Abstract

Granulomatous polyangiitis (GPA) is a small vessel vasculitis commonly affecting the upper and lower respiratory tracts and kidneys. About 90% of the cases are associated with ANCA, namely, PR3-ANCA and MPO-ANCA. Herein, we describe a patient of GPA who presented with anasarca, sensory neuropathy, recurrent upper airway congestion, epistaxis, and rapidly progressive glomerulonephritis. Granulomatous interstitial nephritis and necrotizing granulomatous inflammation of the nasal septum were found on biopsy of the kidney and nasal septum, respectively both of which are rare findings. PR3-ANCA and MPO-ANCA were negative. Fulfilling the ACR criteria, this case of GPA proves that biopsy is still the gold standard of diagnosis.

Keywords: ANCA, granulomatosis with polyangiitis, interstitial lung disease, interstitial nephritis, peripheral neuropathy

Introduction

Vasculitis is an inflammation of vascular walls resulting in organ damage. As per the Chapel Hill Consensus Conference classification, it is classified into large vessel vasculitis, medium vessel vasculitis, small vessel vasculitis, variable vessel vasculitis, single organ vasculitis, vasculitis associated with systemic disease, and vasculitis with probable etiology.¹,² The antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis includes ANCA against myeloperoxidase and proteinase-3 whereas ANCA negative vasculitis has ANCA that are undetectable by conventional methods or are of unknown specificity.³ The four criteria laid by the American College of Rheumatology (ACR) 1990 for the diagnosis of granulomatous polyangiitis (GPA) include nasal or oral inflammation, abnormal chest radiograph, abnormal urinary sediment, and granulomatous inflammation.³⁴ The presence of two or more of these four criteria yields a sensitivity of 88% and a specificity of 92%.⁵,⁶ Herein, we describe an unusual case of GPA presented with upper and lower respiratory tract involvement with granulomatous interstitial nephritis and peripheral neuropathy fulfilling the four criteria.⁴,⁵

Case Report

A 27-year-old male, a resident of northeast India, presented as an outpatient in the department of dermatology in January 2019. He was diagnosed as a case of Hansen's disease since 2013 and was on multidrug therapy (dapsone, rifampin, clofazimine) for the same. His treatment was stopped in September 2015 following which in November 2015 he developed skin lesions on the limbs with tingling and numbness. Hence, treatment was restarted and continued till January 2019 when he complained of tender erythematous skin nodules clinically diagnosed as...
erythema nodosum along with numbness of all the limbs. He also complained of nasal congestion. Slit-skin smear was negative for acid-fast bacilli (AFB). All routine investigations were normal [Table 1]. He was discharged on nortriptyline, gabapentin, and prednisolone in tapering doses.

However, after 3 months, he presented with anasarca, persisting nasal congestion, throat pain, numbness, and loss of sensation of both upper and lower limbs. He was transferred to the medicine department for further evaluation. His blood pressure on admission was 130/80 mmHg, with a heart rate of 110/min. He had a low-grade fever, pitting edema of both lower limbs, and generalized dry scaly plaques. There was no nerve thickening. On systemic examination, he had signs of peripheral neuropathy with impaired fine sensations in both lower limbs.

On detailed evaluation, he had nephritic-range proteinuria which subsequently progressed to nephrotic-range proteinuria suggesting glomerulonephritis with significant red blood cells on urine analysis [Tables 2 and 3]. He also had a clinical picture of chronic nasal septal inflammation. Thus a renal and nasal biopsy was carried out along with non-contrast imaging of the lung. The renal biopsy showed expansion of the interstitium with inflammatory infiltrates along with interstitial edema. There were a few large and small non-caseating granulomas with multinucleated giant cells in the interstitium [Figure 1a]. All the glomeruli were unremarkable. Immunofluorescence showed no immune complex deposits as IgG, IgA, IgM, C1q, and C3 were negative. Based on these findings, the renal biopsy was suggestive of granulomatosis interstitial nephritis. Nasal biopsy showed a necrotizing granulomatous lesion with evidence of leukocytoclastic [Figure 1b and 1c]. Non-contract computed tomography (CT) thorax showed ground-glass appearance in the lower zone of the lungs [Figure 2]. Thus the diagnosis of granulomatosis with polyangiitis was made with a Birmingham vasculitis activity score of 36 though his ANCA was negative.

During his hospital stay, he developed a catheter-related bloodstream infection resulting in worsening of renal function for which he received broad-spectrum antibiotics and responded. The glomerulonephritis picture persisted even on recovery from bacteremia along with constitutional symptoms. Hence, after the 7th day of antibiotic with low procalcitonin level, the patient was initiated on methylprednisolone pulse therapy and injection cyclophosphamide (cyclophosphamide-based regime 0.5 g/m² fortnightly for 3 to 6 months).[^6] His renal function test subsequently improved with proteinuria of 724 mg/24 h. He was continued on oral steroids and injection cyclophosphamide every fortnight for 6 months with BVAS of 13 from 25 on discharge. He received pneumococcal and influenza vaccinations and oral prophylaxis of trimethoprim-sulfamethoxazole. On follow-up, he was responding well to pulse therapy of injection cyclophosphamide with normal

---

**Table 1: Baseline investigations**

| Investigations       | Results          |
|----------------------|------------------|
| Hb 14 g %            | Total protein 6.4|
| Pt 180000            | Albumin 3.7      |
| TC 6100              | SGOT/SGPT 29/38  |
| Creatinine 0.9 mg/dL | Bilirubin 0.6    |
| Slit-skin smear      | Negative for AFB |

### Discussion

Our patient presented with ANCA negative GPA having upper, lower airway involvement, sensory neuropathy with rapidly progressive glomerulonephritis with nasal biopsy suggestive of the necrotizing granulomatous lesion with leukocytoclastic and renal biopsy suggestive of granulomatous interstitial nephritis. Though the diagnosis of small vessel vasculitis includes ANCA positivity either to PR3 or myeloperoxidase, this is one rare case where ANCA was negative with three organ involvement, which was upper airway, lungs, and kidneys. GPA is a disease with diverse manifestations involving the respiratory tract and kidneys with positive biopsy findings and ANCA being positive. The presence of granulomatous interstitial nephritis in GPA is rare. In a case report of 32 patients with granulomatous interstitial nephritis by Mignon et al., 28% were due to drugs, 16% were due to GPA, and 9% were attributed to sarcoidosis and tuberculosis. This paper is important to primary healthcare physicians because patients presenting with clinical manifestations suggesting more than one organ involvement mandates a thorough workup to rule out inflammatory disorders like vasculitis, connective tissue diseases, and immunological disorders.

### Conclusion

This case shows the rare presentations of GPA; firstly, the granulomatous interstitial nephritis on renal biopsy; secondly, nasal biopsy showed necrotizing granulomatous lesions; and thirdly, ANCA negativity despite the severity of the disease. Hence, the ACR criteria with a biopsy-proven granulomatous involvement are still the gold standard method of diagnosing the disease.
