SPECIAL VALUES OF HYPERGEOMETRIC FUNCTIONS AND PERIODS OF CM ELLIPTIC CURVES

YIFAN YANG

ABSTRACT. Let $X_{60}^0(1)/W_6$ be the Atkin-Lehner quotient of the Shimura curve $X_{60}^0(1)$ associated to a maximal order in an indefinite quaternion algebra of discriminant 6 over $\mathbb{Q}$. By realizing modular forms on $X_{60}^0(1)/W_6$ in two ways, one in terms of hypergeometric functions and the other in terms of Borcherds forms, and using Schofer's formula for values of Borcherds forms at CM-points, we obtain special values of certain hypergeometric functions in terms of periods of elliptic curves over $\mathbb{Q}$ with complex multiplication.

1. INTRODUCTION

Let $X_D^0(N)$ be the Shimura curve associated to an Eichler order of level $N$ in an indefinite quaternion algebra of discriminant $D$ over $\mathbb{Q}$. When $D = 1$, the Shimura curve $X_D^0(N)$ is just the classical modular curve $X^0(N)$ and there are many different constructions of modular forms on $X_0(N)$ in literature, such as Eisenstein series, Dedekind eta functions, Poincare series, theta series, and etc. These explicit constructions provide practical tools for solving problems related to classical modular curves. On the other hand, when $D \neq 1$, because of the lack of cusps, most of the methods for classical modular curves cannot possibly be extended to the case of general Shimura curves. As a result, even some of the most fundamental problems about Shimura curves, such as finding equations of Shimura curves, computing Hecke operators on explicitly given modular forms, and etc., are not easy to answer. However, in recent years, there have been two realizations of modular forms on Shimura curve emerging in literature and some progress toward the study of Shimura curves has already been made using these two methods.

The first method was due to the author of the present paper. In [36], we first observed that when a Shimura curve $X$ has genus 0, all modular forms on $X$ can be expressed in terms of solutions of the Schwarzian differential equation associated to a Hauptmodul of $X$. Then by utilizing the Jacquet-Langlands correspondence and explicit covers between Shimura curves, we devised a method to compute Hecke operators with respect to the explicitly given basis of modular forms. As applications of this computation of Hecke operators, we computed modular equations for Shimura curves, which can be regarded as equations for Shimura curves associated to Eichler orders of higher levels, in [34] and obtained Ramanujan-type identities for Shimura curves in [35]. In addition, since some Schwarzian differential equations are essentially hypergeometric differential equations, this realization of modular forms yields many beautiful identities among hypergeometric functions. This is discussed in [29][31].
The second method is to realize meromorphic modular forms with divisors supported on CM-points as Borcherds forms associated to the lattice formed by the elements of trace zero in an Eichler order. Borcherds forms themselves are not easy to work with. What makes Borcherds forms useful in practice is Schofer’s formula [24] for norms of (generalized) singular moduli of Borcherds forms, that is, norms of values of Borcherds forms at CM-points. Schofer’s formula is based on an earlier work of Kudla [19], and the evaluation of derivatives of Fourier coefficients of Eisenstein series uses works of Kudla, Rapoport, and Yang [20, 22, 23]. An immediate consequence of Schofer’s formula is a necessary condition for primes that can appear in the prime factorization of the norm of the difference of two singular moduli of different discriminants, which is analogous to Gross-Zagier’s work [16] for the case of the classical modular curve $X_0(1)$. Also, Errthum [13] used Schofer’s formula to determine singular moduli of $X_0^6(1)/W_6$ and $X_{10}^6(1)/W_{10}$, where $W_D$ denotes the group of all Atkin-Lehner involutions on $X_D^6(1)$, verifying Elkies’ numerical computation [12]. (However, we remark that Schofer’s formula needs a slight correction when the Borcherds forms have nonzero weights. See Section 4 below.)

The realization of modular forms on Shimura curves in [36] is completely analytic, while Schofer’s formula for singular moduli of Borcherds forms is more arithmetic in nature. (For example, the primary motivation of [19, 20, 21, 22] was to obtain arithmetic Siegel-Weil formulas realizing generating series from arithmetic geometry as modular forms.) It is an interesting problem to see what results we can obtain by combining the two approaches. This is the main motivation of the present work.

In this paper, we will consider the Shimura curve $X = X_0^6(1)/W_6$. From [36], we know that every holomorphic modular form on $X$ can be expressed in terms of hypergeometric functions. Now according to [26, Theorem 7.1] and [37, Theorem 1.2 and (1.4) of Chapter 3], if $t(\tau)$ is a modular function on $X$ that takes algebraic values at all CM-points, then the value of $t'(/) at a CM-point of discriminant $d$ is an algebraic multiple of the square of

$$\omega_d = e^{L'(0,\chi_d)/2L(0,\chi_d)} = \frac{1}{\sqrt{|d_0|}} \prod_{\alpha=1}^{\frac{|d_0|-1}{2}} \Gamma \left( \frac{\alpha}{|d_0|} \right) \chi_d(a) h_{d_0}/4h_{d_0},$$

where $d_0$ is the discriminant of the field $\mathbb{Q}(\sqrt{d})$, $\chi_d$ is the Kronecker character associated to $\mathbb{Q}(\sqrt{d})$, $h_{d_0}$ is the number of roots of unity in $\mathbb{Q}(\sqrt{d})$, and $h_{d_0}$ is the class number of $\mathbb{Q}(\sqrt{d})$. (See [2, Theorem 1.2] for some examples.) The significance of these numbers $\omega_d$ is that periods of any elliptic curve over $\mathbb{Q}$ with CM by $\mathbb{Q}(\sqrt{d})$ lie in $\sqrt{\omega_d} \cdot \mathbb{Q}$. (See [12, 25].) In other words, the values of certain hypergeometric functions at singular moduli can be expressed in terms of periods of CM elliptic curves over $\mathbb{Q}$.

**Theorem 1.** Let $s(\tau)$ be the Hauptmodul of $X_0^6(1)/W_6$ that takes values $0$, $1$, and $\infty$ at the CM-points of discriminants $-4$, $-24$, and $-3$, respectively. Let $\tau_d$ be a CM-point of discriminant $d$ such that $|s(\tau_d)| < 1$. Then

$$2F1 \left( \frac{1}{24}, \frac{5}{24}; \frac{1}{4}; s(\tau_d) \right) \in \frac{\omega_d}{\omega_{-4}} \cdot \mathbb{Q}, \quad 3F2 \left( 1, 1, 1; 2, 2, \frac{3}{4}; 5, \frac{1}{4}; s(\tau_d) \right) \in \omega_d^2 \cdot \mathbb{Q}. \quad \text{(1)}$$

Likewise, let $t(\tau) = 1/s(\tau)$. If $\tau_d$ is a CM-point of discriminant $d$ such that $|t(\tau_d)| < 1$, then

$$2F1 \left( \frac{1}{24}, \frac{7}{24}; \frac{5}{6}; t(\tau_d) \right) \in \frac{\omega_d}{\omega_{-3}} \cdot \mathbb{Q}, \quad 3F2 \left( 1, 1, \frac{1}{2}; 2, \frac{3}{4}, \frac{3}{6}; 7, \frac{7}{6}; t(\tau_d) \right) \in \omega_d^2 \cdot \mathbb{Q}. \quad \text{(2)}$$

The proof of the theorem will be given at the end of Section 2.
The parallel results in the cases of classical modular curves can be described as follows. Let \( \lambda_1 \) and \( \lambda_2 \) be a basis for a lattice \( \Lambda \) in \( \mathbb{C} \) with \( \text{Im}(\lambda_2/\lambda_1) > 0 \), and for positive even integers \( k \geq 4 \), let

\[
G_k(\Lambda) = \sum_{\lambda \in \Lambda, \lambda \neq 0} \frac{1}{\lambda^k}.
\]

Then Weierstrass’s equation for the elliptic curve \( \mathbb{C}/\Lambda \) over \( \mathbb{C} \) is

\[
y^2 = 4x^3 - 40G_4(\Lambda)x - 140G_6(\Lambda).
\]

From the relations

\[
G_4(\Lambda) = \frac{1}{45} (\pi \lambda_1)^4 E_4(\tau), \quad G_6(\Lambda) = \frac{2}{945} (\pi \lambda_1)^6 E_6(\tau),
\]

where \( \tau = \lambda_2/\lambda_1 \) and \( E_k \) are the normalized Eisenstein series of weight \( k \), we immediately see that for \( \tau \in \mathbb{Q}(\sqrt{d}) \cap \mathbb{H}^+ \),

\[
E_k(\tau) \in \left( \frac{\Omega_d}{\pi} \right)^k \mathbb{Q},
\]

where \( \Omega_d \) is any nonzero period of any elliptic curve over \( \mathbb{Q} \) with CM by \( \mathbb{Q}(\sqrt{d}) \). According to the Chowla-Selberg formula [14, 25], we may choose

\[
\Omega_d = \sqrt{\pi} \prod_{a=1}^{\lfloor |d|/2 \rfloor} \Gamma\left( \frac{a}{|d|} \right)^{\chi_d(a)p_d/4h_d} = \sqrt{\pi |d| \omega_d}.
\]

Now from the classical identity

\[
E_4(\tau) = 2F_1 \left( \frac{1}{12}, \frac{5}{12}; 1; \frac{1728}{j(\tau)} \right)^4,
\]

we conclude that if \( \tau \in \mathbb{Q}(\sqrt{d}) \cap \mathbb{H}^+ \), then

\[
2F_1 \left( \frac{1}{12}, \frac{5}{12}; 1; \frac{1728}{j(\tau)} \right) \in \frac{\Omega_d}{\pi} \mathbb{Q}.
\]

For instance, for \( \tau = i \), we have \( j(i) = 1728 \), and Gauss’ formula for values of hypergeometric functions at 1 and the multiplication formula for the Gamma function yield

\[
2F_1 \left( \frac{1}{12}, \frac{5}{12}; 1; \frac{1728}{j(\tau)} \right) = \frac{\Gamma(1/2)}{\Gamma(1/12)\Gamma(7/12)} = \frac{\sqrt{\pi} \Gamma(3/12)}{\Gamma(11/12)\Gamma(7/12)\Gamma(3/12)} = \frac{\sqrt{\pi} \Gamma(1/4)}{(2\pi)^{3/2} \Gamma(3/4)} = \frac{3^{1/4} \Omega_{-4}}{2 \pi}.
\]

For a fundamental discriminant \( d < 0 \), one may use the Chowla-Selberg formula [25, Page 110]

\[
\prod_{j=1}^{h_d} a_j^{-6} \Delta(\tau_j) = \frac{\omega_d^{12h_d}}{(2\pi)^{6h_d}},
\]

where the product runs through the complete set of reduced primitive quadratic forms \( a_jx^2 + b_jxy + c_jy^2 \) of discriminant \( d \) with \( \tau_j = (-b_j + \sqrt{d})/2a_j \), and its generalizations to determine special values of hypergeometric functions. See [14, 4, 11] for some examples.

Now to determine the precise values of the hypergeometric functions in Theorem 1 at singular moduli, we shall realize the modular forms involved as Borcherds forms. Then evaluating these modular forms at CM-points using Schofer’s formula, we obtain formulas...
for special values of hypergeometric functions. The results in the cases where there exists exactly one CM-point of fundamental discriminant $d$ are given in the next theorem. In Section 6, we will work out an example to illustrate a general technique to determine special values of the hypergeometric functions when there are more than one CM-points of discriminant $d$.

**Theorem 2.** The evaluations

\[
\begin{align*}
2F_1 \left( \frac{1}{24}, \frac{5}{24}; \frac{3}{4}; \frac{M}{N} \right) &= A_1 \frac{\omega_d}{\omega_{-4}}, \\
3F_2 \left( \frac{1}{3}, \frac{1}{2}, \frac{3}{4}; \frac{5}{4}; \frac{M}{N} \right) &= A_2 \omega_d^2
\end{align*}
\]

hold for

| $d$  | $M$   | $N$    | $A_1$  | $A_2$  |
|------|-------|--------|--------|--------|
| $-120$ | $-7^4$ | $3^3 \cdot 5^3$ | $\frac{1}{2} \sqrt{45} \sqrt{12 + 2\sqrt{30}}$ | $\frac{45}{7}$ |
| $-52$ | $2^4 \cdot 3^7$ | $5^6$ | $\frac{1}{2} \sqrt{5} \sqrt{8 + 2\sqrt{13}}$ | $\frac{25}{6}$ |
| $-132$ | $2^4 \cdot 11^2$ | $5^6$ | $\frac{1}{2} \sqrt{125} \sqrt{12 + 2\sqrt{33}}$ | $\frac{65}{22}$ |
| $-43$ | $-3^7 \cdot 7^4$ | $2^{10} \cdot 5^6$ | $\frac{1}{2} \sqrt{10} \sqrt{7 + 4\sqrt{3}}$ | $\frac{100}{21}$ |
| $-88$ | $3^7 \cdot 7^4$ | $5^6 \cdot 11^3$ | $\frac{1}{2} \sqrt{275} \sqrt{10 + 2\sqrt{22}}$ | $\frac{275}{21}$ |
| $-312$ | $7^4 \cdot 23^4$ | $5^6 \cdot 11^6$ | $\frac{1}{2} \sqrt{3} \sqrt{55} \sqrt{18 + 2\sqrt{78}}$ | $\frac{9075}{161\sqrt{2}}$ |
| $-148$ | $2^2 \cdot 3^7 \cdot 7^4 \cdot 11^4$ | $5^6 \cdot 17^6$ | $\frac{1}{2} \sqrt{85} \sqrt{14 + 2\sqrt{37}}$ | $\frac{7225}{217}$ |
| $-232$ | $-3^7 \cdot 7^4 \cdot 11^4 \cdot 19^4$ | $5^6 \cdot 23^6 \cdot 29^3$ | $\frac{1}{2} \sqrt{29} \sqrt{115} \sqrt{16 + 2\sqrt{58}}$ | $\frac{383525}{4389}$ |
| $-708$ | $2^8 \cdot 7^4 \cdot 11^4 \cdot 47^4 \cdot 59^2$ | $5^6 \cdot 17^6 \cdot 29^6$ | $\frac{1}{2} \sqrt{3} \sqrt{2465} \sqrt{30 + 2\sqrt{177}}$ | $\frac{18228675}{3619\sqrt{718}}$ |
| $-163$ | $-3^{11} \cdot 7^4 \cdot 19^4 \cdot 23^4$ | $2^{10} \cdot 5^6 \cdot 11^6 \cdot 17^6$ | $\frac{1}{2} \sqrt{1870} \sqrt{13 + \sqrt{163}}$ | $\frac{3496900}{27531}$ |

Also,

\[
\begin{align*}
2F_1 \left( \frac{1}{24}, \frac{7}{24}; \frac{5}{6}; \frac{M}{N} \right) &= B_1 \frac{\omega_d}{\omega_{-3}}, \\
3F_2 \left( \frac{1}{4}, \frac{1}{2}, \frac{3}{4}; \frac{7}{6}; \frac{M}{N} \right) &= B_2 \omega_d^2
\end{align*}
\]
hold for

\[
\begin{array}{|c|c|c|c|c|c|}
\hline
\vspace{2mm}
d & M & N & B_1 & B_2 \\
\hline
-84 & 3^3 & 2^2 \cdot 7^2 & \sqrt[3]{56} \sqrt{3 + \sqrt{3}} & 2^{14} \sqrt{3} \\
-40 & -5^3 & 3^7 & 12 \sqrt[3]{13} \sqrt{2 + \sqrt{10}} & 6 \sqrt{13} \\

-19 & -2^{10} & 3^7 & 12 \sqrt[3]{13} \sqrt{2 + \sqrt{19}} & 6 \sqrt{7} \\
-168 & 5^6 & 7^2 \cdot 11^4 & \sqrt[3]{22} \sqrt{4 + \sqrt{14}} & 2^{22} \sqrt{7} \\
-228 & -3^6 \cdot 5^6 & 2^6 \cdot 7^4 \cdot 19^2 & \sqrt[3]{62} \sqrt{28 + \sqrt{19}} & 2^{28} \sqrt{114} \\
-123 & 2^{10} \cdot 5^6 & 7^4 \cdot 19^4 & 12 \sqrt[3]{13} \sqrt{14 + 2 \sqrt{41}} & 133 \sqrt{20} \\
-67 & -2^{16} \cdot 5^6 & 3^7 \cdot 7^4 \cdot 11^4 & 12 \sqrt[3]{77} \sqrt{5 + \sqrt{67}} & 100 \sqrt{17} \\
-372 & 3^3 \cdot 5^6 \cdot 11^6 & 2^2 \cdot 7^4 \cdot 19^4 \cdot 31^2 & \sqrt[3]{62} \sqrt{266 + \sqrt{31}} & 2^{266} \sqrt{186} \\
-408 & 3^6 \cdot 5^6 \cdot 17^3 & 7^4 \cdot 11^4 \cdot 31^4 & \sqrt[3]{774} \sqrt{6 + \sqrt{34}} & 15 \sqrt{17} \\
-267 & 2^{16} \cdot 5^6 \cdot 11^6 & 7^4 \cdot 31^4 \cdot 43^4 & 12 \sqrt[3]{9331} \sqrt{22 + 2 \sqrt{89}} & 15 \sqrt{110} \\
\hline
\end{array}
\]

Remark 1. Let $F_1(s) = 2F_1(1/24, 5/24; 3/4; s)$, $G_1(t) = 2F_1(1/24, 7/24; 5/6; t)$, and

\[
F_2(s) = 2F_1(7/24, 11/24; 5/4; s) = 3F_2(1/3, 1/2, 2/3; 3/4; 5/4; s)/F_1(s)
\]

be the hypergeometric functions in Theorem 2. The Ramanujan-type identities obtained in [35] can be written as

\[
\left( R_1 s \frac{d}{ds} F_1(s)^2 + R_2 F_1(s)^2 \right) \bigg|_{s = M/N} = \sqrt{R_3} |M|^{-1/4} N^{1/4} C_1,
\]

\[
\left( R_1 s \frac{d}{ds} F_2(s)^2 + (R_1/2 + R_2) F_2(s) \right) \bigg|_{s = M/N} = \sqrt{R_3} |M|^{1/4} N^{3/4} C_1^{-1},
\]

and

\[
\left( R_1 t \frac{d}{dt} G_1(t)^2 + R_2 G_1(t)^2 \right) \bigg|_{t = M/N} = \sqrt{R_3} |M|^{2/3} N^{1/3} C_2,
\]

\[
\left( R_1 t \frac{d}{dt} G_2(t)^2 + (R_1/3 + R_2) G_2(t) \right) \bigg|_{t = M/N} = \sqrt{R_3} |M|^{1/3} N^{2/3} C_2^{-1},
\]

for some rational numbers $R_1, R_2, R_3$ depending on $d$, where

\[
C_1 = \frac{4}{\sqrt{12}} \frac{\pi}{\Omega_{-4}} = \frac{4}{\sqrt{12}} \frac{\Gamma(3/4)^2}{\Gamma(1/4)^2}, \quad C_2 = \frac{3}{\sqrt{2}} \frac{\pi}{\Omega_{-3}} = \frac{3}{\sqrt{2}} \frac{\Gamma(2/3)^3}{\Gamma(1/3)^3}.
\]
Combining these identities with the formulas in Theorem 2, we obtain special values for the functions
\[
\frac{d}{ds}F_1(s)^2 = \frac{d}{ds}F_2 \left( \frac{1}{12}, \frac{1}{4}, \frac{1}{12}, \frac{1}{2}, \frac{3}{4}, \frac{1}{s} \right) = \frac{5}{216}F_2 \left( \frac{13}{12}, \frac{5}{4}, \frac{17}{12}, \frac{3}{2}, \frac{7}{4}, \frac{1}{s} \right),
\]
\[
\frac{d}{ds}F_2(s)^2 = \frac{d}{ds}F_3 \left( \frac{7}{12}, \frac{3}{4}, \frac{11}{12}, \frac{3}{2}, \frac{5}{4}, \frac{1}{s} \right) = \frac{77}{360}F_2 \left( \frac{19}{12}, \frac{7}{4}, \frac{23}{12}, \frac{5}{2}, \frac{9}{4}, \frac{1}{s} \right),
\]
For instance, for \( d = -120 \), we have
\[
3F_2 \left( \frac{13}{12}, \frac{5}{4}, \frac{17}{12}, \frac{3}{2}, \frac{7}{4}, \frac{1}{153} \right) = \frac{3^6 \cdot 5^{9/4}}{2 \cdot 7^3 \cdot 19 \cdot \omega_2^{-4}} \left( \frac{4\sqrt{3} + 2\sqrt{10}}{\omega_{-120}^2} - \sqrt{3} \right),
\]
\[
3F_2 \left( \frac{19}{12}, \frac{7}{4}, \frac{23}{12}, \frac{5}{2}, \frac{9}{4}, \frac{1}{153} \right) = \frac{3^7 \cdot 5^{23/4} \cdot \omega_2^{-4}}{7^6 \cdot 11 \cdot 19} \left( 242(2\sqrt{3} - \sqrt{10})\omega_{-120}^2 - 7 \sqrt{3} \right).
\]
There are similar formulas for the functions
\[
3F_2 \left( \frac{13}{12}, \frac{4}{3}, \frac{19}{12}, \frac{11}{6}, \frac{5}{3}, \frac{1}{t} \right),
\]
\[
3F_2 \left( \frac{17}{12}, \frac{5}{3}, \frac{23}{12}, \frac{13}{6}, \frac{7}{3}, \frac{1}{t} \right),
\]
such as
\[
3F_2 \left( \frac{13}{12}, \frac{4}{3}, \frac{19}{12}, \frac{11}{6}, \frac{5}{3}, \frac{27}{196} \right) = \frac{2^4 \cdot 5 \cdot 7^{7/6}}{3^3 \cdot 13 \cdot \omega_2^{-3}} \left( \frac{4}{\sqrt{3}} - \sqrt{2}(3 + \sqrt{7})\omega_{-84}^2 \right),
\]
\[
3F_2 \left( \frac{17}{12}, \frac{5}{3}, \frac{23}{12}, \frac{13}{6}, \frac{7}{3}, \frac{27}{196} \right) = \frac{2^5 \cdot 7^{3/6} \cdot \omega_2^{-3}}{3^4 \cdot 5 \cdot 11 \cdot 13} \left( 4\sqrt{3} - 55\sqrt{2}(3 - \sqrt{7})\omega_{-84}^2 \right).
\]

Remark 2. Notice that the numbers \( A_1 \) in the first table are all of the form \( A^{1/8}(a + \sqrt{d})^{1/2} \) for some positive integer \( a \) and some rational number \( A \) whose denominator is 2 or 4. In other words, the special values \( _2F_1(1/24, 5/24; 3/4; M/N) \) possess a certain integrality property. This integrality property is a consequence of Schofer’s work [24] and our explicit realization of modular forms as Borcherds form. On the other hand, if we can somehow manage to prove this integrality property without using Borcherds forms, then to obtain the identities in Theorem 2 we can just evaluate the hypergeometric functions to a high precision and identify the integers. Note that the prime factors of the numerator of \( A \) are either 2 or prime factors of \( N \). This suggests that it may be possible to prove the integrality property using the moduli interpretation of the Shimura curve \( X_0^B(1) \).

Remark 3. Note that the proof of Theorem 1 is certainly valid for other Shimura curves \( X_0^B(N)/W \), \( W \) being a subgroup of the Atkin-Lehner groups, or even Shimura curves over totally real fields. However, other than the cases of arithmetic triangle groups, as classified in [28], there are only a very limited number of Shimura curves whose Schwarzian differential equations are known (see [12, 30]).

To obtain analogues of Theorem 2 for \( X_0^B(N)/W \), one will need a method to construct Borcherds forms systematically. This is recently addressed in [17], so there is no problem in evaluating modular forms on \( X_0^B(N)/W \) at CM-points. However, we remark that this only translates to analogues of the \( _2F_1 \)-evaluations. To obtain analogues of the \( _3F_2 \)-evaluations, we will need to determine the constant \( C \) such that the linear combination \( f_1 + C f_2 \) of two solutions \( f_1 \) and \( f_2 \) of the Schwarzian differential equation is a modular form. In general, this is a difficult problem. (For the case of \( X_0^B(1)/W_0 \), the constant \( C \) is determined by using Gauss’ formula \( _2F_1(a, b; c; 1) = \Gamma(c)\Gamma(c-a-b)/\Gamma(c-a)\Gamma(c-b) \).
If one wishes to further generalize Theorem 2 to Shimura curves over totally real fields, one will need the theory of Borcherds forms over totally real fields, developed recently by Bruinier and Yang [8, 9]. As far as we can see, it should in principle be possible to obtain explicit evaluations at least for the case of arithmetic triangle groups. We leave this problem for future investigation.

**Remark 4.** Notice that if a prime \( p \) divides \( M \), then the hypergeometric series appearing in Theorem 2 converges \( p \)-adically and one may wonder what the limit is. Our computation suggests the following \( p \)-adic evaluation.

For a prime \( p \), let \( \Gamma_p(x) \) be the \( p \)-adic Gamma function defined by

\[
\Gamma_p(n) = (-1)^n \prod_{0 < j < n, p \nmid j} j
\]

for positive integers \( n \) and extended continuously to \( \mathbb{Z}_p \), and for a fundamental discriminant \( d < 0 \), set

\[
\omega_{d,p} = \prod_{a=1}^{\lfloor |d|^{-1} \rfloor} \Gamma_p \left( \frac{a}{|d|} \right) \chi_d(a) \mu_d / 8 h_d.
\]

Consider the two hypergeometric functions in the first set of identities in Theorem 2. Other than the cases \( d = -52 \) and \( d = -132 \), the series converge \( 7 \)-adically. Then the numerical data suggest that

\[
\begin{align*}
2F1 \left( \frac{1}{24}, \frac{5}{24}; \frac{3}{4}; \frac{M}{N} \right) &= A_1 \frac{\omega_{d,7}}{\omega_{-4,7}}, \\
3F2 \left( \frac{1}{3}, \frac{1}{2}, \frac{3}{4}; \frac{5}{4}; \frac{M}{N} \right) &= A_2 \omega_{d,7}^2.
\end{align*}
\]

| \( d \) | \( A_1 \) | \( A_2 \) |
|---|---|---|
| \(-120\) | \( \frac{1}{2} \sqrt{-\frac{1}{125}} \sqrt{-3 + \sqrt{-10}} \) | \( 3 \) |
| \(-43\) | \( \sqrt{-10} \sqrt{\frac{1 + \sqrt{43}}{43}} \) | \( -100 \) |

We briefly explain the realization of modular forms on Shimura curves using solutions of Schwarzian differential equations. For details, see [36].

Assume that a Shimura curve $X$ has genus 0 with elliptic points and cusps $\tau_1, \ldots, \tau_r$ of order $e_1, \ldots, e_r$, respectively. (Here we set $e_j = \infty$ if $\tau_j$ is a cusp.) Let $t(\tau)$ be a Hauptmodul for $X$ and set $a_j = t(\tau_j)$. Then Theorem 4 of [36] shows that a basis for the space of modular forms of even weight $k \geq 4$ is

$$t' (\tau)^{k/2} t(\tau)^2 \prod_{i=1}^{r} (t(\tau) - a_i)^{-k \left[ 1 - 1/e_i \right]/2}, \quad j = 0, \ldots, d_k - 1,$$

where

$$d_k = 1 - k + \sum_{j=1}^{r} \left[ k/2 \left( 1 - 1/e_j \right) \right]$$

is the dimension of the space of modular forms of weight $k$ on $X$.

Now it is easy to check that $t'(\tau)$ is a meromorphic modular form of weight 2 on $X$. Thus, $t'(\tau)^{1/2}$ and $\tau t'(\tau)^{1/2}$, as functions of $t$, are solutions of a certain second-order linear differential equation with rational functions in $t$ as coefficients. (See [27] Theorem 5.1 or [33] Theorem 1. Here the coefficients of the differential equation are rational functions because $t$ is a Hauptmodul.) In fact, this differential equation is

$$\frac{d^2}{dt^2} F + Q(t) F = 0,$$

where

$$Q(t) = -\frac{1}{2} \left\{ t, \tau \right\}^2, \quad \left\{ t, \tau \right\} = \frac{t'''(\tau)}{t'(\tau)} - \frac{3}{2} \left( \frac{t''(\tau)}{t'(\tau)} \right)^2.$$

Because $\left\{ t, \tau \right\}$ is classically known as the Schwarzian derivative, we call the differential equation satisfied by $t'(\tau)^{1/2}$ and $t(\tau)$ the Schwarzian differential equation associated to the Shimura curve. If we let $\{ f_1, f_2 \}$ be a basis for the solution of (2), then we have $t'(\tau) = (c_1 f_1 + c_2 f_2)^2$ for some complex numbers $c_1$ and $c_2$. Substituting this into (1), we obtain realization of modular forms in terms of solutions of Schwarzian differential equations.
When a Shimura curve is of genus zero and has precisely three elliptic points or cusps, the Schwarzian differential equation is essentially a hypergeometric differential equation. In particular, for the curve \( X = X_0^6(1)/W_6 \), we can realize modular forms on \( X \) in terms of hypergeometric functions as follows.

We let \( B = \mathbb{Q} + \mathbb{Q}I + \mathbb{Q}J + \mathbb{Q}IJ \) with \( I^2 = -1, J^2 = 3 \), and \( IJ = -JI \), be the quaternion algebra of discriminant 6 over \( \mathbb{Q} \) and choose the embedding \( \iota : B \hookrightarrow M(2, \mathbb{R}) \) to be the one defined by

\[
\iota(I) = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}, \quad \iota(J) = \begin{pmatrix} \sqrt{3} & 0 \\ 0 & -\sqrt{3} \end{pmatrix}.
\]

Fix a maximal order \( \mathcal{O} = \mathbb{Z} + \mathbb{Z}I + \mathbb{Z}J + \mathbb{Z}(1 + I + J + IJ)/2 \) in \( B \) and choose representatives of CM-points of discriminants \(-3, -4, -24\) to be

\[
P_{-3} = \frac{-1 + i}{1 + \sqrt{3}}, \quad P_{-4} = i, \quad P_{-24} = \frac{(\sqrt{6} - \sqrt{2})i}{2}.
\]

They are the elliptic points of orders 6, 4, and 2, respectively. A fundamental domain is given by

Here the grey area represents a fundamental domain for \( X_0^6(1)/W_6 \). The four marked points on the boundary are \( P_{-4}, P_{-3}, P_{-24}, \) and \( (2 - \sqrt{3})i. \)

We have the following bases for the spaces of modular forms on \( X_0^6(1)/W_6 \).

**Proposition 5.** Let \( s \) be the Hauptmodul on \( X = X_0^6(1)/W_6 \) determined by \( s(P_{-4}) = 0 \), \( s(P_{-24}) = 1 \), and \( s(P_{-3}) = \infty \). Then for an even integer \( k \geq 4 \), a basis for the space \( S_k(X) \) of modular forms of weight \( k \) on \( X \) is

\[
s^{(3k/8)(1-s)}(1-s)^{(k/4)} s^j \left( \begin{array}{c} 2F1 \left( \frac{1}{24}, \frac{5}{24}; \frac{3}{4}; s \right) + \frac{1}{\sqrt{12}\omega_{-4}} s^{1/4} \right) 2F1 \left( \frac{7}{24}, \frac{11}{24}; \frac{5}{4}; s \right) \right)^k, j = 0, \ldots, d_k - 1,
\]

where \( d_k = \dim S_k(X) = 1 - k + \lfloor k/4 \rfloor + \lfloor 3k/8 \rfloor + \lfloor 5k/12 \rfloor \).

Also, let \( t = 1/s \). Then a basis for \( S_k(X) \) is

\[
t^{(5k/12)(1-t)}(1-t)^{(k/4)} t^j \left( \begin{array}{c} 2F1 \left( \frac{1}{24}, \frac{7}{24}; \frac{5}{6}; t \right) - \frac{e^{-2\pi i/8}}{\sqrt{3}\omega_{-3}} t^{1/6} \right) 2F1 \left( \frac{5}{24}, \frac{11}{24}; \frac{7}{6}; t \right) \right)^k, j = 0, \ldots, d_k - 1.
\]
Proof. The first part is the content of Lemmas 3 and 4 of [35]. For the second part, the proof of Lemma 14 of [36] shows that

\begin{equation}
(3) \quad t'(\tau) = \frac{6t^{5/6}(1-t)^{1/2}}{C(P_{-3} - \overline{P}_{-3})} \left( 2F_1 \left( \frac{1}{24}, \frac{7}{24}; \frac{5}{6}; t \right) - Ct^{1/6} 2F_1 \left( \frac{5}{24}, \frac{11}{24}; \frac{7}{6}; t \right) \right)^2,
\end{equation}

where

\begin{align*}
C &= \frac{P_{-24} - P_{-3}}{P_{-24} - \overline{P}_{-3}} \frac{\Gamma(5/6)\Gamma(17/24)\Gamma(23/24)}{\Gamma(7/6)\Gamma(13/24)\Gamma(19/24)}.
\end{align*}

Now

\begin{align*}
\frac{P_{-24} - P_{-3}}{P_{-24} - \overline{P}_{-3}} &= (1 - i) \left( 1 - \frac{1}{\sqrt{2}} \right) = e^{-2\pi i/8} (\sqrt{2} - 1).
\end{align*}

Also, by Euler’s reflection formula and Gauss’s multiplication formula, we have

\begin{align*}
\left( \frac{\Gamma(17/24)\Gamma(23/24)}{\Gamma(13/24)\Gamma(19/24)} \right)^2 &= \frac{\Gamma(17/24)\Gamma(23/24)\Gamma(5/24)\Gamma(11/24)}{\Gamma(13/24)\Gamma(19/24)\Gamma(1/24)\Gamma(7/24)} \\
&\times \frac{\sin(5\pi/24)\sin(11\pi/24)}{\sin(\pi/24)\sin(7\pi/24)} \\
&= 4^{-2/3} \frac{\Gamma(5/6)}{\Gamma(1/6)} (3 + 2\sqrt{2})
\end{align*}

and

\begin{align*}
\Gamma \left( \frac{1}{3} \right) \Gamma \left( \frac{5}{6} \right) &= (2\pi)^{1/2} 2^{-1/6} \Gamma \left( \frac{2}{3} \right).
\end{align*}

From these, we deduce that

\begin{align*}
\frac{\Gamma(5/6)\Gamma(17/24)\Gamma(23/24)}{\Gamma(7/6)\Gamma(13/24)\Gamma(19/24)} &= 6 \cdot 2^{-2/3}(\sqrt{2} + 1) \frac{\Gamma(5/6)^{3/2}}{\Gamma(1/6)^{3/2}} \\
&= 6 \cdot 2^{-2/3}(\sqrt{2} + 1) \frac{1}{(2\pi)^{3/2}} \frac{\Gamma \left( \frac{5}{6} \right)^3}{\Gamma(2/3)^3} \\
&= 6 \cdot 2^{-7/6}(\sqrt{2} + 1) \frac{\Gamma(2/3)^3}{\Gamma(1/3)^3} = \sqrt{2} + 1
\end{align*}

and hence

\begin{align*}
C &= \frac{e^{-2\pi i/8}}{\sqrt{2}\omega_{-3}}.
\end{align*}

Then from (1), we conclude that the second set of functions in the lemma forms a basis for $S_k(X)$.

For general Shimura curves, we can determine Schwarzian differential equations using Propositions 5 and 6 of [36] and explicit covers of Shimura curves. In [30], Tu determines Schwarzian differential equations for the cases when $X_{0}(1)/W$ and $X_{0}(N)/W$ both have genus zero.

We now give a proof of Theorem 1.

Proof of Theorem 1. Here we only prove the second half of the theorem; the proof of the first half is similar and is omitted.

Since $t(\tau)$ is a Hauptmodul that takes rational values at three distinct CM-points, it takes algebraic values at all CM-points. Thus, by [26, Theorem 7.1] and [37, Theorem 1.2]...
and (1.4) of Chapter 3, the value of $t'(\tau)$ at a CM-point of discriminant $d$ is an algebraic multiple of $\omega_d^\pm$. Then, from (3.4) of Chapter 3, the value of $t$ for all \( \tau \) lies in the fundamental domain depicted earlier. Then Equation (22) of [36] implies that 

\[
\frac{2F_1(5/24, 11/24; 7/6; t(\tau_d))}{2F_1(1/24, 7/24; 5/6; t(\tau_d))} \in \omega_{-3}^2 : \mathbb{Q}.
\]

Without loss of generality, we may assume that $\tau_d$ lies in the fundamental domain depicted earlier. Then Equation (22) of [36] implies that 

\[
2F_1 \left( \frac{1}{24}, \frac{7}{24} ; \frac{5}{6} ; t(\tau_d) \right) \in \frac{\omega_{d_0}}{\omega_{-3}} \cdot \mathbb{Q}.
\]

It follows that 

\[
2F_1 \left( \frac{1}{24}, \frac{7}{24} ; \frac{5}{6} ; t(\tau_d) \right) \in \frac{\omega_{d_0}}{\omega_{-3}} \cdot \mathbb{Q}
\]

and 

\[
3F_2 \left( \frac{1}{4}, \frac{1}{2}, \frac{3}{4}, \frac{5}{6} ; \frac{7}{6} ; t(\tau_d) \right) = 2F_1 \left( \frac{1}{24}, \frac{7}{24} ; \frac{5}{6} ; t(\tau_d) \right) 2F_1 \left( \frac{5}{24}, \frac{11}{24} ; \frac{7}{6} ; t(\tau_d) \right) \in \frac{\omega_{d_0}^2}{\omega_{-3}} \cdot \mathbb{Q}.
\]

This proves the theorem. \( \square \)

3. REALIZATION OF MODULAR FORMS AS BORCHERDS FORMS

We first give a quick introduction to Borcherds forms. For details, see [5, 6].

Let $L$ be an even lattice with a symmetric bilinear form $\langle \cdot, \cdot \rangle$ of signature $(b^+, b^-)$, $L^\vee = \{ \gamma \in L \otimes \mathbb{Q} : \langle \gamma, \eta \rangle \in \mathbb{Z} \text{ for all } \eta \in L \}$ its dual lattice, and $\{ e_{\eta} : \eta \in L^\vee / L \}$ the standard basis for the vector space $\mathbb{C}[L^\vee / L]$. Let

\[
\tilde{SL}(2, \mathbb{Z}) = \left\{ \left( \begin{array}{cc} a & b \\ c & d \end{array} \right), \pm \sqrt{cr+d} : \left( \begin{array}{cc} a & b \\ c & d \end{array} \right) \in SL(2, \mathbb{Z}) \right\}
\]

be the metaplectic double cover of $SL(2, \mathbb{Z})$, which is generated by

\[
S = \left( \begin{array}{cc} 0 & -1 \\ 1 & 0 \end{array} \right), \quad T = \left( \begin{array}{cc} 1 & 1 \\ 0 & 1 \end{array} \right).
\]

Associated to the lattice $L$, we have the Weil representation $\rho_L : \tilde{SL}(2, \mathbb{Z}) \to GL(\mathbb{C}[L^\vee / L])$ defined by

\[
\rho_L(T) e_\eta = e^{-2\pi i \langle \eta, \eta \rangle / 2} e_\eta,
\]

\[
\rho_L(S) e_\eta = e^{2\pi i (b^+ - b^-) / 8} \sum_{\gamma \in L^\vee / L} e^{2\pi i \langle \eta, \gamma \rangle} e_\eta.
\]

A holomorphic function $F : \mathbb{H}^+ \to \mathbb{C}[L^\vee / L]$ is said to be a weakly holomorphic vector-valued modular form of weight $k$ in $\frac{k}{2} \mathbb{Z}$ and type $\rho_L$ if it satisfies

\[
F \left( \frac{a\tau + b}{c\tau + d} \right) = (c\tau + d)^k \rho_L \left( \begin{array}{cc} a & b \\ c & d \end{array} \right), \sqrt{cr+d} \right) F(\tau)
\]

for all $\tau \in \mathbb{H}^+$ and all \( \left( \begin{array}{cc} a & b \\ c & d \end{array} \right) \in SL(2, \mathbb{Z}) \) and the principal part of its Fourier expansion

\[
F(\tau) = \sum_{\eta} (\sum_{m \in \mathbb{Q}} c_\eta(m) q^m) e_\eta, \quad q = e^{2\pi i \tau},
\]

has finitely many terms, i.e., the number of pairs $(\eta, m)$ with $m < 0$ and $c_\eta(m) \neq 0$ is finite.
For $k = \mathbb{Q}, \mathbb{R}$, or $\mathbb{C}$, let $V(k) = L \otimes k$ and extend the definition of $\langle \cdot, \cdot \rangle$ to $V(k)$ by linearity. Define the orthogonal groups
\[ O_V(\mathbb{R}) = \{ \sigma \in \text{GL}(V(\mathbb{R})) : \langle \sigma x, \sigma y \rangle = \langle x, y \rangle \text{ for all } x, y \in V(\mathbb{R}) \} \]
and
\[ O_V^+(\mathbb{R}) = \{ \sigma \in O_V(\mathbb{R}) : \text{spin } \sigma = \text{sgn } \det \sigma \}, \]
where if $\sigma$ is equal to the product of $n$ reflections with respect to the vectors $v_1, \ldots, v_n$, then its spinor norm is defined by $\text{spin } \sigma = (-1)^n \prod_{i=1}^n \text{sgn } \langle v_i, v_i \rangle$. Let also
\[ O_L = \{ \sigma \in O_V(\mathbb{R}) : \sigma(L) = L \}, \quad O_L^+ = O_L \cap O_V^+(\mathbb{R}). \]
(Note that the definition of spinor norms is different from that of [5] since the bilinear form in our setting differs from that of [5] by a factor of $-1$.)

From now on, we assume that the signature of $L$ is $(b, 2)$. Let $\text{Gr}(V(\mathbb{R}))$ be the Grassmannian of oriented negative 2-planes in $V(\mathbb{R})$. For an element $A$ in $\text{Gr}(V(\mathbb{R}))$, we can find an oriented basis $\{x, y\}$ for $A$ with $\langle x, x \rangle = \langle y, y \rangle = -1$ and $\langle x, y \rangle = 0$. Let $z = x + iy \in V(\mathbb{C})$. Then we have $\langle z, z \rangle = 0$ and $\langle z, \overline{z} \rangle < 0$. In fact, it is easy to show that $\text{Gr}(V(\mathbb{R}))$ can be identified with the set
\[ K = \{ z \in V(\mathbb{C}) : \langle z, z \rangle = 0, \langle z, \overline{z} \rangle < 0 \}/\mathbb{C}^x. \]
The set $K$ has two connected components, which amount to the two choices of continuously varying orientation of negative 2-planes in $V(\mathbb{R})$. Pick one of them to be $K^+$. Then the orthogonal group $O_V^+(\mathbb{R})$ acts transitively on $K^+$. Let
\[ \tilde{K}^+ = \{ z \in V(\mathbb{C}) : \langle z, z \rangle = 0, \langle z, \overline{z} \rangle < 0, [z] \in K^+ \}. \]
Then for a subgroup $\Gamma$ of $O_V^+(\mathbb{R})$, a meromorphic function $\Psi : \tilde{K}^+ \to \mathbb{P}^1(\mathbb{C})$ is called a modular form of weight $k$ with character $\chi$ on $\Gamma$ if $\Psi$ satisfies
\begin{enumerate}
  \item $\Psi(cz) = c^{-k} \Psi(z)$ for all $c \in \mathbb{C}^x$ and $z \in \tilde{K}^+$, and
  \item $\Psi(gz) = \chi(g) \Psi(z)$ for all $g \in \Gamma$ and $z \in \tilde{K}^+$.
\end{enumerate}

**Theorem A ([5] Theorem 13.3).** Let $L$ be an even lattice of signature $(b, 2)$ and $F(\tau)$ be a weakly holomorphic vector-valued modular form of weight $1 - b/2$ and type $\mu_L$ with Fourier expansion $F(\tau) = \sum_{\eta \in \mathbb{C}^L} F_\eta(\tau)e_\eta = \sum_{\eta \in \mathbb{C}^L} \sum_{m \in \mathbb{C}} c_\eta(m)q^m e_\eta$. Suppose that $c_\eta(m) \in \mathbb{Z}$ whenever $m \leq 0$. Then there corresponds a meromorphic function $\Psi_F(z)$, $z \in \tilde{K}^+$, with the following properties.

1. $\Psi_F(z)$ is a meromorphic modular form of weight $c_0(0)/2$ on the group $O_{L,F}^+ = \{ \sigma \in O_L^+ : F_\sigma = F_\eta \text{ for all } \eta \in L^/L \}$ with respect to some unitary character $\chi$ of $O_{L,F}^+$.
2. The only zeros or poles of $\Psi_F(z)$ lie on the rational quadratic divisor $\lambda^+ = \{ z \in \tilde{K}^+ : \langle z, \lambda \rangle = 0 \}$ for $\lambda \in L$, $\langle \lambda, \lambda \rangle > 0$ and are of order $\sum_{0 < r \in \mathbb{Q}, r \lambda \in L^/L} c_{r,\lambda}(-r^2 \langle \lambda, \lambda \rangle / 2)$. We call the function $\Psi_F(z)$ the **Borcherds form** associated to $F(\tau)$. We now explain the idea of realizing modular forms on Shimura curves in terms of Borcherds forms. Even though this idea has been used in [13], it seems to us that some key properties were not explained very concretely in [13]. For instance, it was not explained in [13] why the characters associated to the Borcherds forms constructed therein are trivial. Therefore, it is worthwhile to explain this approach in some details.
Let $\mathcal{O}$ be an Eichler order of level $N$ in an indefinite quaternion algebra $B$ of discriminant $D$ over $\mathbb{Q}$, $(N,D) = 1$, $\mathcal{O}_1$ be the group of norm-one elements in $\mathcal{O}$, and
\[ L = \{ \alpha \in \mathcal{O} : \text{tr}(\alpha) = 0 \} \]
be the set of elements of trace zero in $\mathcal{O}$, where $\text{tr}(\alpha)$ and $n(\alpha)$ denote the trace and the norm of $\alpha$, respectively. By setting $(\alpha, \beta) = \text{tr}(\alpha \beta')$, $L$ becomes a lattice of signature $(1,2)$, where $\beta'$ denote the quaternionic conjugate of $\beta$ in $B$. We now determine $O_L$ and $O_L^+$. 

By the Cartan-Dieudonné theorem, every isometry $\sigma$ in $O_V(\mathbb{R})$ is equal to the product of at most three reflections. Now it is clear that for an element of nonzero norm $\alpha$ in $V(\mathbb{R})$, the function $\tau_\alpha : \gamma \to -\alpha \gamma \alpha^{-1}$ sends $\alpha$ to $-\alpha$ and leaves any element of $V(\mathbb{R})$ orthogonal to $\alpha$ fixed. (Here we regard $V(\mathbb{R})$ as the set of trace-zero elements in the quaternion algebra $B \otimes \mathbb{R}$ and define multiplication and inverse accordingly.) In other words, $\tau_\alpha$ is the reflection with respect to $\alpha$. Thus, $\sigma$ has determinant $1$, i.e., $\sigma$ is the product of an even number of reflections, if and only if $\sigma$ is the isometry $\sigma_\beta : \gamma \to \beta \gamma \beta^{-1}$ induced by the conjugation by an element $\beta$ of nonzero norm in $B \otimes \mathbb{R}$ and $\sigma$ has determinant $-1$ if and only if $\sigma = -\sigma_\beta$ for some $\beta$. From this, we deduce that
\[ O_V(\mathbb{R}) = \{ \sigma_\beta : \beta \in (B \otimes \mathbb{R})/\mathbb{R}^\times, \ n(\beta) \neq 0 \} \times \{ \pm 1 \} \]
and
\[ O_V^+(\mathbb{R}) = \{ \sigma_\beta : \beta \in (B \otimes \mathbb{R})/\mathbb{R}^\times, \ n(\beta) > 0 \} \times \{ \pm 1 \} \]
In addition, by the Noether-Skolem theorem, if $\sigma_\beta, \beta \in B \otimes \mathbb{R}$, satisfies $\sigma_\beta(V(\mathbb{Q})) = V(\mathbb{Q})$, then $\beta$ can be chosen from $B$. It follows that
\[ O_L = \{ \sigma_\beta : \beta \in N_B(O)/\mathbb{Q}^\times \} \times \{ \pm 1 \} \]
and
\[ O_L^+ = \{ \sigma_\beta : \beta \in N_B^+(O)/\mathbb{Q}^\times \} \times \{ \pm 1 \} \]
where $N_B(O)$ denotes the normalizer of $O$ in $B$ and $N_B^+(O)$ is the subgroup of elements of positive norm in $N_B(O)$.

Now assume that the quaternion algebra $B$ is represented by $B = \left( \frac{a,b}{\mathbb{Q}} \right)$ with $a,b > 0$. That is, $B = \mathbb{Q} + \mathbb{Q}I + \mathbb{Q}J + \mathbb{Q}IJ$ with $I^2 = a$, $J^2 = b$, and $IJ = -JI$. Fix an embedding $\iota : B \to M(2,\mathbb{R})$ by
\[ \iota : I \to \left( \frac{0}{\sqrt{a}}, \frac{\sqrt{a}}{0} \right), \ J \to \left( \frac{\sqrt{b}}{0}, \frac{0}{-\sqrt{b}} \right). \]
We can show that each class in $K = \{ z \in V(\mathbb{C}) : \langle z,z \rangle = 0, \langle z,\overline{z} \rangle < 0 \}/\mathbb{C}^\times$ contains a unique representative of the form
\[ z(\tau) = \frac{1 - \tau^2}{2\sqrt{a}} I + \frac{\tau}{\sqrt{b}} J + \frac{1 + \tau^2}{2\sqrt{ab}} IJ \]
for some $\tau \in \mathbb{H}^\times$, the union of the upper and lower half-planes, and the mapping $\tau \to z(\tau)$ mod $\mathbb{C}^\times$ is a bijection between $\mathbb{H}^\times$ and $K$. Let $K^+$ be the image of $\mathbb{H}^+$ under this mapping. Now the group $N_B^+(O)/\mathbb{Q}^\times$ acts on $\mathbb{H}^+$ by linear fractional transformation through the embedding $\iota$ and also on $K^+$ by conjugation. By a straightforward computation, we can verify that the actions are compatible. To be more concrete, for $\alpha \in N_B^+(O)$, if we write $\iota(\alpha) = (c_1, c_2)$, then for all $\tau \in \mathbb{H}^+$, we have
\[ \alpha z(\tau) \alpha^{-1} = \frac{(c_3 \tau + c_4)^2}{n(\alpha)} z \left( \frac{c_1 \tau + c_2}{c_3 \tau + c_4} \right). \]
Thus, if \( \Psi(z) \) is a meromorphic modular form of weight \( k \) on \( \mathcal{O}_L^+ \) with character \( \chi \), then the function \( \psi(\tau) \) defined by \( \psi(\tau) = \Psi(z(\tau)) \) is a meromorphic modular form of weight \( 2k \) with character on the Shimura curve \( \mathcal{N}_B^{+}(\mathcal{O}) \backslash \mathbb{H}^{+} \). Since the group \( \mathcal{N}_B^{+}(\mathcal{O})/(\mathbb{Q} \times \mathcal{O}_0) \) contains the Atkin-Lehner group, we find that \( \psi(\tau) \) is a modular form on \( X_0^D(N)/W_{D,N} \), the quotient of the Shimura curve \( X_0^D(N) \) by the group \( W_{D,N} \) of all Atkin-Lehner involutions. In particular, we have the following lemma.

**Lemma 6.** Let \( F(\tau) = \sum_{\eta} \left( \sum_{m} c_{\eta}(m)q^{m} \right) e_\eta \) be a weakly holomorphic vector-valued modular form of weight \( 1/2 \) and type \( \rho_\eta \) such that \( \mathcal{O}_{L,F} = \mathcal{O}_L^{+} \) and \( c_{\eta}(m) \in \mathbb{Z} \) whenever \( m \leq 0 \). Then the function \( \psi_F(\tau) \) defined by \( \psi_F(\tau) = \Psi_F(z(\tau)) \) is a meromorphic modular form of weight \( c_0(0) \) with certain unitary character \( \chi \) on the Shimura curve \( X_0^D(N)/W_{D,N} \).

We now determine the divisor of \( \psi_F(\tau) \). According to Borcherds’ theorem, the divisor of \( \Psi_F(z) \) is supported on \( \lambda^d \) for \( \lambda \in L \) with positive norm such that \( c_{\eta}(\lambda^2|-n(\lambda)) \neq 0 \) for some positive rational number \( r \). Now suppose that \( \lambda \) is such an element of \( L \). The condition \( \langle \lambda, z \rangle = 0 \) implies that \( \lambda z \lambda^{-1} = -z = z \mod \mathbb{C}^\times \). That is, \( \lambda^2 \mathbb{C}^\times \) consists of the point \( z_\lambda \) in \( \mathbb{H}^+ \) fixed by the action of \( \lambda \) and the corresponding point \( \tau_\lambda \) in \( \mathbb{H}^+ \) is a CM point. Let \( E = \mathbb{Q}(\sqrt{-n(\lambda)}) \) and \( \phi : E \rightarrow B \) be the embedding determined by \( \phi(\sqrt{-n(\lambda)}) = \lambda \). Then the discriminant of this CM-point is the discriminant of the quadratic order \( R \) in \( E \) such that \( \phi(E) \cap \mathcal{O} = \phi(R) \). Note, however, that if the CM-point \( \tau_\lambda \) happens to be an elliptic point of order \( e \), then the projection \( \mathbb{H}^+ \simeq \mathbb{H}^+ \rightarrow X_0^D(N)/W_{D,N} \) is locally \( e \)-to-1 at \( \tau_\lambda \). Thus, the order of the modular form \( \psi_F(\tau) \) at \( \tau_\lambda \) is \( 1/e \) of that of \( \Psi_F(z) \) at \( z_\lambda \).

In practice, to have a simpler description of the divisor of \( \psi_F(\tau) \), we often assume that the weakly holomorphic vector-valued modular form \( F \) has the property that the only \( \eta \in L^n/L \) such that \( c_{\eta}(m) \neq 0 \) for some \( m < 0 \) is \( 0 \). In such a case, if we assume that \( \lambda \) is primitive, that is, \( \lambda/n \notin \mathcal{O} \) for any positive integer \( n \geq 2 \), then the discriminant of the CM-point \( \tau_\lambda \) is either \( -n(\lambda) \) or \( -4n(\lambda) \), depending on whether \( (1 + \lambda)/2 \) is in \( \mathcal{O} \) or not. In summary, the divisor of \( \psi_F(\tau) \) can be described as follows.

**Lemma 7.** Let \( F(\tau), \Psi_F(z), \) and \( \psi_F(\tau) \) be as in the previous lemma. Assume in addition that the only \( \eta \in L^\times/L \) such that \( c_{\eta}(m) \neq 0 \) for some \( m < 0 \) is \( 0 \). Then we have
\[
\text{div } \psi_F = \sum_{m < 0} c_\eta(m) \sum_{r \in \mathbb{Z}^+} \frac{1}{e_{4m/r^2}} \sum_{\tau \in \text{CM}(4m/r^2)} \tau,
\]
where for a negative discriminant \( d \), \( \text{CM}(d) \) denotes the set of CM-points of discriminant \( d \) (which might be empty) and \( e_d \) is the cardinality of the stabilizer of \( \tau \in \text{CM}(d) \) in \( \mathcal{N}_B^{+}(\mathcal{O})/\mathbb{Q}^\times \).

We next determine when the character of a Borcherds form \( \psi_F(\tau) \) is trivial, under the assumption that the genus of \( \mathcal{N}_B^{+}(\mathcal{O}) \backslash \mathbb{H}^{+} \) is zero.

**Lemma 8.** Assume that the genus of \( X = \mathcal{N}_B^{+}(\mathcal{O}) \backslash \mathbb{H}^{+} \) is zero. Let \( \tau_1, \ldots, \tau_r \) be the elliptic points of \( X \) and assume that their orders are \( b_1, \ldots, b_r \), respectively. Assume further that, as CM-points, the discriminants of \( \tau_1, \ldots, \tau_r \) are \( d_1, \ldots, d_r \), respectively. Let \( F(\tau) = \sum_{\eta} \left( \sum_{m} c_{\eta}(m)q^{m} \right) e_\eta \) be a weakly holomorphic vector-valued modular form of weight \( 1/2 \) and type \( \rho_\eta \) such that \( \mathcal{O}_{L,F} = \mathcal{O}_L^{+} \) and \( c_{\eta}(m) \in \mathbb{Z} \) whenever \( m \leq 0 \). Assume that \( c_0(0) \) is even. Then the character associated to the modular form \( \psi_F(\tau) \) is trivial if and only if for all \( j \) such that \( b_j \neq 3 \), the order of \( \Psi_F(z) \) at \( z(\tau_j) \) has the same parity as \( c_0(0)/2 \).
Proof. Let $\gamma_1, \ldots, \gamma_r$ be generators of the stabilizer subgroups of $\tau_1, \ldots, \tau_r$ in the group $\Gamma = N_B^+(O)/Q^\times$. Since $X$ is assumed to be of genus zero, the group $\Gamma$ is generated by $\gamma_1, \ldots, \gamma_r$ with a single relation
\begin{equation}
\gamma_1 \cdots \gamma_r = 1,
\end{equation}
after a suitable reindexing. (See [18] Chapter 4.)

Recall that the order of an elliptic point can only be 2, 3, 4, or 6. Also, an elliptic point of order 3 or 6 is necessarily a CM-point of discriminant $-3$ and a CM-point of discriminant $-3$ is an elliptic point of order 3 or 6 depending on whether $3 \nmid DN$ or $3 | DN$. In particular, an elliptic point of order 3 and an elliptic point of order 6 cannot exist at the same time. Moreover, on $X_0^D(N)/W_{D,N}$, there can be at most one CM-point of discriminant $-3$. Likewise, an elliptic point of order 4 is necessarily a CM-point of discriminant $-4$ and on $X_0^D(N)/W_{D,N}$ there can be at most one such point. Therefore, there are at most two elliptic points whose orders are different from 2.

Consider the case where there is one or zero elliptic point whose order is different from 2 first. By (6), to show that the character $\chi$ associated to the modular form $\psi_F(\tau)$ is trivial, it suffices to prove that $\chi(\gamma_j) = 1$ for $j$ with $b_j = 2$.

Observe that for $j$ with $b_j = 2$, $\gamma_j$ is an element of order 2 in $\Gamma$ and hence of trace zero and positive norm. Now by the compatibility relation (5), if we write $\kappa(\gamma_j) = (c_1, c_2)$ and set $k = c_0(0)$, then
\begin{equation}
\psi_F\left( \frac{c_1 \tau + c_2}{c_3 \tau + c_4} \right) = \Psi_F\left( \frac{n(\gamma_j)}{(c_3 \tau + c_4)^2} \gamma_j z(\tau) \gamma_j^{-1} \right) = \frac{(c_3 \tau + c_4)^k}{n(\gamma_j)^{k/2}} \psi_F\left( \gamma_j z(\tau) \gamma_j^{-1} \right).
\end{equation}

Let $\sigma_j$ be the element of $O_L^+$ that corresponds to the reflection with respect to $\gamma_j$. We have $\sigma_j : z \mapsto -\gamma_j z \gamma_j^{-1}$. Being a reflection, $\sigma_j$ acts on $\psi_F(z)$ as +1 or −1, depending on whether $\psi_F(z)$ has an even order or an odd order at the fixed point $z(\tau_j)$ of $\sigma_j$. Thus, assuming the order of $\Psi_F(z)$ at $z(\tau_j)$ has the same parity as $k/2 = c_0(0)/2$, we have
\begin{align*}
\psi_F\left( \frac{c_1 \tau + c_2}{c_3 \tau + c_4} \right) &= \frac{(c_3 \tau + c_4)^k}{n(\gamma_j)^{k/2}} \psi_F(-\sigma_j z(\tau)) \\
&= (-1)^{k/2} \frac{(c_3 \tau + c_4)^k}{n(\gamma_j)^{k/2}} \psi_F(\sigma_j z(\tau)) \\
&= \frac{(c_3 \tau + c_4)^k}{n(\gamma_j)^{k/2}} \psi_F(z(\tau)) = \frac{(c_3 \tau + c_4)^k}{n(\gamma_j)^{k/2}} \psi_F(\tau).
\end{align*}

Therefore, if the order of $\Psi_F(z)$ at $z(\tau_j)$ has the same parity as $k/2 = c_0(0)/2$ for all $j$ with $b_j = 2$, then $\psi_F(\tau)$ is a modular form with trivial character on $X$.

Now consider the remaining case where there are two elliptic points of order different from 2. By the remark made earlier, the orders of these two elliptic points can only be 3 and 4 or 4 and 6. By the same argument in the previous paragraph, we find that, under the assumption of the lemma, for all $j$ with $b_j$ even, we have $\chi(\gamma_j^{b_j/2}) = 1$. It follows that if $b_j = 4$, then $\chi(\gamma_j)^2 = 1$ and if $b_j = 3$ or $b_j = 6$, then $\chi(\gamma_j)^3 = 1$. Since $\chi(\gamma_1) \cdots \chi(\gamma_r) = 1$, we conclude that $\chi(\gamma_j) = 1$ for all $j$. This proves the lemma.

For the case of $X_0^6(1)/W_6$ under consideration, there are three elliptic points of order 2, 4, and 6, respectively. They are CM-points of discriminants $-24$, $-4$, and $-3$, respectively. The proof of the above lemma gives us the following criterion for a Borcherds form $\psi_F(\tau)$ to be a modular form with trivial character on $X_0^6(1)/W_6$. 

\begin{proof}
...
Corollary 9. Let \( \mathcal{O} \) be a maximal order in the quaternion algebra of discriminant 6 over \( \mathbb{Q} \) and \( L \) be the lattice formed by the elements of trace zero in \( \mathcal{O} \). Suppose that \( F(\tau) = \sum_{\eta} (\sum_{m} c_\eta(m)q^m)e_\eta \) is a weakly holomorphic vector-valued modular form of weight 1/2 and type \( \rho_L \) such that \( c_\eta(m) \in \mathbb{Z} \) whenever \( m \leq 0 \) and \( O^+_L, F = O^+_L \). Assume in addition that

1. the only \( \eta \in L^\vee / L \) such that \( c_\eta(m) \neq 0 \) for some \( m < 0 \) is 0, and
2. \( c_0(0) \) is even and
\[
\sum_{m=-r^2} c_0(m) \equiv \sum_{m=-3r^2} c_0(m) \equiv c_0(0)/2 \text{ mod } 2.
\]

Then the Borcherds form \( \psi_F(\tau) = \Psi_F(z(\tau)) \) is a modular form of weight \( c_0(0) \) and trivial character on the Shimura curve \( X^6_0(1)/W_6 \).

Finally, we introduce Errthum’s method for constructing \( F(\tau) \) satisfying the conditions in the lemma above \([13]\). Here we consider general Eichler orders in an indefinite quaternion algebra over \( \mathbb{Q} \).

The first lemma shows that we can construct \( F(\tau) \) out of a scalar-valued modular form with suitable properties. To state the required properties, we let \( \chi_\theta \) denote the character associated to the Jacobi theta function \( \theta(\tau) = \sum_{n \in \mathbb{Z}} q^{n^2} \). That is, \( \chi_\theta \) is the character satisfying
\[
\theta(\gamma \tau) = \chi_\theta(\gamma)(ct + d)^{1/2}\theta(\tau)
\]
for all \( \gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \Gamma_0(4) \) and all \( \tau \in \mathbb{H}^+ \). For a scalar-valued modular form \( f(\tau) \) of weight \( \gamma \in \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \Gamma_0(M) \), we let
\[
f_\gamma(\tau) = (ct + d)^{-\gamma} f(\gamma \tau).
\]
We observe that the level \( M \) of the lattice \( L \) is always a multiple of 4 for any \( D \) and \( N \).

Lemma 10 \([13]\) Theorem 4.2.9). Let \( M \) be the level of the lattice \( L \). Suppose that \( f(\tau) \) is a weakly holomorphic scalar-valued modular form of weight 1/2 such that
\[
f_\gamma(\tau) = \chi_\theta(\gamma)(ct + d)^{1/2} f(\tau)
\]
for all \( \gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \Gamma_0(M) \). Then the function \( F_f(\tau) \) defined by
\[
F_f(\tau) = \sum_{\gamma \in \tilde{\Gamma}_0(M) \backslash \tilde{\mathbb{SL}(2,\mathbb{Z})}} f_\gamma(\tau) \rho_L(\gamma^{-1}) e_\gamma
\]
is a weakly holomorphic vector-valued modular form of weight 1/2 and type \( \rho_L \).

Lemma 11 \([13]\) Proposition 5.4). Suppose that the weakly holomorphic modular form \( f(\tau) \) in the above lemma has a pole only at the infinity cusp. Then the Fourier expansion \( F_f(\tau) = \sum_{\eta} (\sum_{m} c_\eta(m)q^m)e_\eta \) satisfies \( c_\eta(m) = 0 \) whenever \( \eta \neq 0 \) and \( m < 0 \).

Lemma 12 \([13]\) Theorem 5.8]). Let \( f(\tau) \) and \( F_f(\tau) \) be given as in the previous lemmas. Then for any \( \eta, \eta' \in L^\vee \) with \( \langle \eta, \eta \rangle = \langle \eta', \eta' \rangle \), the \( e_\eta \)-component and the \( e_{\eta'} \)-component of \( F_f(\tau) \) are equal. Consequently, we have \( O^+_L, F = O^+_L \).

It remains to construct scalar-valued modular forms \( f(\tau) \) satisfying the condition in Lemma 10.

Lemma 13 \([6]\) Theorem 6.2]). Let \( M \) be the level of the lattice \( L \). Suppose that \( r_d, d \mid M \), are integers satisfying the conditions
1. \( \sum_{d \mid M} r_d = 1 \),
(2) \( |L'|/L |\prod_{d|M} d^{r_d} \) is a square in \( \mathbb{Q}^\times \),
(3) \( \sum_{d|M} dr_d \equiv 0 \mod 24 \), and
(4) \( \sum_{d|M} (M/d)r_d \equiv 0 \mod 24 \).

Then \( \prod_{d|M} \eta(d\tau)^{r_d} \) is a weakly holomorphic modular form satisfying the condition for \( f(\tau) \) in Lemma \[10\].

We now consider the case of \( X_0^6(1)/W_6 \).

**Proposition 14.** Consider the case \( X_0^6(1)/W_6 \). Let
\[
f(\tau) = 2 \eta(2\tau)\eta(3\tau)\eta(4\tau)^4\eta(6\tau)^4 \eta(12\tau)^{10} + 2 \eta(\tau)\eta(2\tau)^3\eta(6\tau)^2 \eta(3\tau)\eta(4\tau)\eta(12\tau)^3.
\]
and
\[
g(\tau) = 2 \eta(\tau)\eta(2\tau)^3\eta(6\tau)^2 \eta(3\tau)\eta(4\tau)\eta(12\tau)^3.
\]

Let \( F_f(\tau) \) and \( F_g(\tau) \) be defined as in \[7\]. Then \( \psi_{F_f}(\tau) \) and \( \psi_{F_g}(\tau) \) span the one-dimensional spaces of holomorphic modular form on \( X_0^6(1)/W_6 \) of weight 8 and 12, respectively.

**Proof.** The two eta-products were found in \[13\] Page 848]. Here we give a quick explanation.

In the case of \( X_0^6(1)/W_6 \), the lattice \( L \) has level 12 and \( |L'|/L| = 72 \). The two eta-products clearly satisfy the four conditions in Lemma \[13\]. Now the congruence subgroup \( \Gamma_0(12) \) has 6 cusps, represented by \( 1/c, c|12 \). The orders of the eta functions \( \eta(d\tau) \) at these cusps, multiplied by 24, are given by the table.

| \( d\tau \) | 1/1 | 1/2 | 1/4 | 1/3 | 1/6 | 1/12 |
|---|---|---|---|---|---|---|
| \( \eta(\tau) \) | 12 | 3 | 3 | 4 | 1 | 1 |
| \( \eta(2\tau) \) | 6 | 6 | 6 | 2 | 2 | 2 |
| \( \eta(4\tau) \) | 3 | 3 | 12 | 1 | 1 | 4 |
| \( \eta(3\tau) \) | 4 | 1 | 1 | 12 | 3 | 3 |
| \( \eta(6\tau) \) | 2 | 2 | 2 | 6 | 6 | 6 |
| \( \eta(12\tau) \) | 1 | 1 | 4 | 3 | 3 | 12 |

From the table, we see that the two eta-products have only a pole at the cusp \( 1/12 \sim \infty \). Thus, by Lemma \[11\], the divisors of \( \psi_{F_f}(\tau) \) and \( \psi_{F_g}(\tau) \) are determined by the \( e_0 \)-components of the Fourier expansions of \( F_f(\tau) \) and \( F_g(\tau) \). Since \( f(\tau) = 2q^{-3} - 6 - 18q + ... \) and \( g(\tau) = 2q^{-1} - 2 - 8q + 8q^2 + ... \), the \( e_0 \)-components of \( F_f(\tau) \) and \( F_g(\tau) \) are
\[
2q^{-3} + c_0 + ... , \quad 2q^{-1} + d_0 + ...
\]
for some \( c_0 \) and \( d_0 \), respectively. The numbers \( c_0 \) and \( d_0 \) are complicated to compute directly from the definition of \( F_f \) and \( F_g \). Here we observe that, by Lemma \[7\],
\[
\text{div } \psi_{F_f}(\tau) = \frac{1}{3} P_{-3}, \quad \text{div } \psi_{F_g}(\tau) = \frac{1}{2} P_{-4},
\]
where \( P_{-3} \) and \( P_{-4} \) denote the unique CM-points of discriminants \(-3\) and \(-4\), respectively. (Note that there does not exist a CM-point of discriminant \(-12\) on \( X_0^6(1)/W_6 \).) Therefore, the weight of \( \psi_{F_f}(\tau) \) must be 8 and the weight of \( \psi_{F_g}(\tau) \) must be 12. In other words, we have \( c_0 = 8 \) and \( d_0 = 12 \). Then, by Corollary \[7\], \( \psi_{F_f}(\tau) \) and \( \psi_{F_g}(\tau) \) must be modular forms on \( X_0^6(1)/W_6 \) with trivial characters. This proves the proposition. \( \square \)
Combining Proposition 5 and Proposition 14, we find that

\[ \psi_{F_1}(\tau) = C_1 \left( 2F_1 \left( \frac{1}{24}, \frac{5}{24}, \frac{3}{4}; s \right) + \frac{1}{\sqrt{12\omega^2}} s^{1/4} 2F_1 \left( \frac{7}{24}, \frac{11}{24}, \frac{5}{4}; s \right) \right)^8 \]

and

\[ \psi_{F_2}(\tau) = C_2 \left( 2F_1 \left( \frac{1}{24}, \frac{7}{24}, \frac{5}{6}; t \right) - \frac{e^{-2\pi i/8}}{\sqrt{2\omega^2}} t^{1/6} 2F_1 \left( \frac{5}{24}, \frac{11}{24}, \frac{7}{6}; t \right) \right)^{12} \]

for some complex numbers \( C_1 \) and \( C_2 \). To determine the absolute values of these two numbers, we shall use Schofer’s formula for values of Borcherds forms at CM-points.

4. Schofer’s Formula for Values of Borcherds Forms at CM-points

Let \( \mathcal{O} \) be an Eichler order of level \( N \) in an indefinite quaternion algebra of discriminant \( D \) over \( \mathbb{Q} \). Throughout this section, we assume that the level \( N \) is squarefree and the symbol \( d \) always denote a negative fundamental discriminant. Let \( L = \{ \alpha \in \mathcal{O} : tr(\alpha) = 0 \} \) be the lattice of signature \((1,2)\) formed by the elements of trace 0 in \( \mathcal{O} \). We retain all the notations \((\cdot, \cdot), V(\mathbb{Q}), V(\mathbb{R}), V(\mathbb{C}), K, K^+, \mathcal{O}_L, \mathcal{O}_{L,F}, \text{etc.} \) used in the previous section. Here let us summarize Schofer’s formula [24] for average values of Borcherds forms at CM-points first. The explanation of the terms involved will be given later.

**Theorem B ([24] Corollaries 1.2 and 3.5]).** Let \( F(\tau) = \sum_{\eta}(\sum_m c_\eta(m)q^m)e_\eta \) be a weakly holomorphic vector-valued modular form of weight \( 1/2 \) and type \( \rho_L \) such that \( \mathcal{O}_{L,F}^+ = \mathcal{O}_L^+ \) and \( c_\eta(m) \in \mathbb{Z} \) whenever \( m \leq 0 \). Let \( \Psi_\mathcal{F}(z) \) be the Borcherds form associated \( F(\tau) \) and \( \psi_\mathcal{F}(\tau) = \Psi_\mathcal{F}(\tau) \) be the modular form of weight \( c_\eta(0) \) on \( \mathcal{X}_0^D(N) / W_{D,N} \) as described in Lemma 6, where \( z(\tau) \) is given by 4. Let \( d < 0 \) be a fundamental discriminant such that the set \( \text{CM}(d) \) of CM-points of discriminant \( d \) is not empty and that the support of \( \text{div} \psi(\tau) \) does not intersect \( \text{CM}(d) \). Then we have

\[
\sum_{\tau \in \text{CM}(d)} \log \left| \psi_\mathcal{F}(\tau)(\text{Im} \tau)^{c_\eta(0)/2} \right| = -\frac{1}{4} \frac{|\text{CM}(d)|}{|\text{CM}(d)|} \left( \sum_{\eta \in \mathcal{L}^D / L} \sum_{m \geq 0} c_\eta(-m) \kappa_\eta(m) + c_\eta(0)(\Gamma'(1) + \log(2\pi)) \right).
\]

**Remark 15.**

(1) Note that the formula given in [24] is valid for Borcherds forms associated to lattices of general signature \((n,2)\). Here we have specialized the formulas to the cases under our consideration. Note also that in [24], the left-hand side of the formula has \( \Psi_\mathcal{F}(z) |y|^{c_\eta(0)/2} \) in place of \( \psi_\mathcal{F}(\tau)(\text{Im} \tau)^{c_\eta(0)/2} \), where \( z = x + iy \in K^+ \) and \( |y| = \sqrt{|y_1 y_2|} \). By a direct computation, we find that for \( z = z(\tau) \) given in 4, we have \( |y| = \text{Im} \tau \). Notice that in general, for any modular form \( \psi(\tau) \) of weight \( k \) on a Fuchsian subgroup \( \Gamma \) of \( \text{SL}(2,\mathbb{R}) \), we have \( |\psi(\gamma \tau)(\text{Im} \gamma \tau)^{k/2}| = |\psi(\tau)(\text{Im} \tau)^{k/2}| \) for any \( \tau \in \mathbb{H}^+ \) and \( \gamma \in \Gamma \). Thus, the left-hand side of the formula does not depend on the choice of representatives of the CM-points.

(2) Let \( \chi_d \) be the Kronecker character associated to the field \( \mathbb{Q}(\sqrt{d}) \) and

\[
\Lambda(s, \chi_d) = \left( \frac{\pi}{|d|} \right)^{-1+ s/2} \Gamma \left( \frac{1 + s}{2} \right) L(s, \chi_d).
\]
be the complete $L$-function associated to $\chi_d$. In [24], the term $\kappa_0(0)$ was given as

$$\kappa_0(0) = \frac{\Lambda'(1, \chi_d)}{\Lambda(1, \chi_d)}$$

under a certain assumption. (Note that our definition of $\Lambda(s, \chi_d)$ is different from that in [24].) Later on, we will prove that for the cases under our consideration, we have

$$\kappa_0(0) = 2\frac{\Lambda'(1, \chi_d)}{\Lambda(1, \chi_d)} + \sum_{p \mid D/(D,d)} \frac{p-1}{p+1} \log p + \sum_{p \mid N/(N,d)} \log p,$$

where the last two summations run over all prime divisors $p$ of $D/(D,d)$ and $N/(N,d)$, respectively.

(3) From the functional equation $\Lambda(s, \chi_d) = \Lambda(1-s, \chi_d)$ for $\Lambda(s, \chi_d)$, we deduce that

$$2\frac{\Lambda'(1, \chi_d)}{\Lambda(1, \chi_d)} = \log \frac{4\pi}{|d|} - \Gamma'(1) - 2\frac{L'(0, \chi_d)}{L(0, \chi_d)}.$$  

By the Chowla-Selberg formula, we have

$$e^{L'(0, \chi_d)/2L(0, \chi_d)} = \frac{1}{\sqrt{|d|}} \prod_{\alpha=1}^{|d|-1} \Gamma \left( \frac{\alpha}{|d|} \right) \chi_d(a) \mu_d/4A_d = \omega_d.$$  

This shows that the value of a suitable modular form of weight $k$ on $X_0^D(N)/W_{D,N}$ at a CM-point of discriminant $d$ will be an algebraic multiple of $\omega_d$, agreeing with the results of [26] and [37].

We now explain what the terms $\kappa_1(m)$ are. Recall that each CM-point $\tau$ of discriminant $d$ corresponds to an embedding $\phi : \mathbb{Q} \sqrt{d} \to B$ such that $\phi(\mathbb{Q} \sqrt{d}) \cap O = \phi(R_d)$, where $R_d$ is the imaginary quadratic order of discriminant $d$. To be more precise, $\tau$ is the common fixed point of $\phi(R_d)$ in the upper half-plane. Let $\lambda = \phi(\mathbb{Q} \sqrt{d})$. Then $\lambda$ is an element of positive norm in $L$ and the set $U = \lambda^⊥ = \{ \alpha \in V(Q) : \langle \lambda, \alpha \rangle = 0 \}$ is a negative 2-plane isomorphic to $\mathbb{Q} \sqrt{d}$ in the sense that there is an isomorphism $h : U \to \mathbb{Q} \sqrt{d}$ as vector spaces over $\mathbb{Q}$ and a negative rational number $c$ such that $c(\alpha, \beta) = tr_{\mathbb{Q} \sqrt{d}}(h(\alpha)\overline{h(\beta)})$ for all $\alpha, \beta \in U$.

Let $L_+ = L \cap \mathbb{Q} \lambda$ and $L_- = L \cap U$. We have

$$L_+ + L_- \subset L \subset L^⊥ \subset L^⊥_+ + L^⊥_-.$$  

For $\mu \in L^⊥_+/L_-$, let $\varphi_{\mu} : U \to \mathbb{C}$ be the characteristic function of $\mu + L_-$. Then for each $\mu \in L^⊥_+/L_-$, we have the incoherent Eisenstein series $E(\tau, s; \varphi_{\mu}, 1)$ of weight 1 [20] [21] [22] [24]. Write $\tau = u + iv$ and let

$$E(\tau, s; \varphi_{\mu}, 1) = \sum_{m} A_{\mu}(s, m, v)q^m, \quad q = e^{2\pi i \tau},$$  

be the Fourier expansion of $E(\tau, s; \varphi_{\mu}, 1)$. The Eisenstein series $E(\tau, s; \varphi_{\mu}, 1)$ vanishes at $s = 0$. Thus,

$$A_{\mu}(s, m, v) = b_{\mu}(m, v)s + O(s^2)$$  

Taking the derivative of the above expression and evaluating at $s$ we have

$$\kappa_\mu(m) := \begin{cases} \lim_{v \to \infty} b_\mu(m, v), & \text{if } m > 0, \\ \lim_{v \to \infty} (b_0(0, v) - \log v), & \text{if } m = 0 \text{ and } \mu = 0, \\ 0, & \text{else}. \end{cases}$$

(11)

Then the term $\kappa_\eta(m)$ in Schofer’s formula is defined by

$$\kappa_\eta(m) = \sum_{\mu \in L/(L_+ + L_-)} \sum_{x \in \eta_+ + \mu_+ + L_+} \kappa_{\eta_-, \eta_+}(m - \langle x, x \rangle/2),$$

(12)

where for $\mu \in L/(L_+ + L_-)$ and $\eta \in L^\vee / L$, we write $\mu = \mu_+ + \mu_-$ and $\eta = \eta_+ + \eta_-$ with $\mu_+, \eta_+ \in \mathbb{Q}\lambda$ and $\mu_-, \eta_- \in U$. The terms $\kappa_\eta(m)$ look very complicated, but nonetheless are computable using the fact that $A_\mu(s, m, v)q^m$ can be written as a product of local Whittaker functions $\mathcal{W}_\mu(s, \varphi_{\mu, p})$, which can be computed using formulas in [22][32]. Here we briefly describe a general strategy to compute $A_\mu(s, m, v)$ and $\kappa_\mu(m)$ efficiently, following [13][22].

In general, for $\mu \in L^\vee / L_-$, we have $A_\mu(s, m, v) = 0$ unless $\langle \mu, \mu \rangle/2 - m \in \mathbb{Z}$ and when $\langle \mu, \mu \rangle/2 - m \in \mathbb{Z}$ holds, we have

$$A_\mu(s, m, v)q^m = \delta_{\mu, m}v^{s/2} + W_{m, \infty}(\tau, s) \prod_{p < \infty} W_{m, p}(s, \varphi_{\mu, p}),$$

where

$$\delta_{\mu, m} = \begin{cases} 1, & \text{if } \mu = 0 \text{ and } m = 0, \\ 0, & \text{else}, \end{cases}$$

and $W_{m, \infty}(\tau, s)$ and $W_{m, p}(s, \varphi_{\mu, p})$ are the local Whittaker factors at $\infty$ and $p$, respectively. (See [20] Section 2.) Let $\Delta$ be the discriminant of the lattice $L_\mu$. When a prime $p$ does not divide $\Delta$ and the $p$-adic valuation $v_p(m)$ is zero, Equation (4.4) and Theorems 4.3 and 4.4 of [22] yield

$$W_{m, p}(s, \varphi_{\mu, p}) = \gamma_p(1 - \chi_d(p)p^{1-s}),$$

where $\gamma_\infty$ and $\gamma_p$ are certain explicit constants that do not have any effect on the calculation since $\gamma_\infty \prod_p \gamma_p = 1$. Therefore, assuming $m > 0$, letting

$$S_{m, \mu} = \{ p : p|\Delta \text{ or } v_p(m) > 0 \},$$

(13)

and using the formula for $W_{m, \infty}$ in Proposition 2.3 of [22], we find

$$A_\mu(m, s, v) = -\frac{2\pi}{L(s + 1, \chi_d)} \prod_{p \in S_{m, \mu}} W_{m, p}(s, \varphi_{\mu, p}) \frac{W_{m, p}(0, \varphi_{\mu, p})}{1 - \chi_d(p)p^{-1-s}}.$$ 

As $A_\mu(m, 0, v) = 0$, there exists at least a prime $p'$ in $S_{m, \mu}$ such that $W_{m, p'}(0, \varphi_{\mu, p})$. Taking the derivative of the above expression and evaluating at $s = 0$, we obtain the following lemma.

**Lemma 16.** Assume that $m > 0$ and let all the notations be given as in the discussion. We have

$$\kappa_\mu(m) = -\mu_d \sqrt{d} \frac{\prod_{p \in S_{m, \mu}} W_{m, p}(0, \varphi_{\mu, p})}{h_d \prod_{p \in S_{m, \mu}} \frac{W_{m, p}(0, \varphi_{\mu, p})}{1 - \chi_d(p)p^{-1}}},$$

where $\mu_d$ and $h_d$ denote the number of roots of unity and the class number of $\mathbb{Q}(\sqrt{d})$, respectively.
Then we have (See [24, Lemma 2.20].)
so that

Let all the notations be given as above. We have

Lemma 17.

Let \( \Delta \) be the discriminant. From this, we deduce the following lemma.

Lemma 18.

In general, the discriminant \( \Delta \) of \( L_\infty \) may not be exactly \(|d|\). Let

\[
S = \{ p : \, p|(\Delta/d) \}.
\]

Then we have

\[
A_0(s, 0, v) = v^{s/2} - v^{-s/2} \frac{\Lambda(s, \chi_d)}{\Lambda(s + 1, \chi_d)} \prod_{p \in S} \frac{(1 - \chi_d(p)p^{-s})W_{0,p}(s, \varphi_{0,p})}{1 - \chi_d(p)p^{-1-s}}.
\]

Let \( G(s) \) denote the product on the right. Since \( A_0(0, 0, v) \) is identically 0, we must have \( G(0) = 1 \). From this, we deduce the following lemma.

Lemma 17. Let all the notations be given as above. We have

\[
\kappa_0^{-}(0) = 2 \frac{\Lambda'(1, \chi_d)}{\Lambda(1, \chi_d)} - \frac{d}{ds} \log G(s)\bigg|_{s=0}.
\]

We now determine \( G(s) \) for the cases under our consideration. In the following lemma, for a prime \( p \), we let \( L_p = L_\infty \otimes \mathbb{Z}_p \).

Lemma 18. Let all the notations be given as in the preceding discussion. Assume that the level \( N \) of the Eichler order \( O \) is squarefree and that \( d < 0 \) is a fundamental discriminant.

1. Let \( p \) be an odd prime. Then there exists a basis \( \{ \ell_1, \ell_2 \} \) for \( L_p \) and \( \epsilon_1, \epsilon_2 \in \mathbb{Z}_p \) with \( \epsilon_1\epsilon_2 = -d \) such that the Gram matrix \( (\langle \ell_i, \ell_j \rangle) \) is equal to

\[
\begin{cases}
\left( \begin{array}{cc}
\epsilon_1 & 0 \\
0 & \epsilon_2
\end{array} \right), & \text{if } p|(DN, d) \text{ or if } p \nmid DN, \\
\left( \begin{array}{cc}
p & \epsilon_1 \\
0 & \epsilon_2
\end{array} \right), & \text{if } p|DN \text{ but } p \nmid d.
\end{cases}
\]

2. Assume that \( d \equiv 0 \mod 4 \). Then there exists a basis \( \{ \ell_1, \ell_2 \} \) for \( L_2 \) and \( \epsilon_1, \epsilon_2 \in \mathbb{Z}_2 \) with \( \epsilon_1\epsilon_2 = -d/4 \) such that the Gram matrix is

\[
2 \left( \begin{array}{cc}
\epsilon_1 & 0 \\
0 & \epsilon_2
\end{array} \right).
\]

3. Assume that \( d \equiv 1 \mod 8 \) (and \( 2 \nmid D \)). Then there exists a basis \( \{ \ell_1, \ell_2 \} \) for \( L_2 \) and \( \epsilon \in \mathbb{Z}_2^\times \) such that the Gram matrix is

\[
\begin{cases}
2\epsilon \left( \begin{array}{cc}
0 & 1 \\
1 & 0
\end{array} \right), & \text{if } 2|N, \\
\epsilon \left( \begin{array}{cc}
0 & 1 \\
1 & 0
\end{array} \right), & \text{if } 2 \nmid N.
\end{cases}
\]
(4) Assume that $d \equiv 5 \mod 8$ (and $2 \nmid N$). Then there exists a basis $\{\ell_1, \ell_2\}$ for $L_2$ and $e \in \mathbb{Z}_2^\times$ such that the Gram matrix is

$$\begin{cases}
2e \begin{pmatrix}
2 & 1 \\
1 & 2
\end{pmatrix} & \text{if } 2 \mid D, \\
e \begin{pmatrix}
2 & 1 \\
1 & 2
\end{pmatrix} & \text{if } 2 \nmid D,
\end{cases}$$

Proof. Assume that $p$ is an odd prime. Consider the case when $p$ divides $DN$ first. There exists a basis $\{e_1, e_2, e_3\}$ for $L \otimes \mathbb{Z}_p$ such that

$$(\langle e_i, e_j \rangle) = \begin{pmatrix}
2\mu_1 & 0 & 0 \\
0 & 2\mu_2 & 0 \\
0 & 0 & 2\mu_1\mu_2
\end{pmatrix},$$

where $\mu_1$ and $\mu_2$ are elements in $\mathbb{Z}_p^\times$ with the property that the Hilbert symbol $(-\mu_1, -\mu_2)_p$ is 1 or -1 depending on whether $p \mid N$ or $p \mid D$.

Assume that $\lambda = c_1e_1 + c_2e_2 + c_3e_3$. If $p \mid d$, then we have $p \mid c_1$ and at least one of $c_2$ and $c_3$ must be in $\mathbb{Z}_p^\times$. Without loss of generality, we assume that $c_2 \in \mathbb{Z}_p^\times$. Then $L_p$ is spanned by $-c_2\mu_2e_1 + (c_1/p)\mu_1e_2$ and $c_3\mu_1e_2 - c_2e_3$. The Gram matrix of $L_p$ with respect to this basis has determinant $-(2c_2\mu_1\mu_2)^2d$. It follows that there is a basis $\{\ell_1, \ell_2\}$ for $L_p$, such that $(\langle \ell_i, \ell_j \rangle) = \begin{pmatrix} \ell_i \ell_j \end{pmatrix}$ with the properties $\ell_1, \ell_2 \in \mathbb{Z}_p$ and $\ell_1\ell_2 = -d$.

If $p \nmid d$, then $p \nmid c_1$. We find that $L_p$ is spanned by $-c_2\mu_2\mu_2e_2 + c_1\mu_1e_2$ and $-c_3\mu_2p + c_1e_3$. The Gram matrix of $L_p$ with respect to this basis is inside $pM(2, \mathbb{Z}_p)$ and its determinant is $-(2c_1\mu_1\mu_2p)^2d$. It follows that there exists a basis $\{\ell_1, \ell_2\}$ for $L_p$ such that $(\langle \ell_i, \ell_j \rangle) = \begin{pmatrix} \ell_i \ell_j \end{pmatrix}$ with $\ell_1, \ell_2 \in \mathbb{Z}_p$ and $\ell_1\ell_2 = -d$. The proof of the case $p \nmid DN$ is similar and is omitted.

Now consider the case $p = 2$. If $2 \nmid DN$, then $O \otimes \mathbb{Z}_2$ is isomorphic to $M(2, \mathbb{Z}_2)$. Thus, we may assume that $L \otimes \mathbb{Z}_2$ is isomorphic to $\{\alpha \in M(2, \mathbb{Z}_2) : tr(\alpha) = 0\}$ so that $e_1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$, $e_2 = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$, and $e_3 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ form a basis for $L \otimes \mathbb{Z}_2$. Let $c_1, c_2, c_3$ be the elements in $\mathbb{Z}_2$ such that

$$c_1e_1 + c_2e_2 + c_3e_3 = \begin{cases}
\lambda, & \text{if } d \equiv 1 \mod 4, \\
\lambda/2, & \text{if } d \equiv 0 \mod 4.
\end{cases}$$

When $d \equiv 1 \mod 4$, the element $\lambda$ satisfies $(1 + \lambda)/2 \in O \otimes \mathbb{Z}_2$, which implies that $2 \nmid c_1$ and $2|c_2, c_3$. Therefore, the lattice $L_2 = L_- \otimes \mathbb{Z}_2$ is spanned by $-(c_2/2)e_1 + c_1e_3$ and $-(c_3/2)e_1 + c_1e_2$. The Gram matrix relative to this basis is

$$\begin{pmatrix}
-c_2^2/2 & -c_2c_3/2 \\
-c_2c_3/2 & -c_3^2/2
\end{pmatrix}$$

with determinant $-c_2^2(c_1^2 + c_2c_3) \equiv -d \mod 8$. By Lemma 8.4.1 of [10], there is a basis $\{\ell_1, \ell_2\}$ for $L_2$ and $e \in \mathbb{Z}_2^\times$ such that the Gram matrix is

$$\begin{cases}
e \begin{pmatrix}
0 & 1 \\
1 & 0
\end{pmatrix}, & \text{if } d \equiv 1 \mod 8, \\
e \begin{pmatrix}
2 & 1 \\
1 & 2
\end{pmatrix}, & \text{if } d \equiv 5 \mod 8.
\end{cases}$$

If $d \equiv 0 \mod 4$, then $c_2$ and $c_3$ cannot be both even since $-c_1^2 - c_2c_3 = -d/4 \equiv 1, 2 \mod 4$. Assume that $2 \nmid c_2$. Then $L_2$ is spanned by $c_2e_1 - 2c_1e_3$ and $c_2e_2 - c_3e_3$. The
Using the notations in Section 4.2 of [22], we have

\[ H \equiv -2c_2^2 \quad 2c_1c_2 \quad 2c_1c_2 \quad 2c_2c_3. \]

It follows from Lemma 8.4.1 of [10] that there exists a basis \( \{ \ell_1, \ell_2 \} \) for \( L_2 \) such that the Gram matrix is

\[
    \begin{pmatrix}
    2 & \epsilon_1 \\
    \epsilon_2 & 0 \\
    \end{pmatrix}
\]

with \( \epsilon_1, \epsilon_2 \in \mathbb{Z}_2 \) and \( \epsilon_1 \epsilon_2 = -d/4 \). This proves the case \( 2 \nmid DN \).

The proof of the case \( 2|DN \) is similar. We remark that when \( 2|N \), we have \( \mathcal{O} \otimes_\mathbb{Z} \mathbb{Z}_2 \approx (\mathbb{Z}_2/2 \mathbb{Z}_2)^2 \) and when \( 2|D \), we have \( B \otimes \mathbb{Q}_2 \approx \left( -\frac{1}{4} \right) \) and the maximal order in \( \left( -\frac{1}{4} \right) \) is \( \mathbb{Z}_2 + \mathbb{Z}_2 I + \mathbb{Z}_2 J + \mathbb{Z}_2 (1 + I + J + IJ)/2 \). The rest of the proof is similar to that in the other cases and is omitted. \( \square \)

**Corollary 19.** Let all the notations and assumptions be given as before. Let

\[ r = \prod_{p|DN/(DN, d)} p. \]

Then the Gram matrix of \( L_- \) is equivalent to \( -rM \) for some positive definite integral matrix \( M \) of determinant \( |d| \). In particular, the discriminant of \( L_- \) is \( r^2|d| \).

**Lemma 20.** Assume that \( N \) is squarefree and \( d < 0 \) is a fundamental discriminant. Let \( \chi_d, \lambda(s, \chi_d), \lambda, L^+, \) and \( L_- \) be defined as above. Let \( \kappa^{-}_\mu(m) \) and \( \kappa_\eta(m) \) be defined as in (11) and (12), respectively. Then we have

\[
\kappa_0(0) = \kappa_0(0) = 2 \frac{\Lambda(1, \chi_d)}{\Lambda(1, \chi_d)} + \sum_{p|D/(D, d)} \frac{p-1}{p+1} \log p + \sum_{p|(N/(N, d))} \log p,
\]

where the two sums run over prime divisors of \( D/(D, d) \) and \( N/(N, d) \), respectively.

**Proof.** Consider the case when an odd prime \( p \) divides \( DN/(DN, d) \), i.e., \( p|DN \) but \( p \nmid D \). By Lemma 18, the Gram matrix of \( L_p = L_- \otimes_\mathbb{Z} \mathbb{Z}_p \) is equivalent to \( p \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \) for some \( \epsilon_1, \epsilon_2 \in \mathbb{Z}_p \) with \( \epsilon_1 \epsilon_2 = -d \). We shall apply Theorem 4.3 of [22] with \( \mu = 0 \) and \( m = 0 \). Using the notations in Section 4.2 of [22], we have \( H_\mu = \{ 1, 2 \} \), \( K_0(\mu) = \infty \),

\[
L_\mu(k) = \begin{cases} 
\{ 1, 2 \} & \text{if } k \text{ is even}, \\
\emptyset & \text{if } k \text{ is odd},
\end{cases}
\]

\[
d_\mu(k) = 1 \text{ for all } k, \quad \epsilon_\mu(k) = \chi_d(p)^{k-1}, \quad t_\mu(m) = 0, \quad \text{and } a_\mu(m) = \infty. \]

Thus, the combination of (4.4) and Theorem 4.3 of [22] yields

\[
W_{0,p}(s, \varphi_0) = \gamma_p p^{-1} \left( 1 + \frac{1}{p} \right) \sum_{k=1}^{\infty} p^{\chi_d(p)^{k-1}p^{-s}} = 1 + (p - 1) \frac{p^{-s}}{1 - \chi_d(p)p^{-s}}.
\]

That is

\[
W_{0,p}(s, \varphi_0) = \gamma_p \frac{1 - \chi_d(p)^{1-s}}{1 - \chi_d(p)p^{-s}} \left( 1 + \frac{p - 1 - \chi_d(p)}{p - \chi_d(p)p^{-s}} \right).
\]

For the case \( 2|DN/(DN, d) \), i.e., \( 2|DN \) and \( d \equiv 1 \mod 4 \), we use the results in Section 4.3 of [22]. Consider the case \( d \equiv 1 \mod 8 \) and \( 2|N \) first. By Lemma 18, the Gram matrix of \( L_2 \) is equivalent to \( 2 \kappa (\frac{1}{\ell} \frac{1}{0}) \). Following the notations in Section 4.3 of [22], we have
$H_\mu = N_\mu = \emptyset$, $M_\mu = \{1\}$, $L_\mu(k) = \emptyset$, $d_\mu(k) = p_\mu(k) = \epsilon_\mu(k) = \delta_\mu(k) = 1$ for all $k \geq 1$, $K_0(\mu) = \infty$, and $t_\mu = \nu = 0$. Thus, Theorem 4.4 and (4.4) of [22] yield

\begin{equation}
W_{0,2}(s, \varphi_{0,p}) = \frac{\gamma_2}{2} \left( 1 + 2^{-s} + 2^{-2s} + \cdots \right) = \frac{1 - 2^{-1-s}}{1 - 2^{-s}} \cdot \frac{1}{2 - 2^{-s}}.
\end{equation}

For the case $d \equiv 5 \pmod{8}$ and $2 | D$, Lemma 16 shows that the Gram matrix is equivalent to $2 \epsilon \left( \frac{1}{2} \right)$ for some $\epsilon \in \mathbb{Z}_2^\times$. In this case, we have $H_\mu = M_\mu = \emptyset$, $N_\mu = \emptyset$, $L_\mu(k) = \emptyset$, $d_\mu(k) = \epsilon_\mu(k) = \delta_\mu(k) = 1$ for $k \geq 1$, $p_\mu(k) = (-1)^{k-1}$, $K_0(\mu) = \infty$, and $t_\mu = \nu = 0$. Then Theorem 4.4 of [22] shows that

\begin{equation}
W_{0,2}(s, \varphi_{0,p}) = \frac{\gamma_2}{2} \left( 1 + 2^{-s} - 2^{-2s} + 2^{-3s} - \cdots \right) = \frac{1 - 2^{-1-s}}{1 - 2^{-s}} \cdot \frac{1 + 2^{1-s}}{2 + 2^{-s}}.
\end{equation}

From (14), (15), (16), and (17), we see that

$$A_0(s, 0, v) = v^{s/2} - v^{-s/2} \frac{\Lambda(s, \chi_d)}{\Lambda(s + 1, \chi_d)} \prod_{p|D/(D,d)} \frac{1 + p^{1-s}}{p + p^{-s}} \prod_{p|N/(N,d)} \frac{1 + (p - 2)p^{-s}}{p - p^{-s}}.$$ 

By Lemma 17

$$\kappa_0^-(0) = 2 \frac{\Lambda'(1, \chi_d)}{\Lambda(1, \chi_d)} - \sum_{p|D/(D,d)} \left( \frac{-p^{1-s} \log p}{1 + p^{1-s}} - \frac{-p^{-s} \log p}{p + p^{-s}} \right) \bigg|_{s=0}$$

$$- \sum_{p|N/(N,d)} \left( \frac{-}(p - 2)p^{-s} \log p}{1 + (p - 2)p^{-s}} - \frac{p^{-s} \log p}{p - p^{-s}} \right) \bigg|_{s=0}$$

$$= 2 \frac{\Lambda'(1, \chi_d)}{\Lambda(1, \chi_d)} + \sum_{p|D/(D,d)} \frac{p - 1}{p + 1} \log p + \sum_{p|N/(N,d)} \log p$$

and the proof of the lemma is complete.

\[\square\]

**Example 21.** Let $\psi_{F,J}(\tau)$ and $\psi_{F,s}(\tau)$ be the Borcherds forms given in Proposition 14. In this example, we shall utilize Lemmas 16 and 20 to determine the absolute values of $\psi_{F,J}(\tau)$ at the CM-point of discriminant $-4$ and that of $\psi_{F,s}(\tau)$ at the CM-point of discriminant $-3$.

Let $B = \left( -\frac{1}{3} \right)$, $O = \mathbb{Z} + \mathbb{Z}I + \mathbb{Z}J + \mathbb{Z}IJ$, and the embedding $\iota : B \rightarrow M(2, \mathbb{R})$ be chosen as in Section 2. Choose $\lambda = I$. Then $\phi : \iota \rightarrow I$ defines an optimal embedding relative to $(O, \mathbb{Z}[i])$ and the fixed point $\tau_d$ of $\iota(\phi(I))$ in the upper half-plane is a CM-point of discriminant $d = -4$. By Theorem B, Lemma 20 and (10), we have

$$\log |\psi_{F,J}(\tau_d)(\Im \tau_d)^4| = -\frac{1}{4} \left( 2\kappa_0(3) + 8\kappa_0(0) + 8\Gamma'(1) + 8 \log(2\pi) \right)$$

$$= -\frac{1}{2} \kappa_0(3) - 4 \frac{\Lambda'(1, \chi_d)}{\Lambda(1, \chi_d)} - \log 3 - 2\Gamma'(1) - 2 \log(2\pi)$$

$$= -\frac{1}{2} \kappa_0(3) + 4 \frac{\Lambda'(0, \chi_d)}{\Lambda(0, \chi_d)} - \log 3 + 2 \log |d| - 2 \log(8\pi^2).$$

The term that needs some work is $\kappa_0(3)$.

We have $L_+ = \mathbb{Z}I$ and $L_- = \mathbb{Z}J + \mathbb{Z}IJ$. Thus, $L = L_+ + L_-$ and by (12), we have

$$\kappa_0(3) = \sum_{x \in L_+} \kappa_0^-(3 - \langle x, x \rangle/2) = \kappa_0^-(3) + 2\kappa_0^-(2).$$
With respect to the basis \{J, JJ\}, the Gram matrix of \(L_-\) is \(\begin{pmatrix} -6 & 0 \\ 0 & -1 \end{pmatrix}\). Thus, the sets \(S_{m,\mu}\) in \([13]\) is \{2, 3\} for both \(\kappa^{-}_0(3)\) and \(\kappa^{-}_0(2)\). Using results in Section 4 of \([22]\), we find that
\[
W_{3,2}(s, \varphi_{0,2}) = \frac{1}{2} (1 - 2^{-2s}), \quad W_{3,3}(s, \varphi_{0,3}) = \frac{1}{3} (1 + 2 \cdot 3^{-s} + 3^{-2s}),
\]
and
\[
W_{2,2}(s, \varphi_{0,2}) = \frac{1}{2} (1 + 2^{-3s}), \quad W_{2,3}(s, \varphi_{0,3}) = \frac{1}{3} (1 - 3^{-s}).
\]
Therefore, by Lemma \([16]\)
\[
\kappa^{-}_0(3) = -8 \log 2, \quad \kappa^{-}_0(2) = -2 \log 3,
\]
and \(\kappa_0(3) = -8 \log 2 - 4 \log 3\). It follows that
\[
|\psi_{\omega}(\tau_d)(\text{Im } \tau_d)^4| = 48 \cdot \frac{|d|^2}{64\pi^4} e^{4L'(0, \chi_d)/L(0, \chi_d)}.
\]
We next determine the value of \(\psi_{\omega}(\tau)\) at the CM-point of discriminant \(d = -3\). Choose \(\lambda = 3I - J + JJ\) so that \(\phi : \sqrt{-3} \to \lambda\) defines an optimal embedding of discriminant \(-3\). By Theorem \([8]\) Lemma \([20]\) and \([10]\) again, we have
\[
\log |\psi_{\omega}(\tau_d)(\text{Im } \tau_d)^6| = -\frac{1}{2} \kappa_0(1) - \frac{\Lambda'(1, \chi_d)}{\Lambda(1, \chi_d)} \log 2 - 2\pi - 2 \log(2\pi)
\]
\[
= -\frac{1}{2} \kappa_0(1) + 6 \frac{L'(0, \chi_d)}{L(0, \chi_d)} - 2 \log 2 + 3 \log |d| - 3 \log(8\pi^2).
\]
By Corollary \([19]\), the lattice \(L_-\) has discriminant 12 and its Gram matrix must be equivalent to \(\begin{pmatrix} -1 & 2 \\ -2 & -1 \end{pmatrix}\). Since the discriminant of the lattice \(L_+ + L_-\) is equal to that of \(L\), \(L/(L_+ + L_-)\) is trivial. Consequently,
\[
\kappa_0(1) = \sum_{x \in \mathbb{Z}_2} \kappa^{-}_0(1 - \langle x, x \rangle/2) = \kappa^{-}_0(1).
\]
The set \(S_{m,\mu}\) in \([13]\) is \{2, 3\} for \(\kappa^{-}_0(1)\). Using Theorems 4.3 and 4.4 of \([22]\), we find
\[
W_{1,2}(s, \varphi_{0,2}) = \frac{1}{2} (1 - 2^{-s}), \quad W_{1,3}(s, \varphi_{0,3}) = \frac{1}{3} (1 + 3^{-s}).
\]
Then, Lemma \([16]\) yields
\[
\kappa^{-}_0(1) = -6\sqrt{3} \cdot \frac{\log 2}{3} \cdot \frac{2}{\sqrt{3}} = -4 \log 2.
\]
Finally, we arrive at
\[
|\psi_{\omega}(\tau_d)(\text{Im } \tau_d)^6| = 2 \cdot \frac{|d|^3}{512\pi^6} e^{6L'(0, \chi_d)/L(0, \chi_d)}.
\]
**Corollary 22.** The absolute values of the constants \(C_1\) and \(C_2\) in \([8]\) and \([9]\) are
\[
|C_1| = \frac{12}{\pi^6} e^{4L'(0, \chi_{-1})/L(0, \chi_{-1})}, \quad |C_2| = \frac{27(1 + \sqrt{3})^6}{256\pi^6} e^{6L'(0, \chi_{-3})/L(0, \chi_{-3})},
\]
respectively.

**Proof.** The CM-point of discriminant \(-4\) in the example above is \(\tau_{-4} = i\). According to our choice of \(s(\tau)\) in Proposition \([5]\) we have \(s(i) = 0\). Therefore, the right-hand side of \([8]\) is simply \(C_1\). Then \([18]\) gives us the absolute value of \(C_1\). The determination of \(|C_2|\) is similar. \(\square\)
Remark 23. The values of $|C_1|$ and $|C_2|$ can also be determined by considering the values of the Borcherds forms at the CM-point $\tau_{-24}$ of discriminant $-24$. At the point $\tau_{-24}$, the functions $s(\tau)$ and $t(\tau)$ take value 1. Thus, the right-hand sides of (\ref{eq:psiF}) and (\ref{eq:psiF2}) can be expressed in terms of Gamma values using Gauss’ formula.

Example 24. Consider the case $d = -163$. By Theorem B and Lemma 20 we have

$$\log |\psi_{F_1}(\tau_d)(\text{Im } \tau_d)^4| = -\frac{1}{2} \kappa_0(3) + 4 \frac{L'(0, \chi_d)}{L(0, \chi_d)} - \log 3 - \frac{2}{3} \log 2 + 2 \log |d| - 2 \log (8\pi^2).$$

On Page 851 of \cite{13}, it is computed that

$$\kappa_0(3) = -\frac{40}{3} \log 2 - 4 \log 3 - 4 \log 5 - 4 \log (11) - 4 \log(17).$$

Thus,

$$|\psi_{F_1}(\tau_d)(\text{Im } \tau_d)^4| = 2^6 \cdot 3 \cdot 5^2 \cdot 11^2 \cdot 17^2 \cdot \frac{|d|^2}{64\pi^4} e^{4L'(0, \chi_d)/L(0, \chi_d)}.$$

We now give the values of the Borcherds forms $\psi_{F_1}(\tau)$ and $\psi_{F_2}(\tau)$ at various CM-points. The computation is done using Magma \cite{7}. (The use of Magma is not essential. We use Magma only because it has built-in functions for computation about quaternion algebras.) The Magma code is available as an accompanying file to this paper.

Lemma 25. For a fundamental discriminant $d < 0$ appearing in Theorem 2 let $\tau_d \in \mathbb{H}^+$ be a CM-point of discriminant $d$, and

$$\omega_d = e^{L'(0) / 2L(0)} = \frac{1}{\sqrt{|d|}} \prod_{a=1}^{|d|-1} \Gamma \left( \frac{\chi_d(a)|d|}{4|d|} \right).$$

Let $A_d$ be the number such that

$$|\psi_{F_1}(\tau_d)(\text{Im } \tau_d)^4| = A_d \frac{|d|^2}{64} \left( \frac{\omega_d}{\sqrt{\pi}} \right)^8.$$

Then we have

| $d$ | $A_d$ | $d$ | $A_d$ | $d$ | $A_d$ |
|-----|------|-----|------|-----|------|
| $-4$ | $2^4 \cdot 3$ | $-4$ | $2^4 \cdot 3^2 \cdot 5^2$ | $-4$ | $2^4 \cdot 3 \cdot 5^2 \cdot 17^2$ |
| $-24$ | $2^4 \cdot 3^2$ | $-24$ | $2^4 \cdot 3 \cdot 5^2$ | $-24$ | $2^4 \cdot 3 \cdot 5^2 \cdot 23^2 \cdot 29$ |
| $-120$ | $2^4 \cdot 3^3 \cdot 5$ | $-120$ | $2^4 \cdot 3 \cdot 5^2 \cdot 11$ | $-120$ | $2^4 \cdot 3 \cdot 5^2 \cdot 17^2 \cdot 29^2$ |
| $-52$ | $2^4 \cdot 3 \cdot 5^2$ | $-52$ | $2^4 \cdot 3^2 \cdot 5^2 \cdot 11^2$ | $-52$ | $2^4 \cdot 3 \cdot 5^2 \cdot 11^2 \cdot 17^2$ |

Also, let $B_d$ be the number such that

$$|\psi_{F_2}(\tau_d)(\text{Im } \tau_d)^6| = B_d \frac{|d|^3}{512} \left( \frac{\omega_d}{\sqrt{\pi}} \right)^{12}.$$
We have

| d    | B_d   | d    | B_d   | d    | B_d   |
|------|-------|------|-------|------|-------|
| −3   | 2     | −19  | 2 ⋅ 3^2 | −67  | 2 ⋅ 3^2 ⋅ 7^2 ⋅ 11^2 |
| −84  | 2^4 ⋅ 7 | −168 | 2^3 ⋅ 7 ⋅ 11^2 | −372 | 2^4 ⋅ 7^2 ⋅ 19^2 ⋅ 31 |
| −40  | 2^3 ⋅ 3^2 | −228 | 2^6 ⋅ 7^2 ⋅ 19 | −408 | 2^3 ⋅ 7^2 ⋅ 11^2 ⋅ 31^2 |
| −51  | 2 ⋅ 7^2 | −123 | 2 ⋅ 7^2 ⋅ 19^2 | −267 | 2 ⋅ 7^2 ⋅ 31^2 ⋅ 43^2 |

5. Proof of Theorem [2]

In this section, we shall convert informations from Lemma [25] into special-value formulas for hypergeometric functions.

We retain our choices of B, O, t, the fundamental domain, and etc. from Section [2]. In the following discussion, we let s be the Hauptmodul of X_0^+(1)/W_0 that takes values 0, 1, and ∞ at the CM-points of discriminants −4, −24, and −3, respectively. According to the choice of the Fundamental domain in Section [2] these CM-points are represented by (i/2, (√6−√2)i/2), and (−1+i)/(1+√3), respectively. Let also t = 1/s. For a CM-point τ_d of a fundamental discriminant d < 0 inside the fundamental domain, we let φ : Q(√d) ↪ B be the corresponding optimal embedding and assume that φ(√d) = a_1 I + a_2 J + a_3 IJ. Then we have

\[
τ_d = \frac{a_2 \sqrt{3} + \sqrt{d}}{a_1 + a_3 \sqrt{3}}. \tag{22}
\]

We first recall a technical lemma from [35].

**Lemma 26 ([35] Lemma 5).** If s(τ_d) takes a value in the line segment [0, 1], then a_2 = 0. If s(τ_d) takes a value in [1, ∞), then a_1 = 3a_3. If s(τ_d) takes a negative value, then a_2 = −a_3.

Recall that ψ_{F_j}(τ) and ψ_{F_δ}(τ) are the Borcherds forms defined in (8) and (9), respectively.

**Proposition 27.** Assume that −1 < s(τ_d) < 1. Let A_d be the real number such that (20) holds. Then we have

\[
2F_1 \left( \frac{1}{24}, \frac{5}{24}; \frac{3}{4}, s(τ_d) \right)^8 = \frac{A_d}{2^{12} \cdot 3^4} (a_1 + \sqrt{|d|})^4 \left( \frac{ω_d}{ω_{−4}} \right)^8 \] \tag{23}

and

\[
3F_2 \left( \frac{1}{3}, \frac{1}{2}, \frac{2}{3}, \frac{3}{4}, \frac{5}{4}; s(τ_d) \right)^4 = \frac{3^2 A_d}{2^{10} |s(τ_d)|} (a_2^2 + a_3^2)^2 ω_δ. \tag{24}
\]

Assume that −1 < t(τ_d) < 1. Let B_d be the real number such that (21) holds. Then we have

\[
2F_1 \left( \frac{1}{24}, \frac{7}{24}; \frac{5}{6}, t(τ_d) \right)^{12} = \frac{B_d}{2^6 \cdot 3^8} \left( \frac{ω_d}{ω_{−3}} \right)^{12} \times \begin{cases} ((a_2 + 2a_3)\sqrt{3} + \sqrt{|d|})^6, & \text{if } t(τ_d) > 0, \\ ((a_1 - 2a_3)\sqrt{3} + \sqrt{|d|})^6, & \text{if } t(τ_d) < 0, \end{cases} \tag{25}
\]
Combining (8), (20), (22), and Corollary 22, we find
\[
F(s_d) = \sqrt{12} \omega_d^{2} F_1(s_d) \left| \frac{\tau_d - i}{\tau_d + i} \right|^{1/4} = \sqrt{12} \omega_d^{2} F_1(s_d) \left| \frac{\tau_d - i}{\tau_d + i} \right|^{1/4}.
\]
Combining this with (23), we obtain
\[
F_1(s_d)^8 F_2(s_d)^8 = 2^4 \cdot 3^2 \cdot \omega_d^{16} \frac{F_1(s_d)^{16}}{s_d^2} \frac{(a_1 - \sqrt{|d|})^{16}}{3^4 (a_2^2 + a_3^2)^4} = \frac{A_d^2}{2^{20} \cdot 3^4 \cdot s_d^2} \frac{(a_1 + \sqrt{|d|})^{16} (a_1 - \sqrt{|d|})^{16}}{(a_2^2 + a_3^2)^4} \omega_d^{16} = \frac{3^4 A_d^2 (a_2^2 + a_3^2)^4}{2^{20} s_d^2} \omega_d^{16}.
\]
Simplifying the equality, we get (23).

\[
F(s_d) = \sqrt{12} \omega_d^{2} F_1(s_d) \left| \frac{\tau_d - i}{\tau_d + i} \right|^{1/4} = \sqrt{12} \omega_d^{2} F_1(s_d) \left| \frac{\tau_d - i}{\tau_d + i} \right|^{1/4}
\]
Combining this with (23), we obtain
\[
F_1(s_d)^8 F_2(s_d)^8 = 2^4 \cdot 3^2 \cdot \omega_d^{16} \frac{F_1(s_d)^{16}}{s_d^2} \frac{(a_1 - \sqrt{|d|})^{16}}{3^4 (a_2^2 + a_3^2)^4} = \frac{A_d^2}{2^{20} \cdot 3^4 \cdot s_d^2} \frac{(a_1 + \sqrt{|d|})^{16} (a_1 - \sqrt{|d|})^{16}}{(a_2^2 + a_3^2)^4} \omega_d^{16} = \frac{3^4 A_d^2 (a_2^2 + a_3^2)^4}{2^{20} s_d^2} \omega_d^{16}.
\]
Simplifying the equality, we get (23).

Similarly, we write \( t_d = t(\tau_d) \), and
\[
G_1(t) = 2 F_1 \left( \frac{1}{16} \frac{17}{6} ; \frac{5}{6} ; t \right), \quad G_2(t) = 2 F_1 \left( \frac{5}{24} \frac{11}{24} \sqrt{2} ; \frac{7}{6} ; t \right).
\]
Then \( G_1(t) G_2(t) = 3 F_2(1/4, 1/2, 3/4; 5/6, 7/6; t) \). Let \( C' = e^{-2\pi i/8} \sqrt{2} \omega_{-3}^{2} \). We have
\[
\frac{C'_d^4}{G_1(t_d)} = \frac{\tau_d - \tau_{-3}}{\tau_d - \tau_{-3}}, \quad \tau_{-3} = 1 + i, \quad \tau = 1 + \sqrt{3}.
\]
Using
\[
\left| \frac{\tau_d - \tau_{-3}}{\tau_d - \tau_{-3}} \right|^2 = \frac{3(a_1 + a_2 - a_3) - \sqrt{|d|}}{3(a_1 + a_2 - a_3) + \sqrt{|d|}},
\]
\[
\left| 1 - \frac{\tau_d - \tau_{-3}}{\tau_d - \tau_{-3}} \right|^2 = \frac{2}{1 + \sqrt{3} \sqrt{3(a_1 + a_2 - a_3) + \sqrt{|d|}}},
\]
and
\[
F_1(s_d)^8 F_2(s_d)^8 = 2^4 \cdot 3^2 \cdot \omega_d^{16} \frac{F_1(s_d)^{16}}{s_d^2} \frac{(a_1 - \sqrt{|d|})^{16}}{3^4 (a_2^2 + a_3^2)^4} = \frac{A_d^2}{2^{20} \cdot 3^4 \cdot s_d^2} \frac{(a_1 + \sqrt{|d|})^{16} (a_1 - \sqrt{|d|})^{16}}{(a_2^2 + a_3^2)^4} \omega_d^{16} = \frac{3^4 A_d^2 (a_2^2 + a_3^2)^4}{2^{20} s_d^2} \omega_d^{16}.
\]
we deduce that

\[ B_d \left| d \right|^{12} \left( \frac{\omega_d}{\sqrt{3}} \right)^{12} = \frac{27(1 + \sqrt{3})^6 \omega_{-3}^{12} |d|^3}{256\pi^6 (a_1 + a_3\sqrt{3})^6} G_1(t_d)^{12} \left| 1 - \frac{\tau_d - \tau_{-3}}{\tau_d - \tau_{-3}} \right|^{12} \]

so that

\[ G_1(\tau_d)^{12} = \frac{B_d(\sqrt{3}(a_1 + a_2 - a_3) + \sqrt{|d|})^6}{27 \omega_{-3}^{12} |d|^3} \left( \frac{\omega_d}{\omega_{-3}} \right)^{12} \]

and

\[ G_1(\tau_d)^{12} G_2(\tau_d)^{12} = \frac{4 \omega_{-24}^{24} G_1(t_d)^{24}}{G_2(t_d)^{24}} \left( \frac{\sqrt{3}(a_1 + a_2 - a_3) - \sqrt{|d|}}{\sqrt{3}(a_1 + a_2 - a_3) + \sqrt{|d|}} \right)^6 \]

\[ = \frac{B_d^2}{2^{12} \cdot 3^6} \left( 3(a_1 + a_2 - a_3)^2 - |d| \right)^6 \omega_d^{24} \]

\[ = \frac{B_d^2}{26 \cdot 3^6} \left( a_1^2 + 3a_2^2 + 3a_3^2 + 3a_1a_2 - 3a_2a_3 - 3a_1a_3 \right)^6 \omega_d^{24}. \]

With Lemma [26] these two identities reduce to (25) and (26), respectively. This completes the proof. □

**Proof of Theorem** [2] The values of \( s(\tau) \) and \( t(\tau) \) at CM-points were computed in [13]. They are the rational numbers \( M/N \) from the two tables in Theorem [2] The optimal embeddings corresponding to the CM-points inside the fundamental domain are given in the two tables below.

| \( d \) | \( \phi(\sqrt{d}) \) | \( d \) | \( \phi(\sqrt{d}) \) |
|---|---|---|---|
| -52 | \( 8I + 2IJ \) | -120 | \( 12I - 2J + 2IJ \) |
| -88 | \( 10I + 2IJ \) | -43 | \( 7I - J + IJ \) |
| -132 | \( 12I + 2IJ \) | -232 | \( 16I - 2J + 2IJ \) |
| -312 | \( 18I + 2IJ \) | -163 | \( 13I - J + IJ \) |
| -148 | \( 14I + 4IJ \) | | |
| -708 | \( 30I + 8IJ \) | | |

Here the left columns of the two tables are for discriminants \( d \) with \( s(\tau_d) > 0 \) and \( t(\tau_d) > 0 \), respectively. Combining informations from Lemma [25] Proposition [27] and the above two tables, we obtain the identities in Theorem [2] □
6. FURTHER EXAMPLES

Observe that for each discriminant \( d \) appearing in Theorem 2 there is only one CM-point of discriminant \( d \) on the Shimura curve \( X_0(1)/\mathcal{O}_5 \). In such cases, Schofer’s formula readily tells us the absolute value of a Borcherds form at the unique CM-point of discriminant \( d \). However, in general, we can only read from Schofer’s formula the products of values of Borcherds forms at CM-points. In this section, we introduce a technique to separate the value at a CM-point from those at the other CM-points of the same discriminant using Hecke operators. This technique relies on the method developed in [36] for computing Hecke operators. Here we will work out the case \( d = -276 \). In principle, the method works at least for any imaginary quadratic number field whose ideal class group, after quotient by the prime ideals lying above 2 and 3, is an elementary 2-group.

Let \( E = \mathbb{Q}(\sqrt{-276}) \) and \( R \) be the ring of integers in \( E \). There are two CM-points of discriminant \( d = -276 \) on \( X_0(1)/\mathcal{O}_6 \), represented by the two points

\[
\tau_1 = \frac{-69}{9 + 2\sqrt{3}}, \quad \tau_2 = \frac{-3\sqrt{3} + \sqrt{-69}}{12 + 4\sqrt{3}}
\]

in the fundamental domain. The corresponding optimal embeddings \( \phi_1 \) and \( \phi_2 \) are

\[
\lambda_1 = \phi_1(\sqrt{-276}) = 18I + 4IJ, \quad \lambda_2 = \phi_2(\sqrt{-276}) = 24I - 6J + 8IJ,
\]

respectively. According to the table at the end of Section 5 of [34], the values of the Hauptmodul \( s(\tau) \) at these two points are \((166139596 \pm 95538528\sqrt{3})/1771561\). (The values can also be determined using Borcherds forms and Schofer’s formula.) From Lemma 26 we deduce that

\[
s(\tau_1) = \frac{166139596 - 95538528\sqrt{3}}{1771561}, \quad s(\tau_2) = \frac{166139596 + 95538528\sqrt{3}}{1771561}.
\]

Call these two numbers \( s_1 \) and \( s_2 \), respectively. Let \( p_2 \) and \( p_3 \) be the prime ideals of \( R \) lying above 2 and 3, respectively, and let \( p_5 \) be any prime above 5. Then the ideal class group of \( R \) is isomorphic to \((\mathbb{Z}/2\mathbb{Z}) \times (\mathbb{Z}/4\mathbb{Z})\) generated by the element \( p_2 \) of order 2 and the element \( p_5 \) of order 4. Moreover, the product \( p_2 p_3 p_5^2 \) is a principal ideal. It follows that the ideal class group, after quotient by the subgroup generated by \( p_2 \) and \( p_3 \), is cyclic of order 2 and generated by \( p_5 \). In terms of CM-points on \( X_0(1)/\mathcal{O}_6 \), this means that there should exist an element \( \alpha \) of norm 5, 10, 15, or 30 in \( \mathcal{O} \) such that \( \iota(\alpha)\tau_1 = \tau_2 \). (Here we retain the notations \( \mathcal{O}, \iota, \) and etc. used in Section 2.) Indeed, such an element is

\[
\alpha = 3 - 2I - JI.
\]

(Another element is \( \alpha' = (3 - 9I + J - 3IJ)/2 \).) In other words, we have \( \lambda_2 = \alpha \lambda_1 \alpha^{-1} \).

Now let \( F(\tau) = \psi_{F_1}(\tau) \) be the modular form of weight 8 defined in Proposition 14 and set

\[
\tilde{F}(\tau) := F|_{s(\tau)(\alpha)} = \frac{10^4}{((2 + \sqrt{3})\tau - 3)^8} F\left(\frac{3\tau + 2 - \sqrt{3}}{-2 - \sqrt{3}\tau + 3}\right).
\]

In general, we have

\[
\frac{10^4}{((2 + \sqrt{3})\tau - 3)^8} = \left(\frac{\text{Im} \iota(\alpha)\tau}{\text{Im} \tau}\right)^4.
\]

Thus,

\[
|F(\tau_2)| = \left(\frac{\text{Im} \tau_1}{\text{Im} \tau_2}\right)^4 |\tilde{F}(\tau_1)|.
\]

(28)
On the other hand, Schofer’s formula yields
\[ |F(\tau_1)F(\tau_2)| (\text{Im} \tau_1)^4 (\text{Im} \tau_2)^4 = 2^8 \cdot 3^4 \cdot 11^2 \left( \frac{|d|^2}{64 \pi^4 \omega_d^8} \right)^2. \]

Substituting (28) into this, we obtain
\[ (29) \quad |F(\tau_1)(\text{Im} \tau_1)^4|^2 \left| \frac{\tilde{F}(\tau_1)}{F(\tau_1)} \right| = 2^8 \cdot 3^4 \cdot 11^2 \left( \frac{|d|^2}{64 \pi^4 \omega_d^8} \right)^2. \]

The main task remaining is to determine the value of \( \tilde{F}(\tau_1)/F(\tau_1) \).

Let \( \Gamma \) be the discrete subgroup of \( \text{PSL}(2, \mathbb{R}) \) such that \( \mathcal{X}_5^s(1)/4 = \Gamma \setminus \mathbb{H}^+ \), i.e., \( \Gamma := \{ \epsilon(\gamma)/(\det \gamma)^{1/2} : \gamma \in \mathcal{N}_5^s(\mathcal{O}) \} \). Let \( \gamma_j, j = 1, \ldots, 5 \), be elements in \( \Gamma \iota(\alpha) \Gamma \) such that \( \gamma_0 = \iota(\alpha) \) and \( \gamma_j, j = 1, \ldots, 5 \), form a complete set of coset representatives of \( \Gamma \setminus \Gamma \iota(\alpha) \Gamma \). In Section 4 of \([35]\), by using results from \([36]\), we find that \( (\det \gamma_0)^{1/2} \). Substituting (30) into (29), we obtain
\[ \frac{5}{\prod_{j=0}^{5} \left( y - \frac{F(s)^{\gamma_j}}{F} \right)} = y^6 + \frac{114}{125} y^5 - \frac{6333}{78125} y^4 + \frac{4}{511} (8640000 s - 5177953) y^3 \\
+ \frac{3}{515} (8467200000 s + 1804020975) y^2 \\
+ \frac{726}{520} (93744000000 s - 3501556201) y \\
+ \frac{1}{576} (138240 s + 14641)^2. \]

Substituting \( s \) by \( s_1 = (166139596 - 95538528 \sqrt{3})/1771561 \), we deduce that \( \tilde{F}(\tau_1)/F(\tau_1) \) is a zero of
\[ (9150625 y^2 + 40464094 y - 20903960 \sqrt{3}) y + 82650625 - 47425000 \sqrt{3}) g(y), \]

where \( g(y) \in \mathbb{Q}(\sqrt{3})[y] \) is an irreducible polynomial of degree 4 over \( \mathbb{Q}(\sqrt{3}) \). In fact, we can show that it is a zero of the factor of degree 2 shown above. Hence, we have
\[ (30) \quad \left| \frac{\tilde{F}(\tau_1)}{F(\tau_1)} \right| = \left( \frac{82650625 - 47425000 \sqrt{3}}{9150625} \right)^{1/2} = \left( \frac{14 - 5 \sqrt{3}}{11} \right)^2. \]

(It is possible to determine the precise value, not just the absolute value. The two zeros of the factor of degree 2 are \( \tilde{F}(\tau_1)/F(\tau_1) \) and the value of \( (F|_{\iota(\alpha')})/F \) at \( \tau_1 \), where \( \alpha' = (3 - 9 I + J - 3 I J)/2 \). It is easy to find the ratio of the two values and hence determine \( \tilde{F}(\tau_1)/F(\tau_1) \).) Substituting (30) into (29), we obtain
\[ |F(\tau_1)(\text{Im} \tau_1)^4| = 144(14 + 5 \sqrt{3}) \left( \frac{|d|^2}{64 \pi^4 \omega_d^8} \right)^2. \]

By Proposition [27] this implies that
\[ 2F_1 \left( \frac{1}{24}, \frac{5}{24}, \frac{3}{4}; \frac{3}{4}; s_1 \right)^8 = \frac{3(14 + 5 \sqrt{3})}{16} (9 + \sqrt{69}) (\omega_{-276}/\omega_{-4})^8 \]
and
\[ 3F_2 \left( \frac{1}{3}, \frac{1}{2}, \frac{3}{4}, \frac{3}{4}, \frac{5}{4}; s_1 \right)^4 = \left( \frac{3(16 + 23 \sqrt{3})}{11} \right)^4 \left( \frac{2 + 3 \sqrt{3}}{23} \right)^2 (2 + \sqrt{3}) \omega_{-276}^8. \]
