad (89)$$

31
Choosing $a_s$ and $v$ as in (91),

$$\left\| \Sigma_t^{-\frac{1}{2}} v_t \right\|_2^2 = \left\| \Sigma_t^{-\frac{1}{2}} \left( \sum_{s=0}^{t-1} a_s v_s + v \right) \right\|_2^2 = \left\| \sum_{s=0}^{t-1} a_s \Sigma_t^{-\frac{1}{2}} v_s + \Sigma_t^{-\frac{1}{2}} v \right\|_2^2$$

$$\leq \left( \sum_{s=0}^{t-1} a_s^2 + \frac{\|v\|^2}{\mu} \right) \left( \sum_{s=0}^{t-1} \left\| \Sigma_t^{-\frac{1}{2}} v_s \right\|_2^2 + \frac{\mu}{\|v\|^2} \left\| \Sigma_t^{-\frac{1}{2}} v \right\|_2^2 \right)$$

by Cauchy-Schwarz (91)

$$\leq \left( \frac{L_a^2 + \frac{L_b^2}{\mu}}{\mu} \right) \left( \sum_{s=0}^{t-1} v_s^\top \Sigma_t^{-1} v_s + \frac{v^\top}{\|v\|} \Sigma_t^{-1} v \right).$$

(92)

Now $v_s v_s^\top + \mu \frac{w^w}{\|w\|^2} \leq \Sigma_t$ satisfies the hypothesis of Lemma D.2 so

$$\sum_{s=0}^{t-1} v_s^\top \Sigma_t^{-1} v_s + \frac{v^\top}{\|v\|} \Sigma_t^{-1} v \leq d$$

and so (92) gives

$$\left\| \Sigma_t^{-\frac{1}{2}} v_t \right\|_2^2 \leq \left( \frac{L_a^2 + \frac{L_b^2}{\mu}}{\mu} \right) d^2.$$ 

(94)

From (89), (93), and (94), we get

$$\sum_{s=0}^{t-1} b_s^2 \leq \left( \frac{L_a^2 + \frac{L_b^2}{\mu}}{\mu} \right) d^2.$$

(95)

Let $z_t = \Sigma_t^{-1} v_t$. By (92) and (93),

$$\|z_t\| = \left\| \Sigma_t^{-\frac{1}{2}} \right\|_2 \left\| \Sigma_t^{-\frac{1}{2}} v_t \right\|_2 \leq \mu^{-\frac{1}{2}} \left( \frac{L_a^2 + \frac{L_b^2}{\mu}}{\mu} \right)^{\frac{1}{2}} d^2 = R_z$$

(96)

so $z_t \in B^d_{R_z}$. By Lemma D.3 there is an $\varepsilon_{\text{net}}$-net $\mathcal{N}$ of $B^d_{R_z}$ of size $(1 + \frac{2R}{\varepsilon_{\text{net}}})^d$. Since $z_t \in B^d_{R_z}$, there exists $\|\Delta z\| \leq \varepsilon_{\text{net}}$ such that $z_t + \Delta z \in \mathcal{N}$. Note that

$$\sum_{s=0}^{t-1} \left| \sum_{s=0}^{t-1} |v_s^\top (z_t + \Delta z)|^2 \right| \leq 2 \left( \sum_{s=0}^{t-1} |v_s^\top z_t|^2 + |v_s^\top \Delta z|^2 \right) \leq 2 \left( \sum_{s=0}^{t-1} b_s^2 \right) + \sum_{s=0}^{t-1} g(s) \varepsilon_{\text{net}}^2$$

(97)

$$\leq 2 \left( \frac{L_a^2 + \frac{L_b^2}{\mu}}{\mu} \right) d^2 + 1 = S_b^2.$$ 

(98)

For a fixed $z$, consider the event $E_z = \{ \sum_{s=0}^{t-1} |y_s^\top z|^2 > S_b^2 \text{ or } \sum_{s=0}^{t-1} \xi_{s+1} y_s^\top z \leq L \}$. Then by the generalization of Azuma’s inequality D.4

$$\mathbb{P}(E_z^c) \leq \mathbb{P} \left( \sum_{s=0}^{t-1} |y_s^\top z|^2 \leq S_b^2 \text{ and } \sum_{s=0}^{t-1} \xi_{s+1} y_s^\top z > L \right) \leq \exp \left( -\frac{L^2}{2C^2 \xi^2 S_b^2} \right).$$

(99)

(100)
Now we use the triangle inequality to bound the sum by the maximum value on the $\varepsilon_{\text{net}}$-net.

\[
\left\| \sum_{s=0}^{t-1} \xi_{s+1} v_s^T z \right\| \leq \left\| \sum_{s=0}^{t-1} \xi_{s+1} v_s^T (z + \Delta z) \right\| + \left\| \sum_{s=0}^{t-1} \xi_{s+1} v_s^T (\Delta z) \right\| \tag{101}
\]

\[
\leq \max_{\sum_{s=0}^{t-1} |v_s^T z'|^2 \leq S_b^2} \left\| \sum_{s=0}^{t-1} \xi_{s+1} v_s^T z' \right\| + C \xi \sum_{s=0}^{t-1} g(s) \varepsilon_{\text{net}} \tag{102}
\]

\[
= \max_{\sum_{s=0}^{t-1} |v_s^T z'|^2 \leq S_b^2} \left\| \sum_{s=0}^{t-1} \xi_{s+1} v_s^T z' \right\| + C \xi \tag{103}
\]

Under the event $\bigcap_{z' \in N} E_{z'}$, we have that the maximum above is $\leq L$. Thus

\[
\Pr \left( \left\| \sum_{s=0}^{t-1} \xi_{s+1} v_s^T z \right\| > C_\xi + L \right) \leq \Pr \left( \bigcup_{z' \in N} E_{z'}^c \right) \tag{104}
\]

\[
\leq \left( 1 + \frac{2R_s}{\varepsilon_{\text{net}}} \right)^d \exp \left( - \frac{L^2}{2C_\xi^2 S_b^2} \right) \leq \frac{\varepsilon}{T}. \tag{105}
\]

by the choice of $L$.

**Bounding $\sum_{s=0}^{t-1} \varepsilon_{s+1} v_s^T \Sigma_t^{-1} v_t$.** A crude bound suffices here. We have by (95) that

\[
\sum_{s=0}^{t-1} \varepsilon_{s+1} v_s^T \Sigma_t^{-1} v_t \leq C_\varepsilon \sum_{s=0}^{t-1} |v_s^T (\Sigma_t)^{-1} v_t| \tag{106}
\]

\[
\leq C_\varepsilon \sqrt{T} \sqrt{\sum_{s=0}^{t-1} |v_s^T (\Sigma_t)^{-1} v_t|^2} \tag{107}
\]

\[
\leq C_\varepsilon \sqrt{T} \left( L_a^2 + \frac{L_b^2}{\mu} \right)^{\frac{1}{2}} d. \tag{108}
\]

**Bounding $\mu A \Sigma_t^{-1} v_t$.** We have by (96) that

\[
\left\| \mu A \Sigma_t^{-1} v_t \right\| \leq \mu A R_z = \mu \frac{1}{2} R \left( L_a^2 + \frac{L_b^2}{\mu} \right)^{\frac{1}{2}} d^{\frac{1}{2}} \tag{109}
\]

From (87), (105), (108), and (109), and noting that $\|\varepsilon_{t+1} + \xi_{t+1}\| \leq C_\xi + C_\varepsilon$, we get that

\[
\Pr \left( \| A_t v_t - w_t \| > L + (\mu \frac{1}{2} R + C_\varepsilon d^{\frac{1}{2}} \sqrt{T}) \left( L_a^2 + \frac{L_b^2}{\mu} \right)^{\frac{1}{2}} d^{\frac{1}{2}} + 2C_\xi + C_\varepsilon \right) \leq \frac{\varepsilon}{T}. \tag{110}
\]

Union-bounding over $0 \leq t \leq T - 1$ finishes the proof.
Proof of Theorem 4.4. We apply Lemma D.1 to the system (13). Let \( k' = [(d + m) \log_2(M) ] \) and \( C = C_A(C_B C_u + C_\xi) \). By (75) with \( p = 1 \), we can write \( x_t = \sum_{s=0}^{t} a_s x_s + v \) with \( \sum_{s=0}^{t} |a_s| \leq L_a \) and \( \|v\|_2 \leq L_v \), where

\[
L_a = \frac{2}{\ln 2}(d + m) \tag{111}
\]

\[
L_v = (k' + 1)^r \left( \frac{2}{\ln 2}(d + m)(C + 1) + C_0 + 2 \right) + C_u \left( \frac{2}{\ln 2} (d + m) + 2 \right) \tag{112}
\]

using (74) in the last step.

Then Lemma D.1 is satisfied with these values of \( L_a, L_v \), and (by Lemma C.12), \( g(t) = (t + 1)^{r-1} C_A C_0 + t^r C_A (C_B C_u + C_\xi) \). Defining \( \varepsilon, R_z, S_k, L \) as in Lemma D.1, we get that

\[
P \left( \max_{0 \leq t \leq T-1} \| A_t v_t - v_{t+1} \|_2 \leq L + \mu^2 \left( \frac{L_a}{\mu} + \frac{L_v}{\mu} \right) d + 2 C_\xi \right) \geq 1 - \varepsilon. \tag{113}
\]

Then with probability \( 1 - \varepsilon \), we have by Theorem 2.1 that

\[
R_T(A, B) \leq \mu R^2 + \left( L + \mu^2 \left( \frac{L_a}{\mu} + \frac{L_v}{\mu} \right) d + 2 C_\xi \right)^2 (d + m) d \ln \left( 1 + \frac{TM^2}{d} \right) \tag{114}
\]

where \( L_a, L_v, L, M \) have the desired parameter dependences; take \( \mu = 1 \).

\[\Box\]

E  Proof: Partially observable system, stochastic setting

E.1  Learning the steady-state Kalman filter

In the prediction problem, at each time step \( t \), we have observed \( y_0, \ldots, y_t \) and \( u_0, \ldots, u_t \), and are asked to predict \( y_{t+1} \). Note that this does not immediately fit in the framework for online least squares, because \( y_{t+1} \) is a linear function of the unobserved \( x_t \) (the latent state) plus noise. However, as we will see, we can still place it in this framework if we use an linear autoregressive estimator.

The Kalman filter \[\text{Kal60}, \text{KS99}\] gives the optimal linear estimator in the case that the parameters of the LDS, the noises, and the initial state are drawn from known Gaussian distributions, i.e. \( x_0 \sim N(x_0^-, \Sigma_0) \), \( \xi_t \sim N(0, \Sigma_x) \), \( \eta_t \sim N(0, \Sigma_y) \). We can compute matrices \( A_{KF}^{(t)}, B_{KF}^{(t)}, \) and \( C_{KF}^{(t)} \) such that the optimal linear estimate of the latent state \( \hat{x}_t \) and the observation \( \hat{y}_t \) are given by a time-varying LDS (taking the \( y_t \) as feedback) with those matrices :

\[
x_t^- = A_{KF}^{(t)} x_{t-1}^- + B_{KF}^{(t)} u_{t-1} \]
\[
\hat{y}_t = C_{KF}^{(t)} x_t^- . \tag{115}
\]

We will denote \( B_{KF} = (B_{KF,x} \, B_{KF,y}) \), where \( B_{KF,x} \) and \( B_{KF,y} \) are the submatrices acting on \( u_{t-1} \) and \( y_{t-1} \), respectively. In this case, \( x_t^- \) and \( \hat{y}_t \) are the maximum a posteriori (MAP) estimators, and the actual hidden state \( x_t \) and the observation \( y_t \) are Gaussians when conditioned on \( \mathcal{F}_{t-1} = \sigma(y_0, \ldots, y_{t-1}) \) (the observations up to time \( t - 1 \)):

\( x_t | \mathcal{F}_{t-1} \sim N(x_t^- , \Sigma_{KF,x}^{(t)}) \) and \( y_t | \mathcal{F}_{t-1} \sim N(y_t^- , \Sigma_{KF,y}^{(t)}) \).
$N(\tilde{y}_t, \Sigma_{KF,t}^{KF})$ for some covariance matrices $\Sigma_{KF,x}^{KF}, \Sigma_{KF,y}^{KF}$. Our goal is to predict as well as the Kalman filter without knowing the parameters of the original LDS.

If the original system is observable and the noise is i.i.d., taking $t \to \infty$, the matrices $A_{KF}^{(t)}, B_{KF}^{(t)}$, and $C_{KF}^{(t)}$ approach certain fixed matrices $A_{KF}, B_{KF},$ and $C_{KF}$, and the covariance matrices $\Sigma_{KF,x}^{(t)}$ and $\Sigma_{KF,y}^{(t)}$ approach fixed matrices $\Sigma_{KF,x}$ and $\Sigma_{KF,y}$ [Har97]. In the Gaussian case, at steady-state, the actual hidden state $x_t$ and observation $y_t$ will be distributed as $x_t|\mathcal{F}_{t-1} \sim N(x_t, \Sigma_x)$ and $y_t|\mathcal{F}_{t-1} \sim N(\tilde{y}_t, \Sigma_y)$. To simplify the problem, we will assume that the LDS starts with the steady-state covariance, so that the steady-state Kalman filter is the optimal filter for all time.

As before, our task is to predict $\tilde{y}_{t+1}$ at time step $t$. The regret is now defined by

$$R_T(A, B, C) = \mathbb{E} \left[ \sum_{t=0}^{T-1} \|\tilde{y}_{t+1} - y_{t+1}\|^2_2 - \sum_{t=0}^{T-1} \|\tilde{y}_{t+1,KF} - y_{t+1}\|^2_2 \right]$$

(117)

where $\tilde{y}_{t+1,KF}$ is the prediction given by (116). The challenge to competing with the Kalman filter prediction is that the Kalman filter has memory: its prediction depends on a state estimate $x_t$ kept in memory. We can remove this dependence by “unrolling” the Kalman filter and then truncating. Then we find that $\tilde{y}_{t+1,KF}$ is approximately a linear function of $u_{t-\ell+1}, \ldots, u_t$ and $y_{t-\ell+1}, \ldots, y_t$ for large enough $\ell$:

$$\tilde{y}_{t+1,KF} = Fu_{t-\ell+1} + Gy_{t-\ell+1}$$

where $F = (C_{KF}B_{KF,u}, C_{KF}A_{KF}B_{KF,u}, \ldots, C_{KF}A_{KF}^{d-1}B_{KF,u})$

and $G = (C_{KF}B_{KF,y}, C_{KF}A_{KF}B_{KF,y}, \ldots, C_{KF}A_{KF}^{d-1}B_{KF,y})$.

In other words, we can approximate the Kalman filter with an autoregressive filter of length $\ell$.

The framework of online least-squares (Algorithm 1) now applies with $x_t \leftarrow (u_{t-\ell+1}^t \ldots u_t), y_t \leftarrow y_{t+1}, A \leftarrow (F, G), n \leftarrow n, m \leftarrow \ell(d+m)$, giving Algorithm 3. We let $u_s = 0$ and $y_s = 0$ for $s < 0$.

**E.2 Norms and sufficient length**

First we define the sufficient length of a system. Roughly speaking, the sufficient length $R(\varepsilon)$ is the length at which we can truncate a finite impulse response (FIR) filter, so that when inputs are bounded by 1, we incur at most $\varepsilon$ prediction error at any time step. This notion was introduced by [Tu+17] in the one-dimensional setting.

We first recall some concepts from control theory. In particular, the definition of sufficient length depends on the $\mathcal{H}_\infty$ norm.

**Definition E.1.** Let $F$ be a stable, linear time-invariant (LTI) system, represented as the transfer function $F(z) = \sum_{j=0}^\infty F_j z^{-j} \in \mathbb{R}^{n\times m}[z^{-1}]$. (This is a matrix-valued Laurent series whose coefficients $(F_0, F_1, \ldots)$ form the impulse response function, that is, the response to input $v \in \mathbb{R}^m$ is $(F_0 v, F_1 v, \ldots)$.) Define the $\mathcal{H}_\infty$ norm of $F$ to be $\|F\|_{\mathcal{H}_\infty} := \max_{|\varepsilon|=1} \|F(\varepsilon)\|_2$.

\(^2\)Note that steady-state refers to the covariance of the $x_t|\mathcal{F}_{t-1}$ and $y_t|\mathcal{F}_{t-1}$ being constant, rather than the distribution of $x_t|\mathcal{F}_{t-1}$ and $y_t|\mathcal{F}_{t-1}$ being constant. If the system is not strictly stable, it does not have a steady state, because $x_t$ will diverge.
**Definition E.2** (Sufficient length condition, [Tu+17, Definition 1]). We say that a Laurent series (or LTI system) $F$ has stability radius $\rho \in (0, 1)$ if $F$ converges for $\{x \in \mathbb{C} : |x| > \rho\}$. Let $F$ be stable with stability radius $\rho \in (0, 1)$. Fix $\varepsilon > 0$. Define the sufficient length

$$R(\varepsilon) = \inf_{\rho < \gamma < 1} \frac{1}{1 - \gamma} \ln \left( \frac{\|F(\gamma z)\|_{\infty}}{\varepsilon(1 - \gamma)} \right).$$  

(118)

Note that having a dependence on sufficient length is analogous to having a dependence on the spectral radius of $A$, for learning a LDS. Roughly, if we ignore factors depending on condition numbers, for a LDS with dynamics given by $A$, the sufficient length $R(\varepsilon)$ is on the order of $O\left(\frac{1}{1 - \rho(A)} \cdot \ln \left(\frac{1}{\varepsilon}\right)\right)$.

The following lemma says that if we are content with an error of $\varepsilon$, we can safely truncate the impulse response function at length $R(\varepsilon)$. Note that [Tu+17] give the proof for the one-dimensional case, but the same proof works in the multi-dimensional setting.

**Lemma E.3** ([Tu+17, Lemma 4.1]). Suppose $F$ is stable with stability radius $\rho \in (0, 1)$. Then $\|F_{\geq L}\|_1 := \sum_{k \geq L} \|F(k)\| \leq \max_{\rho < \gamma < 1} \frac{\|F(\gamma z)\|_{\infty}}{1 - \gamma}$. Hence, if $L \geq R(\varepsilon)$, then $\|F_{\geq L}\|_1 \leq \varepsilon$.

If the LDS is not stable, then we cannot truncate the dependence on past inputs. The key observation due to [Koz+19] is that even if the original LDS is not stable, the LDS defined by the Kalman filter is stable. Hence, there is some sufficient length at which we can truncate the unrolled Kalman filter.

**Theorem E.4** ([Koz+19]). When the LDS (2)–(3) is observable, and the noise is i.i.d. Gaussian, the associated Kalman filter (as defined in Section 2.3) is strictly stable: $\rho(A_{KF}) < 1$.

**E.3 Proof of Theorem 4.6**

**Proof of Theorem 4.6.** We first condition on all the noise terms $\|\xi_t\| \leq \|\Sigma_x\| O\left(\sqrt{d \ln \left(\frac{1}{\delta}\right)}\right) =: C_{\xi}$, $\|\eta_t\| \leq \|\Sigma_y\| O\left(\sqrt{n \ln \left(\frac{1}{\delta}\right)}\right) =: C_{\eta}$. Choosing the constants large enough, we can ensure this happens with probability $\geq 1 - \frac{\delta}{3}$.

Let $v_t = (h_t; \ldots; h_{t-\ell+1}; u_t; \ldots; u_{t-\ell+1})$ For convenience set $h_t = 0, u_t = 0$ for $t < 0$. Then $(v'_t)_{t=0}^{\infty}$ satisfies the following:

$$v'_t = A'v'_{t-1} + \xi'_t$$  

(119)

$$A' = \begin{pmatrix} A & 0 & \cdots & 0 \\ I & O & \cdots & 0 \\ \vdots & \ddots & \ddots & \vdots \\ I & O & \cdots & 0 \\ B & O & \cdots & O \\ O & I & \cdots & 0 \\ \vdots & \ddots & \ddots & \vdots \\ O & \cdots & I & O \\ O & \cdots & O & I \end{pmatrix}$$  

(120)
\[
v'_t = \begin{pmatrix} h_0 \\ 0 \\ u_0 \\ 0 \end{pmatrix} \in K'_0 := B^d_{C_0} \oplus \{0\}^{(\ell-1)d} \oplus B^m_{C_u} \oplus \{0\}^{(\ell-1)m}
\]

\[
\epsilon'_t = \begin{pmatrix} \xi_t \\ 0 \\ u_t \\ 0 \end{pmatrix} \in K' := B^d_{C_z} \oplus \{0\}^{(\ell-1)d} \oplus B^m_{C_u} \oplus \{0\}^{(\ell-1)m}.
\]

If \( h_0 = h, u_0 = u, \) and \( u_t = 0 \) for \( t \geq 1, \) and there is no noise, then \( h_t = A^t h + A^{t-1} Bu \) for \( t \geq 1. \) Hence

\[
\left\| (A')^{k'} \begin{pmatrix} h \\ 0 \\ u \\ 0 \end{pmatrix} \right\|_2 \leq \sqrt{\ell} \left[ \max_{0 \leq k \leq k'} f_A(k) \|h\| + \left( \max_{0 \leq k \leq k'-1} f_A(k) C_B + 1 \right) \|u\| \right].
\]

(123)

Note also that

\[
\max_{v \in B_{A}^{d+m}} \left\| (A')^{k'} v \right\| = \max_{(h;u) \in B_{A}^{d+m}} \left\| (A')^{k'} \begin{pmatrix} h \\ 0 \\ u \\ 0 \end{pmatrix} \right\|
\]

(124)
because we can check that

\[
\left\| (A')^{k'} \begin{pmatrix} h_{\ell-1} \\ \vdots \\ h_0 \\ u_{\ell-1} \\ \vdots \\ u_0 \end{pmatrix} \right\| \leq \left\| (A')^{k'} \begin{pmatrix} \frac{h_{\ell-1}}{\|h_{\ell-1}\|} & h_{\ell-1} \\ \vdots \\ \frac{u_{\ell-1}}{\|u_{\ell-1}\|} & u_{\ell-1} \\ 0 & 0 \end{pmatrix} \right\|
\]

We will apply Lemma \( \text{C.5} \). Let \( k' = \lfloor \ell (d + m) \log_2 (M) \rfloor \) and \( C' = C_A C_0 + C_A C_B C_u + C_u. \) We bound (23). By (123), (124), and Lemma \( \text{C.9} \)

\[
f_{A',K'_0 \cup B_{A}^{d+m}}^{(d+m)}(k) = \sqrt{\ell} \left[ \max_{0 \leq k \leq k'} f_A(k) \left( C_0 + \frac{2}{\ln 2} \ell (d + m) \right) \\
+ \left( \max_{0 \leq k \leq k'-1} f_A(k) + 1 \right) \left( C_u + \frac{2}{\ln 2} \ell (d + m) \right) \right] \leq \sqrt{\ell} \left[ C_A (k' + 1)^{r-1} \left( C_0 + \frac{2}{\ln 2} \ell (d + m) \right) \\
+ (C_A C_B (k')^{r-1} + 1) \left( C_u + \frac{2}{\ln 2} \ell (d + m) \right) \right] \leq \sqrt{\ell} \left[ C' (k' + 1)^{r-1} + (C_A (C_B + 1) + 1) \frac{2}{\ln 2} \ell (d + m) \right]
\]

37
\[
\sum_{k=0}^{k-1} f_{A',K'}(k) \leq \sqrt{t} \left[ \sum_{k=0}^{k-1} \max_{0 \leq j \leq k} f_A(k)C_\xi + \left( \sum_{k=0}^{k-2} \max_{0 \leq j \leq k} f_A(k)C_B + 1 \right) C_u \right] \\
\leq \sqrt{t}[(k')^rC_\xi + ((k' - 1)^rC_B + 1)C_u].
\]

By Lemma [C.5] for \(0 \leq t \leq T\), there exist \(a_s \in \mathbb{R}\) and \(v \in \mathbb{R}^{\ell(d+m)}\) such that \(v_t = \sum_{s=0}^{t-1} a_s v_s + v\) with

\[
\sum_{t=0}^{T-1} |a_t| \leq \frac{2}{\ln 2} \ell(d + m) =: L_v
\]

\[
\|v\| \leq \max_{0 \leq k \leq k'} f_{A',K'}(k') \left( k' \right) + \left( \sum_{k=0}^{k-1} f_{A',K'}(k) \right) \left( \frac{2}{\ln 2} \ell(d + m) + 1 \right)
\]

\[
= \sqrt{t} \left[ C'(k' + 1)^{r-1} + (C_A(C_B + 1) + 1 + (k')^rC_\xi + ((k' - 1)^rC_B + 1)C_u \right] \left( \frac{2}{\ln 2} \ell(d + m) + 1 \right) =: L_v.
\]

Now let \(v_t = (y_t; \cdots; y_{t-\ell+1}; u_t; \cdots; u_{t-\ell+1})\). Then

\[
v_t = C'v_t' + \begin{pmatrix} \eta_{t: t-\ell+1} \\ 0 \end{pmatrix}
\]

where

\[
C' = \begin{pmatrix} I_\ell \otimes C & O \\ O & I_{\ell m} \end{pmatrix}.
\]

Now if \(v_t' = \sum_{s=0}^{t-1} a_s v_s' + v\) with \(\sum_{s=0}^{t-1} a_s \leq L_a\) and \(\|v\| \leq L_v\), then

\[
C'v_t' = \sum_{s=0}^{t-1} a_s C'v_s' + C'v
\]

\[
\implies v_t - \begin{pmatrix} \eta_{t: t-\ell+1} \\ 0 \end{pmatrix} = \sum_{s=0}^{t-1} a_s \left( v_s - \begin{pmatrix} \eta_{s:s-\ell+1} \\ 0 \end{pmatrix} \right) + C'v
\]

\[
\implies v_t = \sum_{s=0}^{t-1} a_s v_s + \begin{pmatrix} \eta_{s:s-\ell+1} \\ 0 \end{pmatrix} - \sum_{s=0}^{t-1} a_s \begin{pmatrix} \eta_{s:s-\ell+1} \\ 0 \end{pmatrix} + C'v
\]

so it can be written as a linear combination of previous \(v_s\)'s with

\[
L_a = L_a'
\]

\[
L_v = CCL_v' + (L_a + 1)\sqrt{t}C_{\eta}
\]

If \(x_0 \sim N(0, \Sigma_{KF,x})\), then \(x_0 = 0\), the steady-state Kalman filter applies, and unfolding the Kalman filter recurrence gives

\[
y_{t+1} = \sum_{s=0}^{t} F_s u_{t-s} + \sum_{s=0}^{t} G_s y_{t-s} + C_{KF} A_{KF}^{t+1} x_0 + \zeta_+ = \sum_{s=0}^{t} F_s u_{t-s} + \sum_{s=0}^{t} G_s y_{t-s} + C_{KF} A_{KF}^{t+1} x_0 + \zeta_+
\]

38
where \( \zeta_{t+1} | \mathcal{F}_t \sim N(0, \Sigma_{KF,y}) \) is \( \| \Sigma_{KF,y} \|^2 \)-subgaussian. Then \((y_t)\) satisfies Lemma \[D.1\] with \( L_a, L_v \), and with \( w_t = y_{t+1} \) where

\[
y_{t+1} = (F, G) \begin{pmatrix} u_{t:t-\ell+1} \\ y_{t:t-\ell+1} \end{pmatrix} + \varepsilon_{t+1} + \zeta_{t+1}
\]
\[
\varepsilon_{t+1} = \sum_{s=\ell}^{t} (F_s u_{t-s} + G_s y_{t-s}).
\]

By Lemma \[C.12\]
\[
\max_{0 \leq s \leq t-\ell} \max \{ \| u_t \|, \| y_t \| \} \leq T^\nu C_C C_A (C_B C_u + C_\xi) =: K.
\]

By choice of \( \ell = R(\varepsilon') \), where \( \varepsilon' = \frac{\varepsilon}{K} \), we get
\[
\| \varepsilon_{t+1} \| = \left\| \sum_{s=\ell}^{t} (F_s u_{t-s} + G_s y_{t-s}) \right\| \leq \varepsilon' \max_{0 \leq s \leq t-\ell} \max \{ \| u_t \|, \| y_t \| \} \leq \varepsilon.
\]

We also know \( \xi_{t+1} | \mathcal{F}_t \sim N(0, \Sigma_{KF,y}) \). Apply Lemma \[D.1\] to get a polynomial bound on \( \max_{0 \leq t \leq T-1} \| F_t u_{t:t-\ell+1} + G_t y_{t:t-\ell+1} - y_{t+1} \| \) and Theorem \[2.1\] to finish.
