Abstract. One of the value drivers in Industry 4.0 is asset utilization that has capability to remote monitoring and controlling the assets. Some of the problems on the production floor, especially in modern manufacturing areas such as machining process in the Flexible Manufacturing System (FMS), requires the condition of the cutting tools. This paper will discuss a model of cutting tools online monitoring system that operated in web based application. The model involves three sensors and a human machine interface to show the cutting tools condition. The sensors consist of temperature sensor, accelerometer, and electrical power consumption sensor; while in the experiment, the data of those sensors will be compared with the flank wear and crater wear on the cutting tools. The model shows that the data of temperatures, vibration and power consumption are collected by the sensors and sent by internet to the monitoring systems.

1. Introduction

The manufacturing enterprises in the Industrial 4.0 exploit the advantage of IoT (the Internet of Things), which related to the information technology to help solve industries problems. Baur et al. [1] stated that there are eight value drivers in Industry 4.0, which are resource/process, asset utilization, labour, inventory, quality, supply/demand match, time to market, service/after sales. Related to asset utilization, Industry 4.0 can provide data for predictive maintenance including remote monitoring and control. Gania et al. [2] explained that one of the solutions for Industry 4.0 is to utilize the facilities of Flexible Manufacturing System (FMS).

The cutting tools are the important tools in the FMS. Setiawan et al. [3] consider the cutting tools lifetime in production scheduling for the FMS. In the real situation, the cutting tools may broke before its lifetime. Therefore Setiawan et al. [4] developed production rescheduling in FMS. The research in Setiawan et al. [3] and [4] are the analytical modelling to get optimal solution. The implementation model requires a system that has capability to monitor the cutting tool condition.

The study of the cutting tools has been initiated by Taylor [5] that the cutting tool conditions are determined by the crater and flank wear. The cutting tool wear rate are exponential and determined the cutting tool lifetime. Chao et al. [6] used an improved...
neural network model to predict the life of the cutting tools. While Vagnorius et al. [7] explains that cutting tool conditions can be determined with several causes of wear and tear, internal stresses, grinding errors and the cutting tool installation. The reliability model that developed by Vagnorius et al. has been using the Weibull distribution function.

The wear and tear on the cutting tools will increase the cutting force and the energy consumption. Meanwhile the temperature is also increase, as well as the vibration. To monitor the cutting tool condition, Cus et al. [8] developed Adaptive Neuro - Fuzzy Inference System (ANFIS) to process the cutting force data from the dynamometer. While Huo et al. [9] monitor the cutting tool conditions by utilizing acoustic emission (AE) sensors. Kovac et al. [10] predicts the life of the cutting tools by using thermocouple. In the next study, Kovac et al. [11] improved the model by utilizing the dynamometer, acoustic emission (AE) sensor, three component accelerometer and CCD vision systems to monitor the cutting tool conditions.

The research proposed in this paper is to develop a model of Cutting Tool Condition Monitoring System (CTCMS) that supports the application of the concept of Industry 4.0. The development of CTMS began with a simple experiment of installing sensors of electrical energy consumption, temperature sensors and vibration sensors on manual (conventional) lathe before being implemented in the FMS. In general, the type of sensor used to capture temperature data is contactless temperature sensor (MLX-90614), while to capture vibration data using LIS-3DH accelerometer sensor. The electric energy consumption is measured by IC-ADE7758. The obtained data are transmitted over the internet to the database to be extracted to the cutting tools condition data. This paper also explains the type of data will be obtained from the sensor and how they are processed into the information condition of cutting tool. The data that has been processed can be seen by the production supervisor of the office by utilizing web facilities.

2. Cutting Tool Monitoring Hardware Configuration

Configuration of the sensor on the lathe is shown in Figure 1. The location of the temperature sensor and vibration sensor is located on a removable shank tool holder with its cutting tool. The tool holder is then mounted on the post tool on the lathe. While the electrical consumption sensor installed serially with a power source with the electrical motor on the lathe. These three types of sensors are connected to a microcomputer that can transmit data over the internet.

The research proposed in this paper is to develop a model of Cutting Tool Condition Monitoring System (CTCMS) that supports the application of the concept of Industry 4.0. The development of CTMS began with a simple experiment of installing sensors of electrical energy consumption, temperature sensors and vibration sensors on manual (conventional) lathe before being implemented in the FMS. In general, the type of sensor used to capture temperature data is contactless temperature sensor (MLX-90614), while to capture vibration data using LIS-3DH accelerometer sensor. The electric energy consumption is measured by IC-AD4858. The obtained data are transmitted over the internet to the database to be extracted to the cutting tools condition data. This paper also explains the type of data will be obtained from the sensor and how they are processed into the information condition of cutting tool. The data that has been processed can be seen by the production supervisor of the office by utilizing web facilities.

2. Cutting Tool Monitoring Hardware

Configuration of the sensor on the lathe is shown in Fig. 1. The location of the temperature sensor and vibration sensor is located on a removable shank tool holder with its cutting tool. The tool holder is then mounted on the post tool on the lathe. While the electrical consumption sensor installed serially with a power source with the electrical motor on the lathe. These three types of sensors are connected to a microcomputer that can transmit data over the internet.

Power Consumption
Sensor is connected with electrical motor

Accelerometer and thermometer on the tool post

Micro computer

Fig. 1. The configuration of sensors on conventional lathe.

The measurement for both crater wear and flank wear is still done manually, i.e. by using a magnifying glass and compared with a linear measuring instrument with the accuracy of 0.01mm. This wear measurement model is still in the refinement stage to increase the better accuracy up to 0.005mm.

3. Model Development

The Cutting Tool Condition Monitoring System model begins by observing the wear principle on the chisel, which reduces the cutting tools lifetime. As the cutting tools begin to be used, the crater wear and flank wear begin to occur. If a worn cutting tool is used for cutting, it will cause an increase in temperature and vibration on the cutting tools as well as increasing power consumption. In this research, it has not considered the machining process parameters, such as cutting speed, cutting feed and depth of cut for various types of the workpiece materials and the geometry and cutting tool materials.

3.1. Mathematical Model Formulation

The cutting tool condition model is presented with the reliability function of the cutting tool, which is denoted as follows:

\[ R(t) = \text{cutting tools reliability function at time } t. \]

\[ T(t) = \text{temperature at time } t. \]

\[ X(t) = \text{vibration at time } t. \]

\[ P(t) = \text{power consumption at time } t. \]

\[ \beta = \text{shape parameter in the Weibull distribution.} \]

\[ \theta = \text{scale parameter in the Weibull distribution.} \]

\[ MTTF = \text{mean time to failure of cutting tools} \]

\[ U = \text{cutting tool life time} \]

\[ V_c = \text{cutting speed} \]
$W_f = \text{flank wear on cutting tools}$

$W_c = \text{create wear on cutting tools}$

$$R(t) = f(T(t), X(t), P(t))$$

(1)

While the reliability function is related to the Weibull distribution, which is related to the shape and scale parameter [7].

$$R(t) = e^{-\left(\frac{t}{\theta}\right)^{\beta}}$$

(2)

$$MTTF = U = \theta \cdot \Gamma \left(1 + \frac{1}{\beta} \right)$$

(3)

Taylor [5] formulated the cutting tools life time ($U$):

$$v_c \cdot U^n = C$$

(4)

While, the reliability on cutting tool is related with flank and crater wear:

$$R(t) = f(W_f, W_c)$$

(5)

The concept of this research is to prepare the modelling of relation of the temperature, the vibration and the power consumption to the cutting tools life time, considering the wear on cutting the tools.

3.2 Object-Oriented Modelling Approach

The web application of Cutting Tool Condition Monitoring System is developed following the object-oriented modelling approach. There are seven classes in the Unified Modelling Language (UML) diagram which are machine tool class, power sensor class, accelerometer class (for the vibration sensor), cutting tool class, raw material class and the CTCMS class. Each classes have attributes that related to the CTCMS class as shown in the Figure 2.
There are five stages to complete the CTCMS hardware and the web application. The stage one is to test the prototype of CTCMS hardware and the web application. The objective in this stage is to transmit and present the data. The stage two is the algorithm development to build the relation of the temperature, vibration, power consumption data and the wear on the cutting tools. The stage three is building the database of the combination various raw materials and the cutting tools geometry and materials. The stage four is to enrich the database of the variation of the cutting parameters, which are cutting speed, feed and depth of cut. The stage five is refinement the CTCMS hardware and web application. As this paper is prepared, the research is in the stage one.

4. Exercise and Analysis of Stage One

The prototype of the CTCMS has been developed and tested on several exercises. The objective of the exercises is test the hardware capabilities to send and store the data in the database. Nevertheless, the data for the exercises are as follows: The cutting tool material is HSS with straight geometry as shown in Figure.3. The raw material is wood (non-metallic materials), rod shape which has 80 mm in diameter and 400mm long. The cutting speed is 75 m/min, feed 25 mm/min and 3 mm depth of cut. Since the wear on cutting tool is measured manually and limited accuracy, the wear rate is assumed constant and the maximum crater or flank wear is 0.01mm. The result of data acquisition from sensors is presented in Table.1. The units for wear is in mm, temperature in Celsius, vibration in mm²/second, and power in watt.
Fig. 3. The HSS Cutting tool.

Table 1. The data of wear, vibrations, power consumption and login time.

| No. | Wear | Temp | Vibration | Power | Log time |
|-----|------|------|-----------|-------|----------|

| 34  | 0.065 | 38.75 | -1.71 | 8.24 | -0.15 | 2053 | 56:27 |
| 35  | 0.067 | 38.59 | 0.15 | 10.94 | 9.29 | 2054 | 56:33 |
| 36  | 0.069 | 37.45 | 0.13 | 9.25 | 0.34 | 2054 | 56:40 |
| 37  | 0.071 | 36.81 | 0.06 | 9.2 | 0.27 | 2054 | 56:45 |
| 38  | 0.073 | 36.39 | 0.06 | 9.2 | 0.04 | 2054 | 56:50 |
| 39  | 0.075 | 35.99 | 0.08 | 9.29 | 0.25 | 2054 | 56:53 |
The data is then processed to obtain the relationship between the relationship of the cutting tool reliability function to the temperature, vibration and consumption data, as compiled in formula (1). Table 2 shows the regression statistics of the data to develop the multiple linear regression equation in 52 observations. Correlation coefficient (Multiple R) 0.976 indicates strong linear association between dependent variable (wear) and independent variables (temperature, vibration, and power data). Coefficient determination (R square) indicates 95.26% of total variation of wear explained by the independent variables.

Table 2. The regression statistics.

| Regression Statistics |  
|-----------------------|  
| Multiple R            | 0.9760  
| R Square              | 0.9526  
| Observations          | 52      |

Table 3 show result of the analysis of variance (ANOVA). The total sum of square (0.0412 + 0.002 = 0.0433) is the squared error that would occur. Using the values of independent variables reduces this error by 95.15% or (0.0412 / 0.0433). This reduction is deemed statistically significant with an F ratio of 185.15 and a significance level of 0.00.

Table 3. The analysis of variance.

|          | df | SS   |  | F   | Sig. F |
|----------|----|------|---|-----|--------|
| Reg.     | 5  | 0.0412 | 185.15 | 0.00 |
| Residu.  | 46 | 0.0020 |     |     |        |
| Total    | 51 | 0.0433 |     |     |        |

Table 4 is the coefficients for multiple linear regression. The value of -0.001045 is the regression coefficient for temperature. The predicted value for each observation is the intercept (-11.531632) plus the regression coefficient times its value of each independent variables.
Table 4. The regression statistics.

| Coefficients | Standard Error |
|--------------|----------------|
| Intercept    | -11,531632     |
|              | 0,4386         |
| Temp.        | -0,001045      |
|              | 0,0002         |
| X            | -0,000131      |
|              | 0,0003         |
| Y            | 0,000419       |
|              | 0,0004         |
| Z            | -0,000402      |
|              | 0,0003         |
| Power        | 0,005671       |
|              | 0,0002         |

Therefore the multiple linear regression is as follows:

\[
R(t) = (-0.001045 \times T(t)) - (0.000131 \times X(t)) + (0.000419 \times Y(t)) - (0.000402 \times Z(t)) + 0.005671 \times P(t) - 11.531632 \tag{6}
\]

The standard error of temperature is 0,0002 denoting that 95% confidence interval for temperature would be -0,001045 ± (1.96 x 0,0002) or ranging from a low of -0,000596 to a high of -0,001491.

The temperature, vibration (acceleration in X, Y, Z direction) and power data are inputted to the formula (6), then the wear on each time is plotted in the graphics as shown in Figure 4.

Fig. 4. The wear of cutting tool at time.

Then, the wear of cutting tool at time distribution identified using Minitab 17. Figure 5 show p-value < 0.001. It indicates cutting tool wear is fit into Weibull distribution with α = 5%. This distribution has shape parameter 1.85683 and scale parameter 0.05736.
Table 4.
The regression statistics.

| Coefficients | Standard Error |
|---------------|----------------|
| Intercept     | -11,5316       |
| Temp.         | -0,001045      |
| X             | -0,000136      |
| Y             | 0,000419       |
| Z             | -0,000402      |
| Power         | 0,005671       |

Therefore, the multiple linear regression is as follows:

\[ R(t) = e^{-0.001045 \times T(t)} - 0.000136 \times X(t) + 0.000419 \times Y(t) - 0.000402 \times Z(t) + 11,531632 \] (6)

The standard error of temperature is 0.0002, denoting that 95% confidence interval for temperature would be -0.001045 ± (1.96 x 0.0002) or ranging from a low of -0.000596 to a high of -0.001491.

Fig. 4. The wear of cutting tool at time.

Then, the wear of cutting tool at time distribution identified using Minitab 17. Figure 5 show p-value < 0.001. It indicates cutting tool wear is fit into Weibull distribution with \( \alpha = 5\% \). This distribution has shape parameter 1.85683 and scale parameter 0.05736.

Fig. 5. Probability Plot of Wear.

Function of the cutting tool wear in Weibull distribution is as follows:

\[ R(t) = e^{-1.85683(0.05736) t} \]

5. Conclusion

Refers to the results of analysis, implementation, and testing of cutting tool on the conventional lathe, this paper can conclude that the application manages to retrieve data from temperature sensors, vibrating sensors, and electrical sensors attached to cutting tool on lathe by the CTCMS prototype in stage one.

This research is supported and funded by Penelitian Strategis Nasional Tahun Anggaran 2018 focus on Teknologi Informasi dan Komunikasi by Kementrian Riset, Teknologi dan Pendidikan Tinggi and Kopertis Wilayah IV Jawa Barat- Banten.
