We consider a charged Brownian gas under the influence of external and non-uniform electric, magnetic and mechanical fields, immersed in a non-uniform bath temperature. With the collision time as an expansion parameter, we study the solution to the associated Kramers equation, including a linear reactive term. To first order we obtain the asymptotic (overdamped) regime, governed by transport equations, namely: for the particle’s density, a Smoluchowski-reactive like equation; for the particle’s momentum density, a generalized Ohm’s like equation; and for the particle’s energy density, a Maxwell-Cattaneo like equation. Defining a nonequilibrium temperature as the mean kinetic energy density, and introducing Boltzmann’s entropy density via the one particle distribution function, we present a complete thermohydrodynamical picture for a charged Brownian gas. We probe the validity of the local equilibrium approximation, Onsager relations, variational principles associated to the entropy production, and apply our results to: carrier transport in semiconductors, hot carriers and Brownian motors. Finally, we outline a method to incorporate non-linear reactive kinetics and a mean field approach to interacting Brownian particles.

1: Introduction

The ubiquitous Brownian motion [1]-[8] remains an outstanding paradigm in modern physics [9]. The theoretical framework [10,11] consisting of Kramers equation (a Fokker-Planck equation in phase space), Smoluchowski equation (asymptotic or overdamped contraction of the latter) and the associated stochastic Langevin equation, have been widely applied to diverse problems, such as: Brownian motion in potential wells, chemical reactions rate theory, nuclear dynamics, stochastic resonance, surface diffusion, general stochastic processes and evolution of nonequilibrium systems, in both classical and quantum contexts. More recent applications include thermodynamics of small systems, molecular motors, chemical and biological nanostructures, mesoscopic motors power output and efficiency, and the fractional Kramers equation applied to anomalous diffusion. Concerning reviews and applications, we mention some representative but by no means an exhaustive list of references [10]-[60], some monographs [61]-[70] in addition to the “founding papers” [3]-[8]. In his celebrated 1943 Brownian motion paper [11], Chandrasekhar outlined the method for solving a Brownian particle in a general field of force. It took approximately sixty years to report exact solutions for the Brownian motion of a charged particle in uniform and static electric and/or magnetic fields [71]-[85] (see also some previous related works [86,87]).

In Section 2 we generalize and extend previous work [75,77] and consider a charged Brownian particle in general field of force (including magnetic fields), in an inhomogeneous medium (a nonuniform/nonisothermal bath temperature profile [88]-[113]). Furthermore we include a reactive linear term (BGK like [114]-[117]) and obtain a general associated Kramers equation. In Section 3 we expand the solution generalizing a previous result [75] yielding recursive relations (for other expansions in the literature see for example [64],[73] and [118]-[120]. In Section 4 we use these recursive
relations to obtain the Hydrothermodynamical picture of Brownian motion. In Section 5 we present some straightforward applications namely, the linear Onsager-like expansions for the entropy production for Brownian motion, generalized Shockley carrier transport equations, hot carrier transport and chemically reacting Brownian gases. Finally in Section 6 our concluding remarks include further applications of our results.

2: Generalized Kramers equation for a Brownian charged particle

Consider a charged Brownian gas composed of \( N \) particles (mass \( m \), charge \( q \)) in an inhomogeneous bath temperature profile, under the influence of external fields (not necessarily uniform in space, nor time independent). Our starting point is Kramers equation for the one particle distribution function \( P(\mathbf{x}, \mathbf{v}, t) \), at position \( \mathbf{x} \), with \( \mathbf{v} \) and at time \( t \), being in contact with an inhomogeneous bath temperature \( T(\mathbf{x}) \) (natural units \( k_B = 1 \)) and under a general field of force: a mechanical contribution \( \mathbf{F}_{\text{mec}} = -\nabla U \), with \( U = -x \mathbf{F}_{\text{ext}}(t) + U_{\text{mec}} \) (allowing for potential derived forces and non potential homogeneous external forces); an electric contribution \( \mathbf{F}_{\text{elec}} = q \mathbf{E} = q \nabla \phi \) and a magnetic contribution (Lorentz’s velocity dependent force) \( \mathbf{F}_{\text{mag}} = \frac{q}{2} \mathbf{v} \times \mathbf{B} \). The total external force can be casted as a potential derived force plus a velocity contribution

\[
\mathbf{F}(\mathbf{x}, \mathbf{v}, t) = \mathbf{F}_{\text{mec}}(\mathbf{x}, t) + \mathbf{F}_{\text{elec}}(\mathbf{x}, t) + \mathbf{F}_{\text{mag}}(\mathbf{x}, t) = \mathbf{F}_{\text{pot}} - m \omega \times \mathbf{v} \tag{1}
\]

where

\[
\mathbf{F}_{\text{pot}} = -\nabla U \\
U = -x \mathbf{F}_{\text{ext}}(t) + U_{\text{mec}} + q \phi \\
\omega = \frac{q}{mc} \mathbf{B}
\]

For a charged Brownian particle, Kramers equation for the distribution \( P(\mathbf{x}, \mathbf{v}, t) \) reads (see for example [73, 75, 77])

\[
\frac{\partial P}{\partial t} + \mathbf{v} \frac{\partial P}{\partial \mathbf{x}} + \frac{1}{m} \mathbf{F}(\mathbf{x}, \mathbf{v}, t) \frac{\partial P}{\partial \mathbf{v}} = \frac{1}{\tau} \frac{\partial}{\partial \mathbf{v}} \left( \mathbf{v} P + \frac{T(\mathbf{x})}{m} \frac{\partial P}{\partial \mathbf{v}} \right) = \frac{1}{\tau} \frac{\partial}{\partial \mathbf{v}} \left( \tau^{-1} \mathbf{v} P + \Gamma \frac{\partial P}{\partial \mathbf{v}} \right) \tag{3}
\]

where the Brownian collision time is denoted by \( \tau \), the mobility by \( \lambda \), defined by the relation \( m \lambda = \tau \) (\( \gamma = \lambda^{-1} \) is Stokes friction coefficient). The mobility and the diffusion coefficient \( D \), are both related to the bath temperature via the celebrated fluctuation dissipation theorem \( D = k_B T \) (Sutherland-Einstein relation [4, 5]). Notice that in our scheme the mobility (or \( \tau \)) may also have a position dependent profile; and \( \Gamma \) is related to fluctuations, as given by \( D = \tau^2 \Gamma \). The left hand side of the previous equation may be denoted as the streaming operator \( \mathbb{L} \), operating on \( P \) along the (Newtonian) trajectory \( \mathbf{v} = \dot{\mathbf{x}} \), \( m \dot{\mathbf{v}} = \mathbf{F} \). The right hand side is denoted as the Fokker Planck collision kernel operator \( \mathbb{K}_{FP} \) where the first term is the contribution of the (dissipative) Stokes force \( \mathbf{F}_S = -\gamma \mathbf{v} \) and the second term the fluctuating contribution, so in explicit form we have

\[
\mathbb{L}(\mathbf{F}) = \frac{\partial}{\partial t} + \mathbf{v} \frac{\partial}{\partial \mathbf{x}} + \frac{1}{m} \mathbf{F}(\mathbf{x}, \mathbf{v}, t) \frac{\partial}{\partial \mathbf{v}} \tag{4}
\]

\[
\mathbb{K}_{FP}(\lambda, \Gamma) = \frac{\partial}{\partial \mathbf{v}} \left( \tau^{-1} \mathbf{v} + \Gamma \frac{\partial}{\partial \mathbf{v}} \right) \tag{5}
\]

and we may cast equation (3) in the compact form

\[
\mathbb{L}(\mathbf{F}) P(\mathbf{x}, \mathbf{v}, t) = \mathbb{K}_{FP}(\tau, \Gamma) P(\mathbf{x}, \mathbf{v}, t) \tag{6}
\]

Let us define a tensorial Stokes force [75, 77] as

\[
\mathbf{F}_{TS} = -\lambda^{-1} \mathbf{v} - m \omega \times \mathbf{v} = -M^{-1} \mathbf{v} \tag{7}
\]
where the magneto mobility tensor $\mathbf{M}$ is defined (when operating over an arbitrary vector $\mathbf{V}$) as

$$\mathbf{M}(\tau, \omega)\mathbf{V} = \lambda \frac{\mathbf{V} + \tau \mathbf{V} \times \omega + \tau^2 \omega (\omega \cdot \mathbf{V})}{1 + \tau^2 \omega^2}$$

(8)

In particular we notice the familiar form [77] for the case $\mathbf{B} = B_0 z$

$$\mathbf{M}(\tau, \omega) = \frac{\lambda}{1 + \tau^2 \omega^2} \begin{pmatrix} 1 & \tau \omega & 0 \\ -\tau \omega & 1 & 0 \\ 0 & 0 & 1 + \tau^2 \omega^2 \end{pmatrix}$$

(9)

It was shown [74, 77] that by defining such a tensorial Stokes force equation (6) is equivalent to

$$\mathcal{L}(U)P(x, v, t) = \mathbb{K}_{FP}(\mathbf{M}, \Gamma)P(x, v, t)$$

(10)

thus, the streaming operator includes only de (scalar) potential derived force and the magnetic contribution enters as a dissipative non diagonal contribution in the collision kernel (for convenience we have denoted $\mathcal{L}(U) = \mathcal{L}(\mathbf{F}_{pot} = -\nabla U)$).

Now as in [75, 115] we add a BGK contribution to the collision kernel denoted by $\mathbb{K}_{BGK}$. This collision operator is single relaxation time approximation [113]-[117] where the distribution $P$ relaxes (collision time $\tau_0$) to a prescribed distribution $P_0$, the latter instantly equilibrated in the velocity coordinates, to the bath temperature, thus

$$P_0(x, v, t) = n_0(x, t)f_0(v, T(x)) \quad f_0(v, m, T(x)) = \left(\frac{m}{2\pi T(x)}\right)^{\frac{3}{2}} \exp\left(-\frac{mv^2}{2T(x)}\right)$$

(11)

where $f_0$ is a (normalized) Maxwellian distribution, $n_0$ is a prescribed density profile. For the Brownian gas we define particle density as $n(x, t) = \int dv P(x, v, t)$ where $N = \int dx n(x, t)$. In general $n_0(x, t)$ needs not to satisfy $N = \int dx n_0(x, t)$ (BGK is not a particle conserving approximation). The BGK kernel is given by

$$\mathbb{K}_{BGK}(n_0(x, t), \tau_0, k)P(x, v, t) = -\frac{1}{\tau_0} (P(x, v, t) - P_0(x, v, t))$$

(12)

and represents the simple chemical reaction $A \leftrightarrow A_0$, both compounds with particle density $n(x, t)$ and $n_0(x, t)$, respectively, and with forward (backward) rate $k_+ (k_-)$, we have

$$\left(\frac{\partial n(x, t)}{\partial t}\right)_r = \int dv \mathbb{K}_{BGK} P(x, v, t) = -k_+ n(x, t) + k_- n_0(x, t) = -\left(\frac{\partial n_0(x, t)}{\partial t}\right)_r$$

(13)

where we have defined the rates as $k_+ = k_- = \tau_0^{-1}$. Then, Kramers equation for a charged Brownian particles under a general field of force in an inhomogeneous medium, including a linear reactive term, is compacted as

$$\mathcal{L}(U)P(x, v, t) = \mathbb{K}_{FP}(\mathbf{M}, \Gamma)P(x, v, t) + \mathbb{K}_{BGK}(n_0(x, t), \tau_0)P(x, v, t) = \mathbb{K}P(x, v, t)$$

(14)

This is a generalized kinetic equation in the Fokker-Planck (FP) context for a charged Brownian particle. The **novel aspect in our approach** is to include on an equal footing the following aspects: An external magnetic field (a velocity dependent force) rarely considered in the Brownian context; an inhomogeneous bath temperature profile $T(x)$ and, in addition to the particle conserving FP collision kernel, we add a non conserving particle collision contribution (a generalized BGK mechanism), enabling our approach to incorporate chemical reactions and/or generation-recombination processes (for the latter we may consider an inhomogeneous collision time profile $\tau_0(x)$).
3: Recursive expansion of Kramers equation

We expand Kramers equation (14) in order to obtain a recursive solution. Some expansion methods include [118–120], and we review a method outlined in ref. [75]. The expansion is casted as

\[ P(x,v,t) = \sum_{n,m,l=0}^{\infty} \Psi_{nm\ell}(x,t) \Phi_{nm\ell}(w) \]

where \( \Phi_{nm\ell}(w) = \phi_n(w_x) \phi_m(w_y) \phi_\ell(w_z) \) is the product of (normalized) Hermite functions [121]. Following [75] and using appropriate recursion relations [121], equation (14) reduces to a difference-differential recursive system of equations for the \( \Psi' s \) (\( v \) has been integrated out). These recursion relations are better displayed in the compact form, and as before [75] we allow for a slowly time varying (compared with \( \tau \)) external temperature field \( T(x,t) \).

\[ k \frac{\tau}{\tau_0} n_0 \delta_{n_0,0} = \tau \omega \cdot A^* \times A Z_n + (A^* A + \tau R) Z_n \quad n = (n_1, n_2, n_3) \]

where

\[ R = \frac{\partial}{\partial t} + \frac{1}{\tau_0} + \nabla A^* + \frac{v^2}{2 T} \left( \nabla A + A \frac{\nabla U}{T} + A^2 \left( (v^2 A + A^* \frac{\nabla T}{2 T} + \frac{1}{2} \frac{\partial T}{\partial t} \right) \right) \]

with \( \nabla = \frac{\partial}{\partial x} \) and

\[ Z_n = \frac{v^{n_1+n_2+n_3} \Psi_{n_1 n_2 n_3}}{\sqrt{n_1! n_2! n_3!}} \]

The asymmetric lowering and raising operators \( A, A^* \) are defined respectively by

\[ A_1 Z_n = Z_{n_1-1,n_2,n_3} \quad A_1^* Z_n = (1 + n_1) Z_{n_1+1,n_2,n_3} \]
\[ A_2 Z_n = Z_{n_1,n_2-1,n_3} \quad A_2^* Z_n = (1 + n_2) Z_{n_1,n_2+1,n_3} \]
\[ A_3 Z_n = Z_{n_1,n_2,n_3-1} \quad A_3^* Z_n = (1 + n_3) Z_{n_1,n_2,n_3+1} \]

4: Hydrothermodynamics of Brownian Motion

We now proceed in a standard fashion [122–125] and define some relevant moments of the distribution \( P(x,v,t) \). The usual (lower) moments are: particle density \( n(x,t) \), particle flux vector density \( J_M(x,t) \), pressure tensor density \( \Pi(x,t) \), kinetic energy density \( E(x,t) \), energy flux vector density \( J_E(x,t) \) and the total energy flux vector density \( J_Q(x,t) \). Some useful auxiliary quantities are also defined, namely: mass density \( \rho(x,t) \), mass flux density \( J_\rho(x,t) \), charge flux density \( J_q(x,t) \), scalar pressure \( p(x,t) \) and the stream velocity \( u(x,t) \). All of the above are defined by:

\[ n(x,t) = \int dv P(x,v,t), \quad \rho(x,t) = mn(x,t) \]
\[ J_M(x,t) = \int dv P(x,v,t) n(x,t) u(x,t) \]
\[ J_\rho(x,t) = m J_M(x,t), \quad J_q(x,t) = q J_M(x,t) \]

\[ \Pi(x,t) = m \int dv vv P(x,v,t), \quad p(x,t) = \frac{1}{3} \sum_{i=1}^{3} \Pi_{ii}(x,t) \]
\[ \Pi_{ii}(x,t) = m \int dv (v - u)(v - u) P(x,v,t) = \Pi(x,t) - \rho u(x,t) u(x,t) \]
\[ E(x,t) = \frac{1}{2} m \int d\mathbf{v} |\mathbf{v}|^2 P(x,\mathbf{v},t) = \frac{3}{2} \rho(x,t) \] (24)

\[ \mathbf{J}_E(x,t) = \frac{1}{2} m \int d\mathbf{v} \mathbf{v} |\mathbf{v}|^2 P(x,\mathbf{v},t) \] (25)

\[ \mathbf{J}_Q(x,t) = \int d\mathbf{v} \left( \frac{1}{2} m |\mathbf{v}|^2 + U(x,t) \right) P(x,\mathbf{v},t) = \mathbf{J}_E(x,t) + U(x,t) \mathbf{J}_M(x,t) \] (26)

These relevant moments can be readily associated with the expansion coefficients \( Z_n \), see equation (18)

\[ n(x,t) = Z_{000}, \quad \Phi_{000}(w) = f_0(v,m,T(x)) \] (27)

\[ \mathbf{J}_M(x,t) = \begin{pmatrix} Z_{100} \\ Z_{010} \\ Z_{001} \end{pmatrix} \] (28)

\[ \Pi(x,t) = n(x,t) T(x) + m \begin{pmatrix} 2Z_{200} & Z_{110} & Z_{101} \\ Z_{110} & 2Z_{020} & Z_{011} \\ Z_{101} & Z_{011} & Z_{002} \end{pmatrix} \] (29)

\[ \mathbf{J}_E(x,t) = \frac{5}{2} T(x) \mathbf{J}_M(x,t) + m \begin{pmatrix} 3Z_{300} + Z_{120} + Z_{102} \\ Z_{210} + 3Z_{030} + Z_{012} \\ Z_{201} + Z_{021} + 3Z_{003} \end{pmatrix} \] (30)

Then, the recursive relations, equation (18), as outlined in [75] can be compacted into a set of balance equations (conservation of mass, momentum and energy, respectively) yielding the hydrodynamical picture. For the particle density the recursive relations yields

\[ \frac{\partial n}{\partial t} + \nabla \mathbf{J}_M = -k_+ n + k_- n_0 = \left( \frac{\partial n}{\partial t} \right)_{\text{reac}} \] (31)

a generalized Smoluchowski equation with a dissipative (reactive) term; for the particle flux we obtain

\[ \frac{\partial \mathbf{J}_M}{\partial t} + \left( \frac{1}{\tau} + \frac{1}{\tau_0} \right) \mathbf{J}_M = \mathbf{J}_M \times \mathbf{\omega} - \frac{n}{m} \nabla U - \frac{1}{m} \nabla \Pi \] (32)

if casted in terms of the stream velocity, and using equation (31) we obtain the Navier-Stokes equation for Brownian flow

\[ \frac{\partial \mathbf{u}}{\partial t} \mathbf{+} (\mathbf{u}\nabla) \mathbf{u} \mathbf{+} \frac{1}{\rho} \nabla \Pi = \frac{1}{m} (-\nabla U \mathbf{+} \mathbf{F}_{\text{diss}}), \quad \mathbf{F}_{\text{diss}} = - \left( \mathbf{A}^{-1} \mathbf{+} \frac{\mathbf{m} \mathbf{n}_0}{\tau_0 n} \right) \mathbf{u} \] (33)

other equivalent versions of equation (32) in terms of the charge flux density and with \( \mathbf{F}_{\text{ext}} = 0 \) in equation (2) are

\[ \tau^* \frac{\partial \mathbf{J}_q}{\partial t} + \mathbf{J}_q = \sigma^* \left( \mathbf{E} + \mathbf{R} \mathbf{J}_q \times \mathbf{B} \right) - \frac{q \tau^* n}{m} \nabla U_{\text{mech}} - \frac{q \tau^*}{m} \nabla \Pi \] (34)
\[ J_q = \sigma^* \Lambda^* (\tau^*, \omega) \left( E - \frac{1}{q} \nabla U_{\text{mec}} - \frac{1}{qn} \nabla \Pi \right) - mA(\tau^*, \omega) \frac{\partial J_q}{\partial t} \]  

(35)

a generalized Ohm’s law [124] where the effective relaxation time \( \tau^* \), the effective conductivity \( \sigma^* \) and Hall’s coefficient are respectively given by

\[
\frac{1}{\tau^*} = \frac{1}{\tau} + \frac{1}{\tau_0}, \quad \sigma^*(x,t) = q^2 \tau^* n \frac{m}{m}, \quad R_H(x,t) = \frac{1}{nqc}
\]

(36)

Finally we obtain the energy balance equation

\[
\frac{\partial E}{\partial t} + \nabla J_E = -J_M \nabla U - \frac{1}{\tau_0} (E - E_0) \quad E_0 = \frac{3}{2} n_0 T
\]

(37)

Thermodynamics is introduced by defining the kinetic temperature \( \Theta \) [75, 77, 126] (a generalization of the equipartition theorem, assuming the Brownian particle to have only translational degrees of freedom) defined as

\[
E(x,t) = \frac{3}{2} n(x,t) \Theta(x,t)
\]

(38)

when substituted into (37) yields

\[
\frac{3}{2} n \frac{\partial \Theta}{\partial t} + \nabla J_Q = \left( \frac{3}{2} \Theta + U \right) \nabla J_M - \frac{3}{2} \frac{1}{\tau_0} n_0 (\Theta - T)
\]

(39)

We define entropy density \( S \) and the entropy flux density \( J_S \) respectively as [73, 75, 77]

\[
S(x,t) = -\int d\mathbf{v} P(x, \mathbf{v}, t) \ln \kappa P(x, \mathbf{v}, t)
\]

\[
J_S(x,t) = -\int d\mathbf{v} \mathbf{v} P(x, \mathbf{v}, t) \ln \kappa P(x, \mathbf{v}, t)
\]

(40)

where the constant \( \kappa \) (\( \ln \kappa = -1 + 3 \ln \frac{h}{m} \)) is chosen such that under equilibrium conditions \( S \rightarrow S_{eq} \) [75, 127] (for a simple ideal gas, where \( h \) is Planck’s constant).

\[
S_{eq}(n_{eq}, T_{eq}) = n_{eq} \left( \frac{5}{2} + \ln \frac{n_Q(T_{eq})}{n_{eq}} \right), \quad n_Q(T_{eq}) = \left( \frac{2\pi m}{h^2} T_{eq} \right)^{\frac{3}{2}}
\]

(41)

An entropy balance equation is readily obtained [123], yielding an expression for the entropy production \( \Sigma_S \) solely in terms of the particle distribution

\[
\frac{\partial S(x,t)}{\partial t} + \frac{\partial J_S(x,t)}{\partial x} = \Sigma_S = -\int d\mathbf{v} (1 + \ln \kappa P(x, \mathbf{v}, t)) \kappa(P)
\]

(42)

Finally [73, 75] we define the various thermodynamical potential densities, namely: \( F \) (Helmholtz), \( G \) (Gibbs), \( \mu^I \) (intrinsic chemical potential), and \( \mu \) (total chemical potential), respectively given by [127]

\[
F(x,t) = E(x,t) - \Theta(x,t) S(x,t)
\]

\[
G(x,t) = F(x,t) + p(x,t) = n(x,t) \mu^I(x,t)
\]

\[
\mu(x,t) = \mu^I(x,t) + U(x,t)
\]

(43)

the equilibrium expression for the chemical potential is [127]
\[ \mu_{eq}(n_{eq}, T_{eq}) = -T_{eq} \ln \frac{n_Q(T_{eq})}{n_{eq}} \] (44)

All moments, or equivalently, the expansion coefficients \( Z_n, \ n \neq 0 \), see equation (18), are expandable in powers of \( \tau \), when solving the recurrence relation (16), and considering \( \tau \omega \) as an independent parameter. Hereafter, when referring to expansion order, we mean in powers of \( \tau \), for example, the magneto mobility tensor \( M \) in equation (8), is a first order quantity. We further expand the expansion coefficients as

\[ Z_n = \sum_{k=1}^{\infty} \tau^k Z_n^{(k)} \] (45)

For \( |\nabla T| \neq 0 \) we have \( Z_n^{(k)} \equiv 0 \) for \( k < \text{integer} \left[ \frac{N+2}{3} \right] \). For the isothermal case \( |\nabla T| = \frac{\partial T}{\partial t} \equiv 0 \) we have \( Z_n^{(k)} \equiv 0 \) for \( k < N \).

Now, we discuss several relevant cases concerning the heat bath interaction with the Brownian gas (a gas of real particles or some collective property of a given macroscopic system). In order to simplify the discussion we denote the Brownian gas as the solute and the heat bath as the solvent (the fluid in which the Brownian particle is immersed). As the solute fluctuates and dissipates in the solvent, towards an equilibrium (or non-equilibrium steady) state, the solute temperature \( \Theta(x,t) \) evolves according to the Brownian dynamics (given by equation (3) adjusting itself to the solute temperature \( T(x,t) \) and the external fields acting on the solute. On the other hand the solvent temperature is perturbed by the solute temperature, a very weak interaction indeed, since as a heat bath, \( T(x,t) \) relaxes instantly (or very fast compared with \( \tau \)) to a prescribed heat bath temperature profile \( T_{in}(x) \), the latter a stationary function to be considered as both an initial and a boundary condition. We realize that \( \nabla T \) is not controlled at all in the interior of the system but only on its surfaces. In the bulk, the solute performs its Brownian evolution, while the solvent temperature relaxes (very fast) to the prescribed profile. This is a unsatisfactory state of affairs since in the bulk, the control parameter \( T_{in}(x) \) evolves as \( T(x,t) \) perturbed by the solute, at temperature \( \Theta(x,t) \), which in turn evolves following \( T(x,t) \), thus a clear cut distinction between controlled external (thermal) fields and the resulting (thermal) fluxes cease to exist (125).

We analyze three simple cases, with no attempt to model the heat bath at this point (see for example [65, 128]).

- Strictly Isothermal Bath, with \( T(x,t) = T_{in}(x) = T_R \)
- Strictly Stationary Inhomogeneous Bath with \( T(x,t) = T_{in}(x), |\nabla T| \neq 0 \), and
- Weakly Interacting Bath, first order in \( \tau \), where \( T(x,t) = T_{in}(x) \) only at the boundaries.

From the recursion relations (15), for the strictly isothermal case, the solute temperature has a second order correction (in \( \tau \)), already obtained by us, as an asymptotic solution to a particular isothermal exact solution (77). We present our result, as in (77), in terms of the stream velocity \( u(x,t) \), in turn expressed as a magneto covariant derivative

\[ \Theta(x,t) = T_R + \frac{1}{3} m u^2(x,t) \] (46)

where

\[ u(x,t) = -\frac{T_R}{n(x,t)} M \exp \left( -\frac{U(x,t)}{T_R} \right) \nabla \left[ n(x,t) \exp \left( \frac{U(x,t)}{T_R} \right) \right] \] (47)

This is a generalization of Shockley’s expression for hot carriers effective temperature (129, 130). Shockley’s result coincides with our result at zero magnetic field and homogeneous carrier concentration (provide we identify the hot carrier with the solute, at temperature \( \Theta \), and the solvent with the lattice, at temperature \( T_R \)).

For the weakly interacting bath, to first order in \( \tau \), we obtain

\[ \Theta(x,t) = T(x,t) + \frac{\tau}{2} \frac{\partial T(x,t)}{\partial t} = T(x,t + \frac{\tau}{2}) \] (48)

identical to equation (7.2) obtained by [129], provided we identify the solute with electrons, at temperature \( \Theta \) and the solvent with the lattice, at temperature \( T \).
5: Applications

A)- For the strictly isothermal bath case, we present the second order results, from the recursion relations (40) and by expanding (40). Our results are equivalent to the asymptotic regime for an exact solution [77]: the local equilibrium approximation [131]-[135] is not fulfilled [136]; in particular the entropy density and the chemical potential are given, respectively by the expressions

\[
S(n(x, t), \Theta(x, t)) = S_{eq}(n(x, t), \Theta(x, t)) - \frac{m}{2TR}n(x, t)u^2(x, t)
\]

(49)

\[
\mu(n(x, t), \Theta(x, t)) = \mu_{eq}(n(x, t), \Theta(x, t)) + U(x, t) + \frac{1}{2}mSU^2(x, t)
\]

where the temperature \( \Theta \) and the stream velocity \( u \) are given respectively by equations (46) and (47).

B)- For the strictly stationary inhomogeneous bath case, the local equilibrium approximation holds, in particular the entropy density and the chemical potential are given, respectively by the expressions

\[
S(x, t) = S_{eq}(n(x, t), T_{in}(x))
\]

(50)

\[
\mu(x, t) = \mu_{eq}(n(x, t), T_{in}(x)) + U(x, t)
\]

C)- For the weakly interacting bath, again an as in case A) the local equilibrium approximation does not hold, to first order (in \( \tau \)). The particle flux density is given by the (equivalent) expressions

\[
J_M(x, t) = -n(x, t)M\nabla U(x, t) - M\nabla (\Theta(x, t)n(x, t))
\]

(51)

\[
J_M(x, t) = -n(x, t)M\nabla(U(x, t) + \Theta(x, t)) - D(x, t)\nabla n(x, t),
\]

where \( D = \Theta(x, t)M \) is the magneto-diffusion tensor. The total energy flux density is given by

\[
J_Q(x, t) = \left( \frac{5}{2} \Theta(x, t) + U(x, t) \right)J_M(x, t) - \frac{5}{6}n(x, t)\Theta(x, t)M_1\nabla \Theta(x, t)
\]

(52)

and where we have incorporated, at no cost, an inhomogeneous collision time profile \( \tau(x) \) as well as a space varying magnetic field, with the compact definitions

\[
M_kV = \theta(x) \left( V + \tau_k(x)V \times \omega(x) + \tau_k^2(x)\omega(x) \right) \omega(x) \cdot V)
\]

\[
\theta(x) = \frac{\lambda(x)}{1 + (\tau_k(x)\omega(x))^2} \quad \tau_k(x) = \frac{1}{k} \tau(x)
\]

(53)

\[
M_k(\tau, \omega) = M(\frac{\tau}{k}, \omega) \quad M_1 = M \quad k = 1, 2, ...
\]

Notice that in equations (51) and (52) according to equation (48) \( \Theta(x, t) \) can be substituted by \( T(x, t) \) since the magnetic mobility tensor \( M \), equation (8), is already a first order quantity. With the last observation in mind, we rewrite the “fluxes” in terms of the “forces”, following [125, 133]. Thus, we define the matter and heat “forces” as

\[
X_M(x, t) = -\nabla \left( \frac{\mu}{T} \right) \quad X_Q(x, t) = \nabla \left( \frac{1}{T} \right)
\]

(54)
where
\[ \mu(x, t) = \mu_{\text{eq}}(n(x, t), T(x, t)) + U(x, t) \] (55)
so to first order in \( \tau \) we have the linear flux-force relations
\[ J_M(x, t) = L_{MM}(x, t)X_M(x, t) + L_{MQ}(x, t)X_Q(x, t) \] (56)
\[ J_Q(x, t) = L_{QM}(x, t)X_M(x, t) + L_{QQ}(x, t)X_Q(x, t) \]
where the coefficients are given by
\[ L_{MM}(x, t) = n(x, t)T(x, t)M \]
\[ L_{MQ}(x, t) = L_{QM}(x, t) = n(x, t)T(x, t) \]
\[ L_{QQ}(x, t) = n(x, t)T(x, t) \left( \frac{5}{2}T(x, t) + U(x, t) \right)^2 M + \frac{5}{2}n(x, t)T^3(x, t)M \]
(57)
\[ L^*_{QM}(B) = L_{MQ}(-B) \] (58)
the last equation indicating that Onsager relations are satisfied \[125, 131-135\]. Nevertheless, the Onsager like coefficients do not depend solely on the equilibrium values of the state variables (mass density, temperature). Instead they are functions of the external potentials and nonequilibrium state variables, namely \( n(x, t) \) and \( \Theta(x, t) \), which in turn evolve according to equations (31) and (39) respectively (for simplicity of presentation we omit the spatial and temporal dependence)
\[ \frac{\partial n}{\partial t} = -\nabla J_M - k_+ n + k_- n_0 \] (59)
\[ \frac{3}{2} \frac{n}{\tau_0} \frac{\partial \Theta}{\partial t} = -\left( \frac{5}{2} \nabla \Theta + \nabla U \right) J_M - \Theta \nabla J_M + \frac{5}{6} \nabla n \Theta M_3 \nabla T - \frac{3}{2} \frac{1}{\tau_0} n_0 (\Theta - T) \]
and substituting from equation (48), within the linear approximation (first order in \( \tau \)) we obtain the coupled equations for the evolution of the state variables \( n(x, t) \) and \( T(x, t) \) (or \( \Theta \))
\[ \frac{\partial n}{\partial t} + \frac{1}{\tau_0} (n - n_0) = \nabla M_1 Y = n \nabla U + n \nabla T + T \nabla n \] (60)
\[ \frac{3}{2} \left( n + \frac{\tau n_0}{2\tau_0} \right) \frac{\partial T}{\partial t} + \frac{3\tau n}{4} \frac{\partial^2 T}{\partial t^2} = \left( \frac{5}{2} \nabla T + \nabla U \right) M_1 Y + T \nabla (M_1 Y) + \frac{5}{6} \nabla (M_3 n \nabla T) \] (61)
Equation (60) is a generalized Smoluchowski like advection diffusion reactive equation, and equation (61) is a Maxwell-Cattaneo like heat equation, generalizing Fourier’s heat equation, incorporates inertial effects \[70, 126, 137-139\], as noticed from the time delay character of equation (48), where the time needed for the acceleration of the heat flow is considered.
Thus, even though Onsager relations are satisfied, the coefficient’s dependence on nonequilibrium state variables and external fields, indicates that any variational principle associated with the entropy production \[132, 134, 135, 140, 141\], is not applicable to the present case \[69, 142\].

In the absence of the BGK reactive term, null magnetic field, and for the strictly stationary inhomogeneous bath case, we recover the inhomogeneous media advection-diffusion equation, presented by \[96\] and given by
\[
\frac{\partial n(x,t)}{\partial t} = \nabla \left( \lambda(x) \left[ n(x,t) \nabla U(x) + n(x,t) \nabla T(x) + T(x) \nabla n(x,t) \right] \right)
\] (62)

and for the rigid conductor (constant particle density \(n\)), no reactive term and null external fields, we retrieve the inertial corrections to Fourier’s law, known as the Maxwell-Cattaneo equation [137]-[139] (of the hyperbolic type, known also as the telegrapher’s equation)

\[
\frac{\partial T(x,t)}{\partial t} + \frac{\tau}{2} \frac{\partial^2 T(x,t)}{\partial t^2} = K \left( T(x,t) \nabla^2 T(x,t) + (\nabla T(x,t))^2 \right) = -\nabla J_T(T(x,t))
\] (63)

\[
J_T(T) = KT^3(x,t) \nabla \left( \frac{1}{T(x,t)} \right) = -KT(x,t) \nabla T(x,t) = -\kappa(x,t) \nabla T(x,t),
\] (64)

with \(K = \frac{22}{9} \lambda\). The right hand side of the last equation is known as the fundamental form of Fourier’s law [63].

D)-Carrier transport in semiconductors, in the Brownian scheme, for the strictly stationary inhomogeneous bath case [143, 144]. Consider two Brownian gases, say electrons (density \(n_e\), collision time \(\tau_e\), mobility \(M_e = M(\tau_e, \omega_e)\), effective mass \(m_e\) and charge \(-e\)) and holes (density \(n_h\), collision time \(\tau_h\), mobility \(M_h = M(\tau_h, \omega_h)\), effective mass \(m_h\) and charge \(e\), and with \(m_{e,h} c = \omega_{e,h} |\mathbf{E}|\)). The BGK mechanism is associated in this case to carrier generation-recombination with the respective generation-recombination times \(\tau_{e,v}^0\) and with the \(n^0\)'s the respective equilibrium carrier concentrations. Then, by applying equation (60) we obtain

\[
\frac{\partial n_e}{\partial t} = \nabla M_e (\beta n_e E + n_e \nabla T + T \nabla n_e) - \frac{1}{\tau_e} (n_e - n_e^0)
\]

\[
\frac{\partial n_h}{\partial t} = \nabla M_h (\beta n_h E + n_h \nabla T + T \nabla n_h) - \frac{1}{\tau_h} (n_h - n_h^0)
\] (65)

Shockley’s equations (unidimensional, isothermal, null magnetic field case) are readily recovered [143, 144]. Inhomogeneous generalizations of Shockley’s equations are of current interest [145-152].

E)-Our scheme can readily be generalized for several Brownian gases (\(\alpha = 1, ..., l\)) interacting via non reactive potential \(U_{\alpha \beta}\) and with the usual BGK reactive term associated to each gas. By applying a mean field approximation scheme to a many component Brownian gas [153-154], as worked out in several contexts in [155-161], Kramers system of equations can readily be generalized to

\[
L_{\alpha}(U_{\alpha}^{\text{eff}})P_{\alpha}(x,v,t) = \left( \mathbb{K}_{FP}(M_{\alpha}, \Gamma_{\alpha}) + \mathbb{K}_{BGK}^0 \right) P_{\alpha}(x,v,t)
\] (66)

where

\[
U_{\alpha}^{\text{eff}}(x,t) = U_{\alpha}(x,t) + \sum_{\beta} \int d\mathbf{y} U_{\alpha \beta}(x - \mathbf{y}) n_{\beta}(\mathbf{y},t) \quad n_{\beta}(\mathbf{y},t) = \int d\mathbf{v} P_{\beta}(\mathbf{y},\mathbf{v},t)
\] (67)

F)- We briefly sketch how to incorporate several chemical reactions schemes, beyond the BGK scheme (deterministic, stochastic, photoreactions, etc., see for example [162, 175]) in order to model molecular motors. We present two chemical reactions that can be approximated at the Kramers equation level, yielding the correct Smoluchowski-reactive equation.

For the nonlinear reaction

\[
A + B \xrightleftharpoons[k_-]{k_+} C + D
\] (68)

the kinetic equations are retrieved if we consider the BGK like scheme...
\[
K^A_{BGK} P_A(x, v, t) = -k_B n_B P_A + k_C n_D f_0(v, m_A, T)
\]
\[
K^B_{BGK} P_B(x, v, t) = -k_A n_P B + k_C n_D f_0(v, m_B, T)
\]
\[
K^C_{BGK} P_C(x, v, t) = -k_D n_P C + k_A n_B f_0(v, m_C, T)
\]
\[
K^D_{BGK} P_D(x, v, t) = -k_C n_D P + k_A n_B f_0(v, m_D, T)
\]

Finally, for the reaction cycle

\[
A_1 \xrightarrow{k_1} A_2 \xrightarrow{k_2} A_3 \xrightarrow{k_3} A_4 \cdots A_l \xrightarrow{k_l} A_1
\]

we reproduce the correct kinetics with the approximation

\[
K^\alpha_{BGK} P_\alpha(x, v, t) = -k_\alpha P_\alpha + k_{\alpha-1} f_0(\alpha)(v, m_\alpha, T)n_{\alpha-1} \quad n_0 = n_l \quad \alpha = 1, \ldots, l
\]

6: Concluding remarks

We have extended our previous work on charged Brownian particles [73, 75, 77], in order to obtain a consistent expansion scheme in powers of the collision time. We presented the complete hydrothermodynamical picture for charged Brownian particles in the Kramers equation scheme, considering the action of external magnetic, electric and mechanical fields, chemical transformations within the BGK scheme, and furthermore space dependent thermal fields (inhomogeneous media).

We developed a recursive method, in order to expand in powers of the collision time \(\tau\), the several moments of the solution of Kramers equation, enabling us to compute the governing equations for mass (charge), momentum (stream velocity) and energy (heat) flow. In the appropriate limits we retrieve previous results, and present novel formulations and results with immediate physical consequences.

Applications A, B and C (previous section) clearly indicates that the Brownian scheme cannot be modelled, in general and in earnest, by the local equilibrium approximation, no variational principle associated with entropy production is applicable, and hyperbolic extensions of Fourier heat conduction law must be considered even in lowest order. Therefore, variational principles relevant to the Brownian scheme, must go beyond entropy production considerations, and include among others, free energies, efficiency factors and power output as well [69, 70] and connected to nonequilibrium fluctuation and work relations [176]-[185].

In the following Applications items we briefly outline, from the formalism developed in this work, some novel schemes: D) the incorporation of magnetic field effects on the nonequilibrium state variables (including an application for carrier transport in inhomogeneous semiconductors); E) inclusion of interacting Brownian fluids via mean field approximation schemes, and F) inclusion of chemical reactions to Kramer’s approach to Brownian motion.

Our future work concentrates in variational principles associated to the Brownian motion, inclusion of chemical reactions and the magnetic field effects in hot carrier transport in semiconductors [186].
