PARTIAL DEHN TWISTS OF FREE GROUPS RELATIVE TO LOCAL DEHN TWISTS - A DICHOTOMY

KAIDI YE

Abstract. A criterion for quadratic or higher growth of group automorphisms is established which are represented by graph-of-groups automorphisms with certain well specified properties.

As a consequence, it is derived (using results of a previous paper of the author) that every partial Dehn twist automorphism of \( F_n \) relative to local Dehn twist automorphisms is either an honest Dehn twist automorphism, or else has quadratic growth.

1. Introduction

Dehn twist are well known from surface homeomorphisms: Any set \( C \) of pairwise disjoint essential closed curves \( c_i \) on a surface \( S \), together with a set of twist exponents \( n_i \in \mathbb{Z} \), defines a homeomorphism \( h: S \to S \) through “twisting” \( S \) along each \( c_i \) precisely \( n_i \) times.

The set \( C \) defines canonically a dual graph-of-groups \( G \) with isomorphism \( \pi_1 G \cong \pi_1 S \), where the vertex groups of \( G \) are the fundamental groups of the components of \( S - C \) and the edge groups are isomorphic to \( \mathbb{Z} \). The automorphism \( h*: \pi_1 S \to \pi_1 S \) induced by the multi-Dehn-twist \( h \) can be described algebraically through a graph-of-groups isomorphism \( H: \mathcal{G} \to \mathcal{G} \).

This natural correspondence between geometric and algebraic data has given rise to a more general definition of a Dehn twist automorphism \( \varphi \) of a group \( G \), via a graph-of-groups \( \mathcal{G} \) equipped with an isomorphism \( \pi_1 \mathcal{G} \cong G \) and a graph-of-groups isomorphism \( H: \mathcal{G} \to \mathcal{G} \), which satisfy extra conditions that mimic the above described surface situation, so that one gets \( H* = \varphi \) (up to inner automorphisms).

A special case, which is useful in many circumstances, is given by requiring that \( H \) acts trivially on the underlying graph \( \Gamma(\mathcal{G}) \) and on each of the vertex groups \( G_v \) of \( \mathcal{G} \), and that furthermore all edge groups of \( \mathcal{G} \) are trivial. In this case the automorphism \( H*: \pi_1 \mathcal{G} \to \pi_1 \mathcal{G} \) is determined by the family of correction terms \( \delta_e \in G_\tau(e) \) for any edge \( e \) of \( \mathcal{G} \), where \( \tau(e) \) denotes the terminal vertex of \( e \).

In the paper [10] the more general case of a partial Dehn twist \( H: \mathcal{G} \to \mathcal{G} \) relative to a subset \( \mathcal{V} \) of vertices of \( \mathcal{G} \) has been investigated, which differs
from the above described situation in that for any $v \in V$ the induced vertex group automorphism $H_v : G_v \to G_v$ may not be the identity.

If for each $v \in V$ the map $H_v : G_v \to G_v$ is itself a Dehn twist automorphism, then $H : G \to G$ is called a partial Dehn twist relative to a family of local Dehn twists. It is shown in [10] that in this case $H$ can be blown-up to a refined graph-of-groups isomorphism which is a Dehn twist that incorporates both, $H$ and the family of all $H_v$, provided that the following criterion is satisfied:

**Criterion:** For every edge $e$ of $H$ with endpoint $v \in V$ the correction term $\delta_e$ is $H_v$-zero.

Here for any graph-of-groups automorphism $H : G \to G$, the associated path group $\Pi(G)$, and any vertex $v$ of $G$ an element $g \in \pi_1(G, v) \subset \Pi(G)$ is $H$-zero if and only if there exists an element $h \in \Pi(G)$ such that $h^{-1}gh = 1$ has $G$-length 0.

The main result of this paper is to show that this sufficient criterion is also necessary. In fact, we show:

**Theorem 1.1.** Let $H : G \to G$ be a partial Dehn twist relative to a subset $V$ of vertices of $G$. Assume for some $v \in V$ that the vertex group $G_v$ is free, and that $H_v : G_v \to G_v$ is a Dehn twist automorphisms.

If there is an edge $e$ of $G$ with correction term $\delta_e \in G_v$ that is not $H_v$-zero, then the automorphism $H_* : \pi_1 G \to \pi_1 G$ has at least quadratic growth.

Since Dehn twist automorphisms are known to have linear growth, this shows that $H_*$ is not conjugate to any Dehn twist automorphism. In particular, $H$ can indeed not be blown up via the local Dehn twists $H_v$ to obtain a global Dehn twist of $\pi_1 G$.

By combining this theorem with the main result of [10], we obtain:

**Corollary 1.2.** Let $\tilde{\varphi} \in \text{Out}(F_n)$ be represented by a partial Dehn twist relative to a family of local Dehn twists.

Then either $\tilde{\varphi}$ is itself a Dehn twist automorphism, or else $\tilde{\varphi}$ has at least quadratic growth.

The proof of this corollary is algorithmic, i.e. it can be effectively decided which alternative of the stated dichotomy holds. This is a crucial ingredient in the author’s work [11], where an algorithm is given that decides whether a polynomial growth automorphism of a free group $F_n$ is, up to passing to a power, induced by a surface homeomorphism. It is also the starting point of a more detailed analysis of the growth of conjugacy classes for polynomially growing automorphisms of $F_n$, see [11].

**Acknowledgements.**

This paper is part of my PhD thesis, and I would like to thank sincerely my advisors, Arnaud Hilion and Martin Lustig, for their advice and encouragement.
2. Graphs-of-groups and their isomorphisms

The purpose of this and the following section is to briefly recall some basic knowledge and to establish some preliminary lemmas about graph-of-groups, Dehn twists on graph-of-groups, efficient Dehn twist as well as the notion of $H$-conjugation, which is introduced in [10].

2.1. Basics on graphs-of-groups.

Most of our notations are taken from [3]; we refer the readers to [8], [7] and [1] for more detailed informations and discussions.

Throughout this paper, we refer to a graph as a finite, non-empty, connected graph in the sense of Serre (cf. [8]).

For a graph $\Gamma$, we denote by $V(\Gamma)$, $E(\Gamma)$ its vertex set and edge set respectively. For an edge $e \in E(\Gamma)$, we denote by $\tau(e)$ its terminal vertex and $\tau(e)$ its initial vertex. The inverse of an edge $e$ is denoted by $e^\tau$.

Notice in particular that our graph $\Gamma$ is non-oriented while one can always choose an orientation $E^+(\Gamma) \subset E(\Gamma)$, which satisfies that $E^+(\Gamma) \cup E^+(\Gamma) = E(\Gamma)$ and $E^+(\Gamma) \cap E^+(\Gamma) = \emptyset$, where $E^+(\Gamma) = \{\overline{e} \mid e \in E^+(\Gamma)\}$.

Definition 2.1. A graph-of-groups $\mathcal{G}$ is defined by

$$\mathcal{G} = (\Gamma, (G_v)_{v \in V(\Gamma)}, (G_e)_{e \in E(\Gamma)}, (f_e)_{e \in E(\Gamma)})$$

where:

1. $\Gamma$ is a graph, called the underlying graph;
2. each $G_v$ is a group, called the vertex group of $v$;
3. each $G_e$ is a group, called the edge group of $e$, and we require $G_e = G_{\tau(e)}$ for every $e \in E(\Gamma)$;
4. for each $e \in E(\Gamma)$, the map $f_e : G_e \to G_{\tau(e)}$ is an injective edge homomorphism.

Unless otherwise stated, in this paper we will always assume that all vertex and all edge groups of any graph-of-groups $\mathcal{G}$ are finitely generated.

Given a graph-of-groups $\mathcal{G}$, we usually denote by $\Gamma(\mathcal{G})$ the graph underlying it. The vertex set of $\Gamma(\mathcal{G})$ is denoted by $V(\mathcal{G})$ while the edge set is denoted by $E(\mathcal{G})$.

Definition 2.2. The word group $W(\mathcal{G})$ of a graph-of-groups $\mathcal{G}$ is the free product of vertex groups and the free group generated by stable letters $(t_e)_{e \in E(\Gamma)}$, i.e. $W(\mathcal{G}) = \ast_{v \in V(\Gamma)} (G_v) \ast F(\{t_e ; e \in E(\Gamma)\})$.

The path group (sometimes also called Bass group) of $\mathcal{G}$ is defined by $\Pi(\mathcal{G}) = W(\mathcal{G})/R$, where $R$ is the normal subgroup subjects to the following relations:

- $t_e = t_e^{\tau(e)}$, for every $e \in E(\Gamma)$;
- $f_e(g) = t_e f_e(g) t_e^{-1}$, for every $e \in E(\Gamma)$ and every $g \in G_e$.

Remark 2.3. A word $w \in W(\mathcal{G})$ can always be written in the form $w = r_0 t_1 r_1 \ldots r_{q-1} t_q r_q$ $(q \geq 0)$, where each $t_i \in F(\{t_e ; e \in E(\Gamma)\})$ stands for the stable letter of the edge $e_i$ and each $r_i \in \ast_{v \in V(\Gamma)} (G_v)$.
The sequence \((t_1, t_2, ..., t_q)\) is called the path type of \(w\), the number \(q\) is called the path length of \(w\). In this case, we say that \(e_1 e_2 ... e_q\) is the path underlying \(w\). Two path types \((t_1, t_2, ..., t_q)\) and \((t'_1, t'_2, ..., t'_s)\) are said to be same if and only if \(q = s\) and \(t_i = t'_i\) for each \(1 \leq i \leq q\).

**Definition 2.4.** Let \(w \in W(G)\) be a word of the form \(w = r_0 t_1 r_1 ... r_{q-1} t_q r_q\). The word \(w\) is said to be connected if \(r_0 \in G_\tau(\pi_1)\), \(r_q \in G_\tau(\pi_q)\), and \(\tau(e_i) = \tau(\pi_{i+1}), r_i \in G_\tau(\pi_i)\), for \(i = 1, 2, ..., q - 1\).

Moreover, if \(w\) is connected and \(\tau(e_q) = \tau(\pi_1)\), we say that \(w\) is a closed connected word issued at the vertex \(\tau(e_q)\).

**Definition 2.5.** Let \(w = r_0 t_1 r_1 ... r_{q-1} t_q r_q \in W(G)\), \(w\) is said to be reduced if it satisfies:

\[\begin{align*}
\Diamond & \text{ if } q = 0, \text{ then } w = r_0 \text{ isn’t equal to the unit element}; \\
\Diamond & \text{ if } q > 0, \text{ then whenever } t_i = t_{i+1}^{-1} \text{ for some } 1 \leq i \leq q - 1 \text{ we have } r_i \notin f_{e_i}(G_{e_i}).
\end{align*}\]

Moreover the word \(w\) is said to be cyclically reduced if it is reduced and if \(q > 0\) and \(t_1 = t_q^{-1}\), then \(r_q r_0 \notin f_{e_q}(G_{e_q})\).

We recall the following facts.

**Proposition 2.6.** For any graph-of-groups \(G\), the following holds:

1. Every non-trivial element of \(\Pi(G)\) can be represented as a reduced word.
2. Every reduced word is a non-trivial element in \(\Pi(G)\).
3. If \(w_1, w_2 \in W(G)\) are two reduced words representing the same element in \(\Pi(G)\), then \(w_1\) and \(w_2\) are of the same path type. In particular, \(w_2\) is reduced if and only if \(w_1\) is connected.

**Definition 2.7.** (fundamental groups)

1. Fundamental groups based at \(v_0\)
   
   For any \(v_0 \in V(\Gamma)\), the fundamental group based at \(v_0\), denoted by \(\pi_1(G, v_0)\), consists of the elements in \(\Pi(G)\) that are closed connected words issued at \(v_0\).

   For a vertex \(w_0 \in V(\Gamma)\) different from \(v_0\), we have \(\pi_1(G, v_0) \cong \pi_1(G, w_0)\). In fact, let \(W \in \Pi(G)\) be a connected word with underlying path from \(v_0\) to \(w_0\). The restriction of \(ad_W : \Pi(G) \to \Pi(G)\) to \(\pi_1(G, w_0)\) induces an isomorphism from \(\pi_1(G, w_0)\) to \(\pi_1(G, v_0)\). Sometimes we write \(\pi_1(G)\) when the choice of basepoint doesn’t make a difference.

2. Fundamental groups at a maximal tree \(T_0\)

   The fundamental group at \(T_0\), denoted by \(\pi_1(G, T_0)\), is generated by the groups \(G_v\), for all \(v \in V(\Gamma)\), and the elements \(t_e\), for all \(e \in E(\Gamma)\), subjects to the relations:

   \[\begin{align*}
   \Diamond & t_e^{-1} = t_\pi, t_e f_e(g) t_e^{-1} = f_e(g), \text{ for } e \in E(\Gamma), g \in G_e; \\
   \Diamond & t_e = 1, \text{ for } e \in E(T_0).
   \end{align*}\]
By definition we have immediately
\[ \pi_1(\mathcal{G}, T_0) = \Pi(\mathcal{G})/ \Leftrightarrow t_e = 1, e \in E(T_0) \Rightarrow . \]

It’s shown in the book of Serre [S] that the above two definitions of fundamental groups are equivalent.

**Theorem 2.8** (Serre). For a graph-of-groups \( \mathcal{G} \), let \( v_0 \) be a vertex and \( T_0 \) a maximal tree. Then \( \pi_1(\mathcal{G}, v_0) \cong \pi_1(\mathcal{G}, T_0) \).

It follows immediately that, for a graph-of-groups \( \mathcal{G} \) with trivial edge groups, the product \( *(G_v)_{v \in V(\mathcal{G})} \) is free and forms a free factor of \( \pi_1(\mathcal{G}) \), moreover the disjoint union of basis of each vertex group \( \bigcup_{v \in V(\mathcal{G})} \mathcal{B}_v \) is a subset of the basis of \( \pi_1(\mathcal{G}) \).

**Definition 2.9.** [Graph-of-groups Isomorphisms]
Let \( \mathcal{G}_1, \mathcal{G}_2 \) be two graphs of groups. Denote \( \Gamma_1 = \Gamma(\mathcal{G}_1) \) and \( \Gamma_2 = \Gamma(\mathcal{G}_2) \). An isomorphism \( H : \mathcal{G}_1 \rightarrow \mathcal{G}_2 \) is a tuple of the form
\[ H = (H_\Gamma, (H_v)_{v \in V(\Gamma_1)}, (H_e)_{e \in E(\Gamma_1)}, (\delta(e))_{e \in E(\Gamma_1)}) \]
where
1. \( H_\Gamma : \Gamma_1 \rightarrow \Gamma_2 \) is a graph isomorphism;
2. \( H_v : G_v \rightarrow G_{H_\Gamma(v)} \) is a group isomorphism, for any \( v \in V(\Gamma_1) \);
3. \( H_e = H_\tau : G_e \rightarrow G_{H_\Gamma(e)} \) is a group isomorphism, for any \( e \in E(\Gamma_1) \);
4. for every \( e \in E(\Gamma_1) \), the correction term \( \delta(e) \in G_{\tau(H_\Gamma(e))} \) is an element such that
\[ H_\tau(e)f_e = ad_{\delta(e)}f_{H_\Gamma(e)}H_e. \]

**Remark 2.10.** A graph-of-groups isomorphism \( H : \mathcal{G}_1 \rightarrow \mathcal{G}_2 \) induces an isomorphism \( H_* : \Pi(\mathcal{G}_1) \rightarrow \Pi(\mathcal{G}_2) \) defined on the generators by:
\[
H_*(g) = H_v(g), \text{ for } g \in G_v, v \in V(\Gamma_1);
H_*(t_e) = \delta(\tau) t_{H_\Gamma(e)} \delta(e)^{-1}, \text{ for } e \in E(\Gamma_1).
\]
It’s easy to verify by computation that \( H_* \) preserves the relations \( t_et_\tau = 1 \) for any \( e \in E(\mathcal{G}) \) and \( f_\tau(g) = t_e f_e(g) t_e^{-1} \), for any \( e \in E(\mathcal{G}) \) and \( g \in G_e \).

Furthermore, the restriction of \( H_* \) to \( \pi_1(\mathcal{G}_1, v) \), where \( v \in V(\Gamma_1) \), is also an isomorphism, denoted by \( H_*v : \pi_1(\mathcal{G}_1, v) \rightarrow \pi_1(\mathcal{G}_2, H_\Gamma(v)) \).

**Remark 2.11.** As in [3], we define the outer isomorphism induced by a group isomorphism \( f : G_1 \rightarrow G_2 \) as the equivalence class
\[ \hat{f} = \{ ad_g f : G_1 \rightarrow G_2 \mid g \in G_2 \}. \]
Hence \( H_*v \) induces an outer isomorphism \( \hat{H}_*v : \pi_1(\mathcal{G}_1, v) \rightarrow \pi_1(\mathcal{G}, H_\Gamma(v)) \).

Observe that when choosing a different vertex \( v_1 \) as basepoint, we may choose a word \( W \in \Pi(\mathcal{G}_1) \) with underlying path from \( v_1 \) to \( v \) to obtain the
following commutative diagram:

\[
\begin{array}{ccc}
\pi_1(G_1, v) & \xrightarrow{H \ast v} & \pi_1(G_2, H \Gamma(v)) \\
\downarrow{ad_w} & & \downarrow{ad_{H \ast (w)}} \\
\pi_1(G_1, v_1) & \xrightarrow{H \ast v_1} & \pi_1(G_2, H \Gamma(v_1))
\end{array}
\]

By Lemma 2.2 and Lemma 3.10 in [3], \( \hat{H} \ast v \) determines an outer isomorphism \( \hat{H} \ast v_1 : \pi_1(G_1, v_1) \to \pi_1(G_2, H \Gamma(v_1)) \).

In this sense, we observe that \( H : G_1 \to G_2 \) induces an outer isomorphism \( \hat{H} : \pi_1(G_1) \to \pi_1(G_2) \) which doesn’t depend on the choice of basepoint.

2.2. H-conjugation.

We recall in this subsection some basic definitions and properties about the notion of H-conjugation. Contrary to the previous subsection, which only contained standard definitions and notation, the content of this subsection has been defined in [10] and to our knowledge didn’t exist previously.

Definition 2.12. For a graph-of-groups automorphism \( H : G \to G \) two reduced words \( w_1, w_2 \in \Pi(G) \) are said to be H-conjugate to each other if there exists a reduced word \( w \in \Pi(G) \) such that \( w_1 = w H \ast (w)^{-1} \).

It’s easy to show that H-conjugation is a well-defined equivalence relation on \( \Pi(G) \).

Denote by \( [w]_H \) the set which consists of all elements in \( \Pi(G) \) that are H-conjugate to \( w \). We call \( [w]_H \) the H-conjugacy class of \( w \).

Recall that the path length of a word \( w \in \Pi(G) \) equals to the number of edges the path underlying \( w \) crosses. We denote the path length of \( w \) by \( ||w||_G \).

Definition 2.13. A reduced word \( w \in \Pi(G) \) is said to be H-minimal if it has the shortest path length among its H-conjugates. More specifically, if \( w \) is H-minimal, then for every \( w_0 \in \Pi(G) \), \( ||w_0 w H \ast (w_0)^{-1}||_G \geq ||w||_G \).

Since \( ||w||_G \) is a natural number, one has that every reduced word \( w \in \Pi(G) \) has a H-conjugate which is H-minimal.

Therefore there exists a well defined H-length:

\[
||w||_{G, H} = \min\{||gw H \ast (g)^{-1}||_G \mid g \in \Pi(G)\}.
\]

Moreover, \( ||w||_{G, H} = ||w||_G \) if and only if \( w \) is H-reduced.

Definition 2.14. A reduced word \( w \in \Pi(G) \) is called H-zero if and only if its H-length equals to zero, i.e. \( ||w||_{G, H} = 0 \).

It also can be shown that \( w \in \Pi(G) \) is H-minimal if and only if it is H-reduced, as defined below:

Definition 2.15. Let \( w \in \Pi(G) \) be a reduced word in the form of \( w = r_0 t_1 r_1 ... r_q t_q r_q, \) \( w \) is said to be H-reduced if its cannot be shortened by the elementary operation \( w \mapsto w_1 = (r_0 t_1)^{-1} w H \ast (r_0 t_1), \) i.e. \( ||w||_G = ||w_1||_G. \)
Remark 2.16. If \( w' = r_0 t_1 ... r_{k-1} t_k r_k \in [w]_H \) is \( H \)-reduced, then
\[
\begin{align*}
  w'_1 &= (r_0 t_1)^{-1} w' H_s(r_0 t_1) \\
  &\vdots \\
  w'_i &= (r_{i-1} t_i)^{-1} w'_{i-1} H_s(r_{i-1} t_i) \\
  &\vdots \\
  w'_k &= (r_{k-1} t_k)^{-1} w'_{k-1} H_s(r_{k-1} t_k)
\end{align*}
\]
are also \( H \)-reduced.

Moreover, since \( H_s \) preserves the path lengths of reduced words, we also have
\[
H^* (w') = w' H^*(w'), \quad H^{-1} (w') = H^{-1}(w') w' w'^{-1}
\]
are \( H \)-reduced.

Hence
\[
\bigcup_{i=\pm \infty} \{ H_i^*(w'), H_i^*(w'_1), ..., H_i^*(w'_k) \}
\]
covers all path types of \( H \)-reduced words in \([w]_H\).

Lemma 2.17. Given a graph-of-groups isomorphism \( H : \mathcal{G} \to \mathcal{G} \) which acts trivially on the underlying graph \( \Gamma = \Gamma(\mathcal{G}) \). Choose an arbitrary vertex \( v_0 \in V(\Gamma) \) as basepoint. For every closed reduced word \( W \in \pi_1(\mathcal{G}, v_0) \), there exist a vertex \( v_1 \in V(\Gamma) \) and a reduced word \( \gamma \in \Pi(\mathcal{G}) \) which underlies a path from \( v_0 \) to \( v_1 \) such that \( \gamma^{-1} W H(\gamma) \in \pi_1(\mathcal{G}, v_1) \) is \( H \)-reduced.

Proof. In general, for every reduced word \( W \in \Pi(\mathcal{G}) \), there exists \( \gamma \in \Pi(\mathcal{G}) \) such that \( \gamma^{-1} W H(\gamma) \) is \( H \)-reduced. In the case where \( H \) acts trivially on the graph \( \Gamma \), the reduced words \( \gamma \) and \( H(\gamma) \) underly exactly the same edge path. Hence the word \( \gamma^{-1} W H(\gamma) \) is a closed word issued at the terminal vertex of \( \gamma \).

Moreover, it derives from Section 2.2 that we can find such an \( H \)-reduced word with path type that is a subsequence of the path type of \( W \) by applying the elementary operation defined in Definition 2.15. \( \square \)

3. Dehn twists

3.1. Classical Dehn twist.

Definition 3.1. [Classical Dehn twist] A Dehn twist \( D \) of a graph-of-groups \( \mathcal{G} \) is a graph-of-groups automorphism \( D : \mathcal{G} \to \mathcal{G} \) which satisfies (where \( \Gamma = \Gamma(\mathcal{G}) \) denotes as usually the underlying graph):

1. \( D_\Gamma = id_\Gamma \);
2. \( D_v = id_{G_v} \), for all \( v \in V(\Gamma) \);
3. \( D_e = id_{G_e} \), for all \( e \in E(\Gamma) \);
4. for each \( G_e \), there is an element \( \gamma_e \in Z(G_e) \) such that the correction term satisfies \( \delta(e) = f_e(\gamma_e) \), where \( Z(G_e) \) denotes the center of \( G_e \).

We denote a Dehn twist defined as above by \( D = D(\mathcal{G}, (\gamma_e)_{e \in E(\mathcal{G})}) \).
Definition 3.4. In general, a group automorphism \( \pi \) is a general and partial Dehn twist outer automorphism.

Remark 3.3. The induced automorphism \( D_\ast : \Pi(G) \to \Pi(G) \) is defined on generators as follows:

\[
D_\ast(g) = g, \quad \text{for } g \in G_v, \quad v \in V(\Gamma);
\]

\[
D_\ast(t_e) = t_ef_e(z_e), \quad \text{for every } e \in E(\Gamma).
\]

In particular, the induced automorphism on the fundamental group, \( D_{1v} : \pi_1(G, v) \to \pi_1(G, v) \) where \( v \in V(\Gamma) \), is called a Dehn Twist automorphism.

Definition 3.4. In general, a group automorphism \( \varphi : G \to G \) is said to be a Dehn twist automorphism if it is represented by a graph-of-groups Dehn twist. More precisely, there exists a graph-of-groups \( G \), a vertex \( v \) of \( \Gamma(G) \), a Dehn twist \( D : G' \to G \), and an isomorphism \( \theta : G \to \pi_1(G, v) \) such that

\[
\varphi = \theta^{-1} \circ D_{1v} \circ \theta.
\]

In this case the induced outer automorphism \( \hat{\varphi} : G \to G \) is called a Dehn twist outer automorphism.

Remark 3.5. The reader may notice the following subtlety in the above definitions:

Because of the role of the base point \( v \) in Definition 3.4, it may well occur that two automorphisms \( \varphi_1 \) and \( \varphi_2 \) of a group \( G \) define the same outer automorphism \( \hat{\varphi}_1 = \hat{\varphi}_2 \) which is a Dehn twist outer automorphism, but only \( \varphi_1 \) is a Dehn twist automorphism, while \( \varphi_2 \) isn’t.

Proposition 3.6 (Proposition 5.4 [3]). Suppose \( G \) is a graph-of-groups which satisfies that for every edge \( e \) there is an element \( r_e \in G_{r(e)} \) with

\[
f_e(G_e) \cap r_ef_e(G_e)r_e^{-1} = \{1\}.
\]

Then two Dehn twists \( D = (G, (\gamma_e)_{e \in E(G)}) \), \( D' = (G', (\gamma'_e)_{e \in E(G)}) \) determine the same outer automorphism of \( \pi_1(G) \) if and only if \( z_e = z'_e \) for all \( e \in E(\Gamma) \).

This proposition shows that in many situations a Dehn twist on a given graph-of-groups is uniquely determined by its twistors. Thus sometimes we may define a Dehn twist by its twistors \( (z_e)_{e \in E(\Gamma)} \) (for each \( e \in E(\Gamma) \), \( z_e \in Z(G_e) \) and \( z_e = z_e^{-1} \)). In this case, we may conversely define:

\[
\gamma_e = \begin{cases} 
  z_e^{-1}, & e \in E^+(\Gamma) \\
  1, & e \in E^-(\Gamma). 
\end{cases}
\]

3.2 General and partial Dehn twists.

As discussed in [10], we can define a Dehn twist in a slightly more general context by replacing the last condition of Definition 3.1 by the following:

(4*) the correction term \( \delta(e) \in C(f_e(G_e)) \), where \( C(f_e(G_e)) \) denotes the centralizer of \( f_e(G_e) \) in \( G_{r(e)} \), for all \( e \in E(\Gamma) \).
We call a graph-of-groups automorphism which satisfies conditions (1) – (3) in Definition 3.1 and (4*) a general Dehn twist.

It’s shown in [10] that Dehn twists defined in either, the classical or the general version, are equivalent in the sense that: (i) every classical Dehn twist is a general Dehn twist; (ii) every general Dehn twist has a naturally corresponding classical Dehn twist which induces same outer automorphism.

On other hand, if \( G \) is a graph-of-groups with trival edge groups, and \( H : G \to G \) is an automorphism which acts trivially on the graph and vertex groups, then it follows immediately from the above definitions that \( H \) induces Dehn twist automorphisms, for any choice of the family of correction terms.

**Definition 3.7.** (a) A partial Dehn twist relative to a subset of vertices \( V = \{v_1, v_2, ..., v_m\} \) of \( G \) is a graph-of-groups automorphism \( H : G \to G \) such that

1. for every \( e \in E(G) \) with \( \tau(e) \in V \), the edge group \( G_e \) is trivial;
2. \( H \) satisfies all conditions of a general Dehn twist except at \( v_i \in V \).

That is to say, any of vertex group automorphism \( H_{v_i} \) with \( v_i \in V \) may not be trivial.

(b) More specifically, a partial Dehn twist relative to a family of local Dehn twists is a partial Dehn twist relative to a subset of vertices \( V \) of \( G \), and at any vertex \( v \in V \) the vertex group automorphism \( H_v : G_v \to G_v \) is a Dehn twist automorphism.

**Remark 3.8.** If some automorphism \( \varphi : G \to G \) is represented by a partial Dehn twist \( H : G \to G \) relative to a family of vertices \( v_i \in V \subset V(\Gamma(G)) \), where every vertex group automorphism \( H_{v_i} : G_{v_i} \to G_{v_i} \) induces an outer Dehn twist automorphism \( \tilde{H}_{v_i} \), then \( \varphi \) is a partial Dehn twist relative to a family of local Dehn twists.

This can be seen through replacing \( H \) by \( J \circ H \), where the graph-of-groups automorphism \( J : \tilde{G} \to \tilde{G} \) is the identity on all edge groups and on all vertex groups for vertices outside \( V \), and an inner automorphism on all \( G_{v_i} \) if \( v_i \in V \). Here the correction terms \( \delta_{v_i}^e \) for edges \( e \) with terminal vertex \( \tau(e) \notin V \) are trivial, while for edges \( e \) with \( \tau(e) \in V \) they are properly chosen to “undo” the inner automorphism \( J_{\tau(e)} \) on \( G_{\tau(e)} \), so that for any \( v \notin V \) the induced automorphism \( J_{sv} : \pi_1(\tilde{G}, v) \to \pi_1(\tilde{G}, v) \) is the identity map (and thus for any \( v \in V \) the automorphism \( J_{sv} \) is an inner automorphism). See Section 2.4 in [10] for more details.

3.3. **Efficient Dehn Twist.**

Unless otherwise stated, in this subsection we always assume \( D : G \to G \) is a Dehn twist defined in the classical meaning. We write \( D = D(G, (z_e)_{e \in E(G)}) \).

Two edges \( e_1 \) and \( e_2 \) with common terminal vertex \( v \) are called

1. positively bonded, if there exist \( n_1, n_2 \geq 1 \) such that \( f_{e_1}(z_{e_1}^{n_1}) \) and \( f_{e_2}(z_{e_2}^{n_2}) \) are conjugate in \( G_v \).
Proposition 3.10. For every vertex $\ast \ast$ negative bonded, if there exist $n_1 \geq 1$, $n_2 \leq 1$ such that $f_{e_1}(z_{e_1}^{n_1})$ and $f_{e_2}(z_{e_2}^{n_2})$ are conjugate in $G_v$.

For the rest of this subsection, we always assume for a graph-of-groups $G$ its fundamental group $\pi_1(G)$ is free and of finite rank $n \geq 2$. This implies, by definition of a classical Dehn twist, that any edge $e$ with non-trivial twistor $z_e$ has edge group $G_e \cong \mathbb{Z}$.

Definition 3.9 (Efficient Dehn twist $[3]$). A Dehn twist $D = D(G, (z_e)_{e \in E(G)})$ is said to be efficient if:

The graph-of-groups $G$ satisfies

1. $G$ is minimal: if $v = \tau(e)$ is a valence-one vertex, then the edge homomorphism $f_e : G_e \to G_v$ is not surjective.
2. There is no invisible vertex: there is no valence-two vertex $v = \tau(e_1) = \tau(e_2)$ ($e_1 \neq e_2$) such that both edge maps $f_{e_i} : G_{e_i} \to G_v$ ($i = 1, 2$) are surjective.
3. No proper power: if $r^p \in f_e(G_e)$ ($p \neq 0$) then $r \in f_e(G_e)$, for all $e \in E(\Gamma)$.

And together with the collection of twistors $(z_e)_{e \in E(\Gamma)}$, it also satisfies:

4. No unused edge: for every $e \in E(\Gamma)$, the twistor $z_e \neq 1$ (or equivalently $\gamma_e \neq \gamma_2$).
5. If $v = \tau(e_1) = \tau(e_2)$, then $e_1$ and $e_2$ are not positively bonded.

The following has been shown in $[3]$:

Proposition 3.10. For every vertex $v \in V(G)$ of an efficient Dehn twist $D : G \to G$ the group $G_v$ has rank

$$\text{rk}(G_v) \geq 2.$$  \hfill $\square$

Proposition 3.11. Let $D : G \to G$ be an efficient Dehn twist, and let $v \in V(G)$ be any vertex.

(a) A conjugacy class $[w]$ of $\pi_1(G, v)$ is fixed by $D_{sv}$ if and only if $w$ has $H$-length

$$\|w\|_{G,H} = 0.$$  

(b) An element $w \in \pi_1(G, v)$ is fixed by $D_{sv}$ if and only if $w \in G_v$.  \hfill $\square$

It’s shown in $[3]$ that every Dehn twist (classical or general) can be transformed algorithmically into an efficient Dehn twist, and furthermore, the latter is essentially unique:

Theorem 3.12. (1) For every Dehn twist $D = D(G, (z_e)_{e \in E(\Gamma)})$, there exists an efficient Dehn twist $D' = D(G', (z_e)_{e \in E(\Gamma')})$ and an isomorphism between fundamental groups $\rho : \pi_1(G, w) \to \pi_1(G', w')$, where $w \in V(\Gamma)$, $w' \in V(\Gamma')$ are properly chosen vertices, such that $D\rho = \rho D$.

(2) If $D'' = D(G'', (z_e)_{e \in E(\Gamma'')})$ is a second such efficient Dehn twist, with respect to a analogous fundamental group isomorphism $\rho_0$, then there exists
a graph-of-groups isomorphism $H : G' \to G''$ with $D'' = HD'H^{-1}$ and $\hat{\rho}_0 = \bar{H}\hat{\rho}$.

We now return to the issue of $H$-conjugation as recalled in the last section, but with the specification that the graph-of-groups isomorphism $H : G \to G$ is a Dehn twist $D$, and we are interested in $H$-reduced or rather $D$-reduced elements as discussed in Definition 2.14 and Remark 2.15.

**Remark 3.13** (D-reduced v.s. cyclically reduced).

(a) If the Dehn twist $D : G \to G$ is defined in the classical way, then an element $w \in \Pi(G)$ is $D$-reduced if and only if it’s cyclically reduced. In particular, if for some vertex $v_0 \in V(G)$ an element $w \in \pi_1(G,v_0) \subset \Pi(G)$ is $D$-reduced, then $w$ is $D$-zero if and only if it satisfies $\|w\|_G = 0$.

(b) However, for $w \in \Pi(G)$ which is not $D$-reduced (or equivalently, not cyclically reduced), its usual conjugates which are cyclically reduced and its $D$-conjugates which are $D$-reduced can be very different, in fact they may not even have the same path type.

This shows that even in case of an efficient Dehn twist $D$ for non-D-reduced word in $\Pi(G)$ being $D$-zero and having its cyclically reduced path length equals to zero are not equivalent.

In view of the existence result for efficient Dehn twist representatives from Theorem 3.12 (1) we will always, when an outer Dehn twist automorphism $\hat{\varphi} \in \text{Out}(F_n)$ is given without specification of a Dehn twist representative, assume that it is represented by an efficient Dehn twist $D : G \to G$. Similarly, a Dehn twist automorphism $\varphi \in \text{Out}(F_n)$ without specification of a Dehn twist representative is always assumed to be represented by an efficient Dehn twist $D : G \to G$.

Recall from Remark 3.5 that the last convention may appear slightly restrictive, in particular when it comes to a partial Dehn twist $D : G \to G$ relative to a subset $V$ of vertices $v_i$ of $G$ for which the induced vertex group automorphism $D_{v_i}$ is known to induce an outer Dehn twist automorphism $\hat{D}_{v_i}$. However, if follows from Remark 3.8 that this restriction is immaterial; this class of automorphisms is precisely the same as the one given in Definition 3.7 (b), i.e. the class of partial Dehn twists relative to a family of local Dehn twists.

In view of the uniqueness of $D$ affirmed by part (2) of Theorem 3.12, the following notion is well defined:

**Definition 3.14.** Let $\varphi \in \text{Aut}(F_n)$ be a Dehn twist automorphism. Then any element $w \in F_n$ is called $\varphi$-reduced (or $\varphi$-zero) if it is $D$-reduced (or $D$-zero) with respect to some efficient Dehn twist representative of $\varphi$.

### 4. Cancellation Results

#### 4.1. Growth type.

We first recall some standard notation and well know elementary facts:
Definition 4.1. Let $G$ be a finitely generated group, and let $X = \{x_1, x_2, \ldots, x_n\}$ denote its generating set. The length function with respect to the generating set $X$ is defined by setting for any $g \in G$:

$$|g|_X := \min\{k \geq 0 \mid g = x_{i_1}^{\epsilon_1} x_{i_2}^{\epsilon_2} \cdots x_{i_k}^{\epsilon_k}, i_j \in \{1, \ldots, n\}, \epsilon_j \in \{\pm 1\}\}.$$

The cyclic length of $g \in G$ is defined by

$$\|g\|_X := \min\{|hgh^{-1}|_X \mid h \in G\}.$$

Remark 4.2.

(1) For any $g \in G$ we have $|g|_X \geq 0$, and $|g|_X = 0$ holds if and only if $g = 1$.

(2) For any $g \in G$ the cyclic length $\|g\|_X$ is the minimum of all lengths of elements in the conjugacy class $[g]$. The elements $h \in G$ and $hgh^{-1}$ such that $|g|_X = |hgh^{-1}|_X$ may not be unique.

(3) If $G = F_n$ and $X$ is a basis, we also have $\|g\|_X = |gg|_X - |g|_X$.

Furthermore $\|g\|_X = |g|_X$ if and only if $g \in G$ is cyclically reduced.

(4) For any words $g, h \in F_n$ we always have $|gh| \leq |g| + |h|$.

Remark 4.3. For two sets of generators $X = \{x_1, x_2, \ldots, x_n\}$ and $X' = \{x'_1, x'_2, \ldots, x'_n\}$ of $G$, the length functions $| \cdot |_X$ and $| \cdot |_{X'}$ are equivalent up to a constant. To be more precise, there exists a constant $C > 0$ such that for all $g \in G$:

$$\frac{1}{C}|g|_X \leq |g|_{X'} \leq C|g|_X.$$

Definition 4.4. Let $\varphi \in Aut(G)$ be an automorphism and $X$ be any generating system of $G$. For any element $g \in G$ we introduce a function $Gr(\varphi, g)$ to trace the length of $g$ under the iteration of $\varphi$:

$$Gr(\varphi, g)(n) : \mathbb{N} \to \mathbb{N}$$

$$n \mapsto |\varphi^n(g)|_X$$

Similarly, for the cyclic length we have:

$$Gr_c(\varphi, g)(n) : \mathbb{N} \to \mathbb{N}$$

$$n \mapsto \|\varphi^n(g)\|_X$$

Notice that for $\varphi \in Aut(G)$, $g_1, g_2 \in [g]$, and $n \in \mathbb{N}$ one has:

$$Gr_c(\varphi, g_1)(n) = Gr_c(\varphi, g_2)(n)$$

Also, for $\hat{\varphi} \in Out(G)$ and $\varphi_1, \varphi_2 \in \hat{\varphi}$ we obtain

$$Gr_c(\varphi_1, g)(n) = Gr_c(\varphi_2, g)(n)$$

for all $g \in G$, $n \in \mathbb{N}$. Thus it makes sense to consider the cyclic length of the conjugacy class $[g]$ (or equivalently $g \in [g]$) under the iteration of the outer automorphism $\hat{\varphi} \in Out(G)$. 
Definition 4.5 (growth type). (a) We say that \( g ∈ G \) grows at most polynomially of degree \( d \) under iteration of \( ϕ ∈ Aut(G) \) if \( Gr(ϕ, g) \) is bounded above by a polynomial of degree \( d \). The conjugacy class \([g]\) grows at most polynomially of degree \( d \) under iteration of \( ϕ ∈ Out(G) \) (or equivalently, of \( ϕ ∈ ˆφ \)) if \( Gr(ϕ, [g]) \) (or \( Gr(ϕ, [g]) \)) is bounded above by a polynomial of degree \( d \).

The automorphism \( ϕ ∈ Aut(G) \) has at most polynomial growth of degree \( d \) if any \( g ∈ G \) grows at most polynomially of degree \( d \). Similarly, the outer automorphism \( ˆφ ∈ Aut(G) \) has at most polynomial growth of degree \( d \) if any \( [g] ∈ G \) grows at most polynomially of degree \( d \).

(b) Similarly we say that \( g ∈ G \) (or \([g]\)) grows at least polynomially of degree \( d \) under iteration of \( ϕ ∈ Aut(G) \) (or of \( ˆφ ∈ Out(G) \) respectively) if \( Gr(ϕ, g) \) (or \( Gr(ϕ, [g]) \)) is bounded below by a polynomial of degree \( d \) with positive leading coefficient.

The automorphism \( ϕ ∈ Aut(G) \) has at least polynomial growth of degree \( d \) if some \( g ∈ G \) grows at least polynomially of degree \( d \). Similarly, the outer automorphism \( ˆφ ∈ Aut(G) \) has at least polynomial growth of degree \( d \) if some \( [g] ∈ G \) grows at least polynomially of degree \( d \).

(c) If \( g \) (or \([g]\)) grows both at most and at least polynomially of degree \( d \), then we say that it grows polynomially of degree \( d \).

(d) An automorphism \( ϕ ∈ Aut(G) \) (or an outer automorphism \( ˆφ ∈ Out(G) \)) grows polynomially of degree \( d \) if every \( g ∈ G \) (or every \([g] ∈ G\)) grows at most polynomially of degree \( d \) and in particular there exists an element \( g_0 ∈ G \) (or a conjugacy class \([g] ∈ G\)) that grows polynomially of degree \( d \).

Remark 4.6. Because the length functions with respect to different generating systems are equivalent up to a constant, the definitions about growth types given in Definition 4.5 are independent of the chosen generating system of \( G \).

Definition 4.7. Let \((w_k)_{k=1}^{+∞}\) a family of elements in \( G \), we sometimes say that the sequence \( w_k \) grows at least polynomially of degree \( d \) if there exists constant \( C_1 > 0 \) such that \( C_1 k^d ≤ |w_k| \). Similarly, we say that \( w_k \) grows at most polynomially of degree \( d \) if there exists \( C_2 > 0 \) such that \( |w_k| ≤ C_2 k^d \) and that \( w_k \) grows polynomially of degree \( d \) if one can find \( C_1, C_2 > 0 \) such that \( C_1 k^d ≤ |w_k| ≤ C_2 k^d \).

4.2. Cancellation and iterated products.

Let \( F_n \) be a free group and denote by \( A \) a fixed basis of \( F_n \). As before, we denote the combinatorial length (with respect to \( A \)) of an element \( W \) by \( |W| = |W|_A \), and the cyclically reduced length of \( W \) by \( ||W|| = ||W||_A \).

Lemma 4.8. Let \( F_n \) be a free group, let \( V ⊂ F_n \) be a subgroup of rank \( n ≥ 2 \), and let \((w_i)_{i∈N}\) be any infinite family of elements \( w_i ∈ F_n \). Then for any basis \( A \) of \( F_n \) there exists an element \( v ∈ V \) and a constant \( C ≥ 0 \) such that for infinitely many indices \( i ∈ N \) the cancellation in the product...
\[ |w_ivw_i^{-1}|_A \text{ is bounded, i.e. one has:} \]
\[ |w_ivw_i^{-1}|_A \geq |w_i|_A + |v|_A + |w_i^{-1}|_A - C = 2|w_i|_A + |v|_A - C \]

**Proof.** Pick elements \( v_1 \) and \( v_2 \) in \( V \) which generate a subgroup of rank 2. Consider the products \( w_i v_1^m w_i^{-1} \), for increasing integers \( m \). We observe that one of the following must hold:

1. For some \( m \in \mathbb{N} \) the cancellation in \( w_i v_1^m w_i^{-1} \) is bounded uniformly with respect to all \( i \in \mathbb{N} \).
2. For any \( m \in \mathbb{N} \) there is an index \( j(m) \in \mathbb{N} \) such that \( w_j(m) \) has the suffix \( v_1^{-m} \).
3. For any \( m \in \mathbb{N} \) there is an index \( j'(m) \in \mathbb{N} \) such that \( w_j'(m) \) has the prefix \( v_1^{-m} \), or equivalently, \( w_j'(m) \) has the suffix \( v_1^m \).

In the case of alternative (1), the proof is completed. In case of (2), we replace the family of all \( w_i \) by the subfamily of all \( w_j \) with \( j = j(m) \) for any \( m \in \mathbb{N} \). It follows from the statement (2) that this subfamily is infinite. In case (3) we do the same, but with \( j = j'(m) \).

We now repeat the above trichotomy, with \( w_i \) replaced by \( w_j \), and with \( v_1 \) replaced by \( v_2 \). We observe that in this second trichotomy the alternatives (2) and (3) lead to elements \( w_j \) with suffix that is simultaneously an arbitrary large positive or negative power of \( v_1 \) and of \( v_2 \). But this is impossible, by our assumption that \( v_1 \) and \( v_2 \) generate a subgroup of rank 2. Thus alternative (1) must hold for the second trichotomy, which proves our claim. \( \square \)

### 4.3. Cancellation in long products.

**Definition 4.9.** We say \( U \) and \( V \) admit a common root if there exist an element \( R \in F_n \), \( R \neq 1 \), such that \( U = R^{m_1}, V = R^{m_2} \) for some suitable \( m_1, m_2 \in \mathbb{N} \). \( R \) is called a common root of \( U \) and \( V \).

We recall the following well known fact:

**Proposition 4.10 ([5]).** For any elements \( U, V \in F_n \), there is an algorithm which decides whether they admit a common root.

The following is well-known too:

**Lemma 4.11.** For two elements \( U, V \in F_n \) we have \( U^{n_1} \neq V^{n_2} \) for any \( n_1, n_2 \geq 1 \) if and only if \( U, V \) don’t admit a common root.

**Proof.** On one hand, if \( U, V \) admit a common root \( R \) such that \( U = R^{m_1}, V = R^{m_2} \) for some \( m_1, m_2 \geq 1 \), then we have \( U^{m_2} = V^{m_1} \).

On the other hand, if there exist \( n_1, n_2 \geq 1 \) such that \( U^{n_1} = V^{n_2} \), by comparing the suffixes and prefixes of \( U \) and \( V \), we can find a common root \( R \in F_n \). \( \square \)

**Lemma 4.12.** If \( U^{-1}, V \in F_n \) don’t admit a common root, then the cancellation of the products \( U^{n_1} V^{n_2} \), for any \( n_1, n_2 \in \mathbb{N} \), is uniformly bounded.
As consequence, there exists a constant and $K_0 = K(U^{-1}, V)$ such that for any $n_1, n_2 \in \mathbb{N}$, we have:

$$|U^{n_1}V^{n_2}| \geq n_1\|U\| + n_2\|V\| + K_0$$

**Proof.** If no constant $K_0$ as postulated exists, then by comparing the subfixes and prefixes of $U$ and $V$ we can find a common root $R \in F_n$ for $U^{-1}$ and $V$, which contradicts our hypothesis.

Therefore by definition we can find $B_1 \geq 0$ such that

$$|U^{n_1}| + |V^{n_2}| - |U^{n_1}V^{n_2}| \leq B_1.$$ 

Hence, by taking $K_0 = -B_0$ we have

$$|U^{n_1}V^{n_2}| \geq |U^{n_1}| + |V^{n_2}| + K_0 \geq n_1\|U\| + n_2\|V\| + K_0$$

for any $n_1, n_2 \geq 0$. \hfill \qed

**Remark 4.13.** Furthermore, for $U^{-1}, V \in F_n$ which don’t admit a common root, we have at the same time that the cancellation of the products $V^{n_2}U^{n_1}$, for any $n_1, n_2 \in \mathbb{N}$, is uniformly bounded by some constant $B_2 \geq 0$. Taking $K = -B_1 - B_2$, we have immediately

$$\|U^{n_1}V^{n_2}\| \geq n_1\|U\| + n_2\|V\| + K.$$ 

**Lemma 4.14.** Let $X, b, Y \in F_n$ be elements such that $X^{-m_1} \neq bY^{m_2}b^{-1}$, for any $m_1, m_2 \geq 1$. Then there exists a constant $K = K(X, b, Y)$ such that for any $n_1, n_2 \geq 0$ we have:

$$|X^{n_1}bY^{n_2}| \geq n_1\|X\| + n_2\|Y\| + K.$$ 

**Proof.** For any $n_1, n_2 \geq 0$, we may consider the word

$$X^{n_1}bY^{n_2} = X^{n_1}bY^{n_2}b^{-1}b = X^{n_1}(bYb^{-1})^{n_2}b.$$ 

Taking $U = X$, $V = bYb^{-1}$, we know from Lemma 4.11 that $U^{-1}$, $V$ don’t admit a common root. Hence it follows from Lemma 4.12 that there exists $K_0 = K(U^{-1}, V)$ such that

$$|U^{n_1}V^{n_2}| \geq n_1\|U\| + n_2\|V\| + K_0.$$ 

Let $K = K_0 - |b|$, we have immediately the inequality

$$|X^{n_1}bY^{n_2}| = |U^{n_1}V^{n_2}b| \geq |U^{n_1}V^{n_2}| - |b| \geq n_1\|U\| + n_2\|V\| + K = n_1\|X\| + n_2\|Y\| + K.$$

\hfill \qed

**Remark 4.15.** Please notice that in the situation considered in Lemma 4.14 we may not have the following inequality:

$$\|X^{n_1}bY^{n_2}\| \geq n_1\|X\| + n_2\|Y\| + K$$

Counter-example: Consider $F_2 = \langle a, b \rangle$ and let $X = a^{-1}$, $Y = a$. 

Proposition 4.17. Let \( X, b, Y \in F_n \) be elements such that \( X^{-m_1} \neq bY^{m_2}b^{-1} \), for any \( m_1, m_2 \geq 1 \). Then there exist cyclically reduced conjugates \( \tilde{X}, \tilde{Y} \) of \( X, Y \) and \( n_0 \in \mathbb{N} \) such that for all \( n_1, n_2 \geq n_0 \), in the reduced product of \( X^{n_1}bY^{n_2} \) neither \( \tilde{X} \) nor \( \tilde{Y} \) is completely cancelled.

Proof. Consider the cyclically reduced conjugates \( \tilde{X} = w_1Xw_1^{-1}, \tilde{Y} = w_2Yw_2^{-1} \) for \( X, Y \), where \( w_1, w_2 \in F_n \). We may then write the word

\[
X^{n_1}bY^{n_2} = w_1^{-1}\tilde{X}^{n_1}w_1b\tilde{w}_2^{-1}\tilde{Y}^{n_2}\tilde{w}_2^{-1}.
\]

We derive from the uniformly bounded property that there exists \( n_0 \in \mathbb{N} \) such that when \( n_1, n_2 \geq n_0 \), in the reduced product of \( X^{n_1}bY^{n_2} = w_1^{-1}\tilde{X}^{n_1}w_1b\tilde{w}_2^{-1}\tilde{Y}^{n_2}\tilde{w}_2^{-1} \), neither \( \tilde{X} \) nor \( \tilde{Y} \) is completely cancelled.

More concretely, since we always have the inequality

\[
|X^{n_1}bY^{n_2}| \leq n_1||X|| + n_2||Y|| + 2|w_1| + 2|w_2| + |b|,
\]

it follows from Lemma 4.14 that the cancellation in the products \( X^{n_1}bY^{n_2} \) is uniformly bounded by \( B = 2|w_1| + 2|w_2| + |b| - K \), where \( K = K(X, b, Y) \) is the constant obtained in Lemma 4.14. Then we may choose \( n_0 \in \mathbb{N} \) that satisfies \( ||X^{n_0}|| = n_0||X||, ||Y^{n_0}|| = n_0||X|| \geq B \).

\[\square\]

4.4. Main cancellation result.

Let now \( \mathcal{F} \) be a set which consists of finitely many triplets \((X_i, b_j, X_k)\), where \( X_i, b_j, X_k \in F_n \) are elements which satisfy

1. \( ||X_i|| > 0 \) and \( ||X_k|| > 0 \), and
2. \( X_i^{-m_1} \neq b_jX_k^{-m_2}b_j^{-1} \), for any \( m_1 \geq 1, m_2 \geq 1 \).

We consider below words

\[
w = w(n_1, n_2, \ldots, n_q) = c_0y_1^{n_1}c_1y_2^{n_2}c_2 \cdots c_{q-1}y_q^{n_1}c_q \in F_n
\]

which have the property \((y_i, c_i, y_{i+1}) \in \mathcal{F} \), for \( 1 \leq i \leq q \).

We then derive the following proposition:

Proposition 4.17. There exist constants \( N_0 \geq 0 \) and \( K_0 \) such that for any \( w = w(n_1, n_2, \ldots, n_q) \in F_n \) as above and any \( n_i \geq N_0 \) (with \( 1 \leq i \leq q \)), we have

\[
|w| \geq \sum_{i=1}^{q} n_i||y_i|| + (q - 1)K_0.
\]

Proof. It follows directly from Lemma 4.14 and Remark 4.16 that for each triplet \((y_i, c_i, y_{i+1})\), \( 1 \leq i \leq q - 1 \), there exist constants \( K_i = K(y_i, c_i, y_{i+1}) \) and \( N_i \geq 0 \) such that:

\[
|y_i^{n_i}c_iy_{i+1}^{n_i+1}| \geq n_i||y_i|| + n_{i+1}||y_{i+1}|| + K_i
\]

Moreover, if \( n_i, n_{i+1} \geq N_i \) neither of the cyclically reduced conjugates \( \tilde{y}_i = w_iy_iw_i^{-1}, \tilde{y}_i + 1 = w_{i+1}y_{i+1}w_{i+1}^{-1} \) is completely cancelled in the reduced product

\[
y_i^{n_i}c_iy_{i+1}^{n_i+1} = w_i^{-1}y_i^{n_i}c_iw_{i+1}^{-1}y_{i+1}^{n_i+1}w_{i+1}.
\]
We now prove the proposition by induction.

(1) The case for \( q = 1 \) is trivial while the case for \( q = 2 \) is shown in Lemma 4.14.

(2) Suppose the inequality holds for \( q = s \). In other words: we can find constants \( N \geq N_{s-1} \) and \( K \) such that for \( n_i \geq N \)

\[
|c_0 y_1^{n_1} c_1 y_2^{n_2} c_2 \ldots c_{s-1} y_{s}^{n_s} c_s| \geq \sum_{i=1}^{s} n_i \|y_i\| + (s - 1)K
\]

and \( \tilde{y}_s^{n_s} \) is not completely cancelled in the reduced procedure.

In particular, given that in each inductive step the constants \( N \) and \( K' \) depends only on the triplets \((y_i, c_i, y_{i+1})\), for \( 1 \leq i \leq q - 1 \) one can in fact deduce the final cancellation bound \((q - 1)K_0\) based on just the family \( F \).

In other words, the cancellation bound \( K_0 \) doesn’t depend on the exponents \( n_i \)'s, once they are bigger than \( N_0 := N \).

\[\square\]

**Remark 4.18.** In addition if \((y_q, c_q c_0, y_1) \in F\), similarly to what is done in the last proof, we may apply the same technique to the triplet \((y_q, c_q c_0, y_1)\) and obtain the following estimate for cyclical length of \( w \) (again assuming \( n_i \geq N_0 \) for all exponents \( n_i \)):

\[
\|w\| \geq \sum_{i=1}^{q} n_i \|y_i\| + qK_0
\]

### 4.5. Cancellation bounds for \( \mathcal{T} \)-products.

Let \( \mathcal{T} \subset F_n \setminus \{1\} \) be a finite set. We say that a product

\[
W = W(w_i, y_i) = w_0 y_1 w_1 y_2 w_2 \ldots w_{q-1} y_q w_q
\]

is a \( \mathcal{T} \)-word of \( \mathcal{T} \)-length

\[
|W|_{\mathcal{T}} = q,
\]

if \( w_i \in F_n \) and \( y_i \in \mathcal{T} \) for all indices \( i \), and we say that the product \( W \) is \( \mathcal{T} \)-reduced if \( y_i^{-m} \neq w_i y_{i+1}^{m'} w_i^{-1} \) for any integers \( m, m' \geq 0 \).

For any \( \mathcal{T} \)-word \( W \) as in (4.1) and any multi-exponent

\[
[n] = (n_1, n_2, \ldots n_q) \in \mathbb{N}^q
\]

we denote by \( W^{[n]} \) the word

\[
W^{[n]} = w_0 y_1^{n_1} w_1 y_2^{n_2} w_2 \ldots w_{q-1} y_q^{n_q} w_q.
\]

For any \( n_0 \in \mathbb{Z} \) we write

\[
[n] \geq n_0
\]

if \( n_i \geq n_0 \) holds for all components \( n_i \) of \([n]\).
**Proposition 4.19.** (a) For any reduced \( T \)-word \( W \) as in (4.1) and any basis \( A \) of \( F_n \) there exist constants \( K = K(W) \geq 0 \) and \( n_0 \in \mathbb{Z} \) such that for any multi-exponent \( [n] \in \mathbb{N}^q \) as in (4.2), with \( [n] \geq n_0 \), the \( A \)-lengths satisfy

\[
|W[n]|_A \geq \sum_{k=1}^{q} n_k \|y_k\|_A - K
\]

(b) If all of the intermediate words \( w_i \) in \( W \) belong to a finite family \( W \), then the above constant \( K \) can be taken to be equal to \( (q - 1)K_0 \) for some constant \( K_0 \geq 0 \) which only depends on \( W \) and \( T \)-length, but not on the multi-exponent \( [n] \). Similarly, the constant \( n_0 \) can be chosen to depend only on \( W \).

**Proof.** For the given family \( W = W(w_i, y_i) \) we set

\[
\mathcal{F}(W) = \{(y, w, y') \mid w \in W, y, y' \in T, y^{-m} \neq wy^m w^{-1} \text{ if } m, n \geq 0\}
\]

Then our claim follows directly from Proposition 4.17. \( \Box \)

5. **Graph-of-groups with trivial edge groups: Growth bounds**

In this section we will suppress the base point \( v \) in the fundamental group \( \pi_1 G \) of a graph-of-groups \( G \) if it is immaterial, and write simply \( \pi_1 G \).

**Lemma 5.1.** Let \( G \) be a graph-of-groups with trivial edge groups. Let \( (W_i)_{i=1}^{\infty} \subset \pi_1(G) \) be a family of cyclically reduced words on \( G \), where \( W_i = v_0(i)t_1v_1(i)t_2...t_qv_q(i) \). If for some \( 1 \leq k \leq q \), the length of \( v_k(i) \) under some (hence any) finite generating system \( B_k \) of the vertex group \( G_{v_k} \), i.e. \( |v_k(i)|_{B_k} \), grows quadratically with respect to \( i \), then \( \|W_i\| \) grows at least quadratically with respect to \( i \).

**Proof.** As shown in Section 2.1 that the union of generating systems of each vertex group \( \bigcup_{v \in V(G)} B_v \) forms a subset of a generating system \( B \) of \( \pi_1(G) \), where each vertex group is a free factor.

We obtain:

\[
\|W_i\|_B \geq \sum_{k=1}^{q-1} |v_k(i)|_{B_k} + |v_q(i)v_0(i)|_{B_0}
\]

It follows immediately from the conditions that at least one of \( |v_k(i)|_{B_k} \) grows quadratically and that \( W_i \) is cyclically reduced that the cyclically reduced length of \( W_i \) grows at least quadratically.

\( \Box \)

Recall that a graph-of-groups \( G \) is called *minimal* if it doesn’t contain a proper subgraph \( G' \) such that the inclusion induces an isomorphism on the fundamental groups. For a finite graph-of-groups with trivial edge groups this amounts to requiring that any vertex of valence 1 has a non-trivial vertex group.
Lemma 5.2. Let $\mathcal{G}$ be a minimal graph-of-groups with trivial edge groups, Then for any edge $e$ with terminal vertex $v = \tau(e)$ that has non-trivial vertex group $G_v$ one can find a cyclically reduced word $w \in \pi_1(\mathcal{G})$ with underlying path that runs subsequently through the edge $e$ and directly after through $\overline{e}$.

Proof. Because $\mathcal{G}$ is a minimal graph-of-groups, each connected component of the graph $\Gamma'$ obtained from $\Gamma(\mathcal{G})$ by removing the edge $e$ must contain either a circuit $\omega$ or else a vertex $v'$ with non-trivial vertex group $G_{v'}$. Let $\gamma$ be a path in $\Gamma'$ which connects $\iota(e)$ either to the initial (= terminal) vertex of some such $\omega$, or else to $v'$. Let $v \in G_v \setminus \{1\}$ and $u \in G_{v'} \setminus \{1\}$ (in the second case only). Then $\gamma^{-1}_* ev\pm(v'\omega)$ (in the first case) or $\gamma^{-1}_* ev\pm(v'\omega)$ (in the second one) are the words we are looking for, where $\gamma_*$ and $\omega$ denote the sequence of stable letters $t_i$ defined by the edges $e_i$ of $\gamma$ and $\omega$ respectively. \hfill \Box

Proposition 5.3. Let $\mathcal{G}$ be a minimal graph-of-groups with trivial edge groups, and let $H : \mathcal{G} \to \mathcal{G}$ be a graph-of-groups automorphism which acts trivially on the underlying graph $\Gamma = \Gamma(\mathcal{G})$.

Let $v$ be a vertex of $\Gamma$, with vertex group automorphism $H_v : G_v \to G_v$. For some edge $e$ with terminal vertex $\tau(e) = v$ denote by $\delta_e \in G_v$ the correction term of $e$.

Assume that for some $g \in G_v$ there exist a constant $C > 0$ and a strictly increasing sequence of numbers $n_i \in \mathbb{Z}$ which satisfy:

$$|H_v^{(n_i)}(\delta_e^{-1})H_v^{g(n_i)}H_v^{(n_i)}(\delta_e^{-1})^{-1}| \geq Cn_i^2$$

Then the induced outer automorphism $\hat{H}$ of $\pi_1\mathcal{G}$ has at least quadratic growth.

Proof. If follows immediately from Lemma 5.2 that one can find cyclically reduced word $w \in \pi_1\mathcal{G}$ with underlying path that runs through the edge $e$ and subsequently through $\overline{e}$, and $w$ contains the word $t_igt_1$ as subword.

As a consequence the iteration of $H_* : \Pi(\mathcal{G}) \to \Pi(\mathcal{G})$ on $w$ will give words $H_v^{(k)}(w)$ that contain

$$t_igt_e^{-1}H_v^{(k)}(\delta_e^{-1})H_v^{g(n_i)}H_v^{(g(n_i))}(\delta_e^{-1})^{-1}t_1$$

as subword.

Hence it follows from the assumed inequality and from Lemma 5.1 that the subsequence $\|H_v^{g(n_i)}(w)\|$ grows at least quadratically. Therefore the conjugacy class of $w$ grows at least quadratically under the iteration of $H_*$, which implies that the induced outer automorphism $\hat{H}$ grow at least quadratically.

\hfill \Box

6. Dehn twists

This section is dedicated to translate our cancellation propositions into graph-of-groups language.

Through the whole section, we always assume that the free group $F_n$ is of rank $n \geq 2$.

We first prove the following Proposition.
Proposition 6.1. Let $F_n$ be a free group with rank $n \geq 2$, and let $D \in \text{Aut}(F_n)$ be a Dehn twist automorphism which is represented by an efficient Dehn twist. Then we have:

1. There exists a finite set of “twistors” $T = \{z_1, \ldots, z_r\} \subset F_n \setminus \{1\}$, such that for any element $w \in F_n$ there exists a (non-unique) “$T$-decomposition” of $w$ as product

\[
(6.1) \quad w = w_0 w_1 w_2 \ldots w_{q-1} w_q = w_0 y_1^0 w_1 y_2^0 w_2 \ldots w_{q-1} y_q^0 w_q
\]

with $w_i \in F_n$ and $y_i$ or $y_i^{-1}$ in $T$ such that

\[
D^n(w) = w_0 y_1^n w_1 y_2^n w_2 \ldots w_{q-1} y_q^n w_q,
\]

and $y_i^{-m} \neq w_i y_{i+1}^m w_i^{-1}$ for any integers $m, m' \geq 0$.

2. The rank of the subgroup of $F_n$ which consists of all elements fixed by $D$ satisfies:

\[
\text{rk}(\text{Fix}(D)) \geq 2
\]

Proof. By definition $D$ is represented by an efficient Dehn twist $D : G \to G$ on a graph-of-groups $G$ with fundamental group $\pi_1 G$ isomorphic to $F_n$. We pick a vertex $v_0$ of $G$ as base point and specify the above isomorphism to be $\theta : F_n \xrightarrow{\cong} \pi_1(G, v_0)$. The automorphism $D$ fixes the $\theta^{-1}$-image of the vertex group $G_{v_0}$ of $G$ elementwise, and since efficient Dehn twists have all vertex groups of rank $\geq 2$ (see Proposition 3.10), this proves claim (2) of the proposition.

In order to obtain claim (1), we chose a maximal tree $Y$ in the graph $\Gamma$ and identify in the usual fashion each vertex group $G_v$ canonically with a subgroup of $\pi_1(G, v_0)$ by connecting $v_0$ to $v$ through a simple path in $Y$. Similarly, for any edge $e$ the stable letter $t_e \in \Pi(G)$ gives rise to an element in $\pi_1(G, v_0)$ by connecting $v_0$ to the terminal vertices of $e$ through simple paths in $Y$ (which gives $1 \in \pi_1(G, v_0)$ if and only if $e$ belongs to $Y$).

The collection $T$ is then given by the twistors $z_e$ of the edges $e \in E^+(G)$ (for some orientation $E^+(G) \subset E(G)$, see subsection 2.1). For any $w \in F_n$ the collection of factors $w_i$ in the $T$-product decomposition (6.1) is obtained by writing $\theta(w)$ as a reduced word $v_0 t_1 v_1 t_2 v_2 \ldots v_{q-1} t_q v_q$ in $\pi_1(G, v_0)$ (see Proposition 2.6), and by applying $\theta^{-1}$ to $v_0$ or to any of the $t_i v_i$ for $i = 1, \ldots, q$. The equality $D^n(w) = w_0 y_1^n w_1 y_2^n w_2 \ldots w_{q-1} y_q^n w_q$ is an immediate consequence of the definition of a Dehn twist automorphism, see Remark 3.3. The inequalities $y_i^{-m} \neq w_i y_{i+1}^{m'} w_i^{-1}$, for any integers $m, m' \geq 0$, follow directly from the condition that the efficient Dehn twist $D$ does not have twistors that are positively bonded, see Definition 3.9 (5).

Remark 6.2. The representation of $w \in F_n$ as $T$-product as given in Proposition 6.1 is not unique. However, it follows from the proof that the sequence of twistors $y_i$ is well defined, and thus also the $T$-length $|w|_T$ of $w$. The intermediate words $w_i$ are well defined up to replacing them by $y_i^{p_i} w_i y_i^{q_i}$ for some $p, q \in \mathbb{Z}$. 

\[\square\]
Definition 6.3. A $\mathcal{T}$-product representative of $w \in F_n$ as in Proposition 6.1 is called cyclically $\mathcal{T}$-reduced if $y_q^{-m} \neq w_q w_0 y_q^{m'} w_0^{-1} w_q^{-1}$ for any integers $m, m' \geq 0$.

Definition-Remark 6.4.

(1) Let $\mathcal{D}$ and $\mathcal{T}$ be as in Proposition 6.1. Assume that $D : \mathcal{G} \to \mathcal{G}$ is an efficient Dehn twist representative of $\mathcal{D}$, with respect to some identification isomorphism $\theta : \mathcal{F}_n \to \pi_1(\mathcal{G}, v_0)$ for some vertex $v_0$ of $\mathcal{G}$.

For some element $w \in F_n$ let $W \in \Pi(\mathcal{G})$ be the corresponding element in the Bass group of $\mathcal{G}$, i.e. $W = \theta(w) \in \pi_1(\mathcal{G}, v_0) \subset \Pi(\mathcal{G})$.

We say that $w$ is $\mathcal{D}$-reduced if $W$ is $\mathcal{D}$-reduced.

(2) Recall that $\theta(w)$ is called $D$-reduced if the element $W$ is reduced as word in $\Pi(\mathcal{G})$, and if its $\mathcal{G}$-length can not be shortened by $D$-conjugation, i.e. by passing over to a word $V^{-1} W D(V) \in \pi_1(\mathcal{G}, v_1) \subset \Pi(\mathcal{G})$, for some vertex $v_1$ of $\mathcal{G}$. It follows from our considerations in the proof of Proposition 6.1 that in this case $w$ is $\mathcal{T}$-reduced and cyclically $\mathcal{T}$-reduced.

(3) If $W$ is not $D$-reduced, then we can follow the procedure indicated in Definition 2.11 and Remark 2.15 to perform iteratively elementary $D$-reductions until we obtain a new word $W' \in \pi_1(\mathcal{G}, v_1) \subset \Pi(\mathcal{G})$ which is $D$-reduced, for a possibly different vertex $v_1$. In this case we change our identification isomorphism $\theta$ corresponding to the performed $D$-reductions to obtain a new identification $\theta' : \mathcal{F}_n \to \pi_1(\mathcal{G}, v_1)$ with respect to which $w$ is $\mathcal{D}$-reduced.

(4) Recall that a $D$-reduced word $W \in \Pi(\mathcal{G})$ is $D$-zero if and only if $W$ has $\mathcal{G}$-length 0, or in other words, $W$ is contained in some vertex group $G_v$. In this case we say that a word $w \in F_n$ with $\theta(w) = W$ is $D$-zero.

We thus note that any $w \in F_n$ which is $\mathcal{D}$-reduced (possibly with respect to a modified identification isomorphism $\theta'$ as in (3) above) but not $D$-zero is $\mathcal{T}$-reduced, cyclically $\mathcal{T}$-reduced, and of $\mathcal{T}$-length $|w|_{\mathcal{T}} \geq 1$.

Let $\mathcal{D} \in Aut(F_n)$ be a Dehn twist automorphism, recall that for any element $w \in F_n$ and any integer $n \geq 1$ we denote by $\mathcal{D}^{(n)}(w)$ the iterated product, defined through:

$$\mathcal{D}^{(k)}(w) := w \mathcal{D}(w) \mathcal{D}^2(w) \ldots \mathcal{D}^{k-1}(w),$$

and the partial iterated product is given by

$$\mathcal{D}^{(k_1,k_2)}(w) := \mathcal{D}^{k_1}(w) \mathcal{D}^{k_1+1}(w) \ldots \mathcal{D}^{k_2}(w).$$

Proposition 6.5. Let $\mathcal{D} \in Aut(F_n)$ be a Dehn twist automorphism, and denote by $\mathcal{T}$ the set of “twistors” defined in Proposition 6.1. Let $w \in F_n$ be a $\mathcal{D}$-reduced word which is not $D$-zero, i.e. $|w|_{\mathcal{T}} \neq 0$. Then the combinatorial length of $\mathcal{D}^{(k)}(w)$ has quadratic growth with respect to $k$, i.e. one can find constant $C_1$ such that

$$|\mathcal{D}^{(k)}(w)| \simeq C_1 k^2.$$
Proof. It follows from Proposition 6.1 that \( w \) admits a \( \mathcal{T} \)-reduced decomposition \( w = w_0y_1^0w_1y_2^0w_2 \ldots y_q^0w_q \) with \( w_i \in F_n \) and \( y_i \in \mathcal{T} \) which satisfies that \( \mathcal{D}^k(w) = c_0y_1^1c_1 \ldots c_{q-1}y_q^k c_q \).

It follows immediately from Proposition 6.19 that there exist constants \( N_0 \geq 0 \) and \( K_0 \) such that for \( k \geq N_0 \) we have:

\[
|\mathcal{D}^k(w)| \geq \sum_{i=1}^q k\|y_i\| + (q - 1)K_0.
\]

Since \( w \) is \( \mathcal{D} \)-reduced, Remark 6.3 shows that the cancellation in between \( \mathcal{D}^j(w)\mathcal{D}^{j+1}(w) \) is bounded by some constant \( K_1 \).

By taking \( K'_0 = \min\{K_0, K_1\} \), we obtain that, for \( N_0 \leq k' \leq k \),

\[
|\mathcal{D}^{(k',k)}(w)| \geq \sum_{j=k'}^k \sum_{i=1}^q j\|y_i\| + (kq - k'q - 1)K'_0.
\]

Since \( q \geq 1 \), the cancellation bounds \( (kq - k'q - 1)K'_0 \) grows linearly with respect to \( k \).

In particular, we may take \( k' = N_0 \) hence

\[
|\mathcal{D}^{(N_0,k)}(w)| \geq \sum_{j=N_0}^k \sum_{i=1}^q j\|y_i\| + (kq - N_0q - 1)K'_0
\]

\[
= \frac{k(k - N_0)}{2} \sum_{i=1}^q \|y_i\| + (kq - N_0q - 1)K'_0
\]

and

\[
|\mathcal{D}^{(k)}(w)| \geq \frac{k(k - 1)}{2} \sum_{i=1}^q \|y_i\| + (kq - N_0q - 1)K'_0 - |\mathcal{D}^{(N_0)}(w)|.
\]

On the other hand, for all \( k \in \mathbb{N} \) we always have

\[
|\mathcal{D}^{(k)}(w)| \leq \sum_{j=1}^k \sum_{i=1}^q j|y_i| + \sum_{j=1}^k \sum_{i=0}^q |c_i| = \frac{k(k - 1)}{2} \sum_{i=1}^q |y_i| + k \sum_{i=0}^q |c_i|
\]

Together these two inequalities give \( |\mathcal{D}^{(k)}(w)| \simeq C_1k^2 \) for some \( C_1 > 0 \).

\( \square \)

Remark 6.6. Let \( N_0 \) be as above. Denote

\[
B = \mathcal{D}^{(N_0)}(w) = wD(w)D^2(w) \ldots D^{N_0-1}(w).
\]

We can now find \( N_1 > N_0 \in \mathbb{N} \) large enough so that the following two conditions hold:

1. Let \( w_1 \) be the prefix of \( \mathcal{D}^{(N_0,N_1)}(w) \) which ends with \( y_{q-1} \) such that \( |B| \leq |w_1| \).
2. The number \( N_1 \) is large enough so that \( |y_q^{N_1-1}| \geq |w_1| + |c_q| + |c_{q-1}| \).
These two conditions do guarantee that the cyclic cancellation of $D^{(N_1)}(w)$ cannot proceed into the subword
\[ w_1^{-1}D^{(N_0,N_1)}(w) = c_{q-1}y_q^{i_q}c_q \cdots c_{q-1}y_q^{N_1}c_q \]
further than $c_{q-1}y_q^{i_q}$ on the left and $y_q^{N_1}c_q$ on the right, as otherwise a subword of length $|y_q|$ of $y_q^{i_q}$ would cancel against a subword of $y_q^{N_1}$, which is impossible since $w^{-1} \neq vwv^{-1}$ in $F_n$, for any $w \neq 1$.

Hence we obtain from the above arguments that also the cyclic length $\|D^{(k)}(w)\|$ has quadratic growth with respect to $k$.

7. Main Result and Theorem

The following is a slightly stronger version of what has been stated as Theorem 1.1 in the Introduction.

**Theorem 7.1.** Let $\mathcal{G}$ be a minimal graph-of-groups with trivial edge groups, and let $H : \mathcal{G} \rightarrow \mathcal{G}$ be a graph-of-groups automorphism which acts trivially on the underlying graph $\Gamma = \Gamma(\mathcal{G})$.

Assume that for some vertex $v$ of $\Gamma$ the vertex group $G_v$ is a free group, that the induced vertex group automorphism $H_v : G_v \rightarrow G_v$ is a Dehn twist automorphism, and that for some edges $e$ of $\Gamma$ with endpoint $\tau(e) = v$ the $H$-correction term $\delta_e$ is not $H_v$-zero.

Then the induced outer automorphism $\hat{H}$ of $\pi_1 \mathcal{G}$ has at least quadratic growth.

**Proof.** By Proposition 5.3 it suffices to show that for $w = \delta_e$ one can find an element $u \in G_v$ such that there is a subsequence of $|H_v^{(k)}(w^{-1})H_v^{k}(u)H_v^{(-k)}(w)|$ which grows quadratically.

Since by assumption the correction term $w = \delta_e$ is not $H_v$-zero, we can apply Proposition 6.5 to obtain that the length of the iterated product $H_v^{(-k)}(w)$ grows at least quadratically.

One then uses Proposition 6.1 (2) to show that the subgroup $\text{Fix}(H_v)$ of all fixed elements of $H_v$ has rank at least 2. This enables us to find via Lemma 4.8 an element $u \in \text{Fix}(H_v)$ such that for infinitely many indices $n_i \geq 0$ the cancellation in the product $H_v^{(n_i)}(w^{-1})H_v^{n_i}(u)H_v^{(-n_i)}(w) = H_v^{(-n_i)}(w^{-1})uH_v^{(-n_i)}(w)$ is uniformly bounded, so that from the previous paragraph we obtain that their lengths grow at least quadratically.

Recall from Definition 3.7 (b) that a partial Dehn twist $H : \mathcal{G} \rightarrow \mathcal{G}$ relative to a family of local Dehn twists is given, for any vertex $v$ of $\mathcal{G}$, through an identification isomorphism $G_v \cong \pi_1 \mathcal{G}_v$ and a “local” Dehn twist representatives $D_v : \mathcal{G}_v \rightarrow \mathcal{G}_v$, which we can assume without loss of generality to be efficient. We say that for any edge $e$ of $\mathcal{G}$ the correction term $\delta_e$ is locally zero if it is $D_{\tau(e)}$-zero.

Then the last theorem gives directly:
Corollary 7.2. Let $\hat{\varphi} \in \text{Out}(F_n)$ be represented by a partial Dehn twist $H : \mathcal{G} \to \mathcal{G}$ relative to a family of local Dehn twists. Assume that for some edge $e$ of $\mathcal{G}$ the correction term $\delta_e$ is not locally zero.

Then $\hat{\varphi}$ has at least quadratic growth. \hfill \Box

As a final remark we want to point out that Corollary 1.2 is indeed a direct consequence of the above corollary together with the main result of [10], which states that, in the situation of Corollary 7.2 if all of the correction terms for the edges of $\mathcal{G}$ are locally zero, then $H$ can be blown-up at the local Dehn twists to give a Dehn twist representative of the automorphism $\hat{\varphi}$.
