Abstract

Background: A Family Day program was implemented at Indiana University School of Medicine to educate the families and friends of in-coming medical students about the rigors of medical school and the factors that contribute to stress.

Methods: Surveys that assessed knowledge, beliefs, and attitudes about medical school were administered to participants before and after the program.

Results: After the program, participants showed a significant improvement in their understanding of medical school culture and the importance of support systems for medical students. Post-test scores improved by an average of 29% (P < 0.001) in each of the two years this program was administered.

Conclusions: The inclusion of family members and other loved ones in pre-matriculation educational programs may serve to mitigate the stress associated with medical school by enhancing the students’ social support systems.

Background

The significant stress experienced by both undergraduate and graduate medical trainees is well documented. In a recent literature review, Shapiro et al. [1] identified over 600 articles that discussed the importance of addressing the stress of medical education. As many as one-third of medical students suffer from psychological morbidity [2,3]. Examples of stressors facing students include the need to demonstrate competence, both academic and clinical; managing financial pressures and transitional issues; coping with depression and feelings of isolation; dealing with issues of life and death; making career specialty decisions; and balancing school pressures with family and social obligations.

Regarding this later aspect, Rappaport et al. [4] studied the effects of a general surgery residency on the spouses and children of graduate trainees. These investigators found that, at least in their residency program, the stress of medical training created significant problems for the families, further exacerbating an already difficult period. This finding underscores the important relationship between the medical trainee and his or her loved ones. Not all medical students will be married, of course, but most will have close relationships with parents, siblings, or other intimates with whom they confide and draw support. Because family members and close friends provide core social support, they are logical targets for pre-matriculation educational programs aimed at reducing stress in medical
The second program was conducted in fall 2001. Based on feedback from the previous year, the number of topics was reduced to allow more thorough coverage of the curriculum, the competencies, and the residency match. Financial aid and career specialty information was provided in handout format. The survey instrument was modified accordingly.

Pre- and post-program surveys that assessed knowledge, beliefs, and attitudes about medical school were administered to the participants of the 2000 and 2001 programs (Additional file: 1). Question topics included the nature and structure of medical school, the psychosocial stressors most often experienced by medical students, residency procurement and length of graduate training, indebtedness and earnings potential, and other relevant information. Pre- and post-program responses were compared with the unpaired t-test. Differences were considered statistically significant if p < 0.05.

**Results**

Sixty-two people attended the 2000 program and 65 attended the 2001 program. Pre- and post-program surveys were completed by 49 of the participants in 2000 and by 45 of the participants in 2001. To what extent these responders may have differed from the non-responders is not known. Participants in both 2000 (n = 49) and 2001 (n = 45) included medical students, their parents, spouses, fiancés/fiancées, relatives, and friends. In 2000, 52% of the participants were female and 48% male; participants in 2001 were 60% female and 40% male. In both years, 22% of the participants were in-coming medical students and 78% were family members and close friends. The occupations of these non-student participants included banking, sales, nursing, law, higher education, trucking, social work, and urban planning, among others.

After the program, participants demonstrated a significant increase in their knowledge of medical school culture and the demands placed on medical students (Table 1). Although the baseline pretest score in 2001 was somewhat higher than the pretest score in 2000, presumably because of changes in the survey questions, the percent improvement in post-test scores was essentially the same in both years. Survey scores increased by an average of 29.6% in 2000 (p < 0.001) and by 29.2% in 2001 (p < 0.001).

**Discussion**

These results suggest that we succeeded in educating participants about some of the stressors facing students and that we equipped participants with strategies for providing support. Written comments from the participants (both families and students) suggest that an unmet need had been fulfilled. Comments included: "Absolutely
great! Very informative and certainly worth the time. I would recommend it to every student and his/her family to attend”; “I enjoyed this very much, especially the validation of feeling somewhat isolated from your spouse (the student) and now understanding why”; “Very enlightening!”; “Very informative!”; “Learned a lot”; and “Should continue this program.”

However, it is not known whether the improvements we noted in the survey scores presage improvements in long-term outcomes. A comparison with a matched cohort of students and support system members who did not participate in the program would be helpful. Following such cohorts over time could help determine if there were lasting differences between the groups. Of course, any such analysis would be subject to the bias of participant self-selection. That is, students and support system members who elect to participate in the program may already be sensitized to the need for effective stress management. Nevertheless, outcome measures that might be followed include attrition rates, leaves of absence, academic performance, and overall satisfaction with medical school.

Conclusions
Stress during medical school is common. Accordingly, efforts to develop multiple stress-management techniques should continue. We have shown that a pre-matriculation educational program aimed at the families and friends of in-coming medical students can improve their understanding of medical school, which may help to mitigate the stress experienced by medical students by reinforcing the students’ social support.
