Abstract
Purpose: The aim of the present study was to investigate the impact of total soy saponins (TS) on the myocardial antioxidant capacity in rats exercised to exhaustion.
Methods: The one-time exhausted treadmill model was used. All rats were divided into 4 groups: the control group, the TS group, the exhausted group, and the TS exhausted group. The TS and TS exhausted groups were fed TS at a dosage of 20 mg/kg body weight, once a day, for 2 weeks. The exhausted group was given a placebo, and the control group was not given any treatment. The treadmill speed was set at 30 m/min, and the rats (exhausted and TS exhausted groups) were trained at this speed until exhausted. The rats were decapitated and anatomicized immediately after exhausted. A 10% homogenate of the myocardial tissue was prepared.
Results: TS significantly increased the exercise time by 20.62% (p < 0.05). As compared with the control group, the enzyme activities for catalase (CAT), glutathione peroxidase (GSH-Px), and glutathione reductase (GR) were significantly enhanced in the TS group (p < 0.01); GR and GSH-Px activity was significantly enhanced in the TS exhausted group (p < 0.01); malondialdehyde (MDA) levels were significantly decreased in the TS exhausted group (p < 0.05). As compared with the exhausted group, the GSH-Px activity was significantly enhanced in the TS exhausted group (p < 0.01); CAT, GSH-Px, and GR activities were significantly enhanced in the TS group (p < 0.01). As compared with the TS group, the CAT and GR activity in the TS exhausted group was significantly decreased (p < 0.01).
Conclusion: TS can improve the exercised rats’ antioxidant activity in their cardiac muscle to varying degrees, decrease MDA and serum AST and LDH levels, increase the exercise time, and delay the occurrence of sports fatigue.

Keywords: Antioxidant; Cardiac tissue; Exercise exhaustive rat; Total soy saponins

1. Introduction
Total soy saponins (TS) are a subset of pentacyclic triterpenoid glycosides with a variety of biological activities. According to the different sapogens, TS can be divided into 4 groups: A group, B group, E group, and 2,3-dihydro-2,5-dihydroxy-6-methyl-4H-pyran-4-one (DDMP) group (Figs. 1 and 2). The A group can be divided into Aa–Ah; the B group can be divided into Ba, Bb, Bc, Bb', and Bc'; the E group can be divided into Bd and Be; and the DDMP group can be divided into αg, βg, βa, γg, and γa subgroups.

There were 2 free radical (FR) defense systems in the human body. One type is an enzymatic defense system such as superoxide dismutase (SOD), glutathione peroxidase (GSH-Px), catalase (CAT), and glutathione reductase (GR). The other is a non-enzymatic defense system such as vitamin C, vitamin E, and glutathione (GSH). Typically, the body keeps a dynamic balance between the generation and removal of FR. However, under the condition of exhausted exercise, FR in the body increases significantly. When the level of lipid peroxidation exceeds the body’s antioxidant capacity, this results in the occurrence of oxidative stress, directly causes biofilm injuries,
the degeneration of intracellular proteins, and leads to cell death, apoptosis, tissue damage, and disease.\textsuperscript{1}

TS have a variety of biological activities, such as antioxidant\textsuperscript{2} and immune-enhancing activity.\textsuperscript{3,4} They can also improve the rats’ macrophage phagocytic capacity\textsuperscript{5} and humoral and cellular immunity.\textsuperscript{5} By inhibiting the activity of $\alpha$-glucosidase\textsuperscript{6} and $\alpha$-amylase,\textsuperscript{7} TS significantly reduced the level of blood sugar in diabetic rats and significantly improved glucose tolerance in both diabetic and healthy rats.\textsuperscript{8} TS also have significant effects for anti-aging\textsuperscript{9} and the inhibition of tumor cell DNA,\textsuperscript{10} Herpes simplex virus (HSV-1), human cytomegalovirus (HCMV), polio virus, influenza virus, measles virus, mumps virus, and Coxsackie virus.\textsuperscript{11–14} Further anti-aging studies on human embryonic lung diploid fibroblasts \textit{in vitro} confirmed that cells treated with TS can grow to 80 generations, whereas the longest survival time of the control group was only 51 generations.\textsuperscript{15} TS also have significant anti-lipid peroxidation activity on plasma lipoproteins.\textsuperscript{16} They can prevent low-density lipoprotein (LDL) from oxidizing and decrease their susceptibility to oxidation, thus hindering the conversion of LDL to oxidized LDL, which is the most important risk factor for atherosclerosis. TS protected not only the heart but also the vascular smooth muscle. TS can significantly reduce the generation of lipid peroxides, protect endothelial integrity, and maintain normal cardiovascular function.

2. Methods

2.1. Experimental animals

Thirty-two Sprague-Dawley (SD) healthy male rats were used (weight 190–210 g, 2 months old) and were provided by the Experimental Animal Center of the Medical School, Xi’an Jiaotong University (animal certificate number: Shannxi Medical Animal No. 08-005). The study was performed according to the international, national, and institutional rules considering animal experiments, clinical studies and biodiversity rights, and had been approved by Xijing Hospital Ethic Committee in Fourth Military Medical University.

2.2. Main instruments

A 721B spectrophotometer (Shanghai Jingke; Shanghai Precision & Scientific Instrument Co., Ltd., Shanghai, China), a 752B spectrophotometer (Shanghai Jingke), a Hitachi 7060 automatic biochemical analyzer (Hitachi Corporation of Japan, Tokyo, Japan), LabStar 2.5 (Beijing Zhifang Technology Development Co. Ltd., Beijing, China), a TGL-16G refrigerated centrifuge (Flying Pigeon; Shanghai Anting Scientific Instrument Factory, Shanghai, China), a DK-98-1A water bath (Taisite; Tianjin City Taisite Instrument Co., Ltd., Tianjin, China), and a DSPT-202 treadmill (Duanshi; Shanghai Xinruan Information Technology Co., Ltd., Hangzhou, China) were used.

2.3. Experimental procedure

2.3.1. Animal groups

All rats were randomly divided into 4 groups: control group, TS group, exhausted group, and TS exhausted group. Eight rats from each group were fed in divided cages. The temperature varied from 22°C to 28°C, the relative humidity was 45%–65%, the cages were illuminated by natural light, the ambient noise was no higher than 45 dB, and all rats had free access to water and basic rodent chow.

2.3.2. Supplement dosing

TS were provided by North China Pharmaceutical Co., Ltd. (Shijiazhuang, China) with a purity of 90% and 10% ash. The rats were started on TS gavage after 3 days of adaptation to the environment. Each rat in the supplement group (TS group and TS exhausted group) was fed a 2 mL aliquot of TS dissolved in normal saline at a fixed time 9:00–9:30 a.m., once a day, for 2 weeks. All rats in the supplement groups were fed TS at a
Table 1: Impact of total soy saponins (TS) on the exhaustion time in exhausted rats (n = 8 in each group, mean ± SD).

| Indices                      | Exhausted group | TS exhausted group | Growth rate |
|------------------------------|-----------------|--------------------|-------------|
| Velocity (m/min)             | 30              | 30                 | 0           |
| Average exercise time (min)  | 86 ± 12         | 103 ± 19           | 20.62%      |

Note: By t test, as compared with the exhausted group, the treadmill exhaustion time increased significantly in the TS exhausted group (p < 0.05, Cohen’s d = 1.07).

dosage of 20 mg/kg body weight. During the supplement gavage, the rats were weighed every 3 days, and the dosage was adjusted according to the body weight. The exhausted group was fed the same volume of normal saline vehicle. The control group received no treatments.

2.3.3. Exhaustive exercise protocol

An acute exhaustive exercise protocol was applied. The rats were not given any prior training. The exhausted and TS exhausted group rats underwent the acute exhaustive exercise on the treadmill only before dissection. The treadmill was horizontal and gradually increased to the predetermined exercise intensity (30 m/min) within 3 min. The treadmill speed was set at 10 m/min for the first minute, 20 m/min for the second minute, and 30 m/min for the third minute. The exercise time and exercise distances of each rat were then recorded. We judged whether the rats exercised to exhaustion according to the following criteria: the rats could not maintain a predetermined movement speed, squatted against the back wall of the treadmill lane on its buttocks, and both the current stimulus and the brush driving could not force the rats to continue exercising. The exhausted behavior was characterized by shortness of breath, mental fatigue, and a prone nutation.

2.3.4. Dissection and index test

The rats were anesthetized with ether after exhaustion and killed by decapitation. The blood was collected, and the serum was separated after blood coagulation. The heart was removed immediately, and the blood was washed away with 4°C normal saline and then placed in a clean culture dish marked according to each group. The weight of the myocardial tissue was measured, and the heart was ground in 4°C normal saline. Myocardial tissue homogenates of 10% mass concentration were prepared and the supernatant was separated after centrifugation (7.99 × g, 5 min). Finally, the antioxidant indicators were assayed accordingly.

2.4. Methods of testing

The antioxidant indicators were tested with reagent kits provided by Nanjing Jiancheng Bioengineering Institute (Nanjing, China). SOD was tested by the xanthine oxidase method; malondialdehyde (MDA) was tested by the thiobarbituric method (TBA method); CAT was tested by the ultraviolet spectroscopy method; GSH-Px, GR, and GSH were tested by the dithiobis nitrobenzoic acid method; total antioxidant capacity (T-AOC) was tested by a spectrophotometry method. The serum aspartate aminotransferase (AST) lactate dehydrogenase (LDH) levels were tested by an automatic biochemistry analyzer (Hitachi 7060).

2.5. Data processing

The experimental data were processed with statistical software SigmaStat (Version 3.5; SYSTAT Software Inc., San Jose, CA, USA), and the results were shown as means ± SD. A p < 0.05 or p < 0.01 was considered statistically significant after a 1-way analysis of variance Student–Newman–Keuls test (S-N-K test). The exhaustive time was processed by a t test, and the results of the t test were measured by Cohen’s d value.

3. Results

3.1. The exhaustion time of the rats

3.1.1. Antioxidant and serum enzyme indices

As shown in Table 1, TS can significantly increase exhaustion time of the rats by 20.62% (p < 0.05, Cohen’s d = 1.07). According to the Cohen standards, the t test has a small effect size, medium effect size, and large effect size when Cohen’s d value = 0.2, 0.5, and >0.8. The Cohen’s d value of present t test was 1.07 > 0.8, which indicated that the present t test was trustworthy.

Table 2 shows that TS can improve rats’ antioxidant capacity in their cardiac muscle to varying degrees.

As compared with the control group, the enzyme activities of CAT, GSH-Px, and GR were all significantly enhanced in the TS group (p < 0.01); GR and GSH-Px activity was enhanced significantly (p < 0.01), and the MDA levels decreased signifi-

| T-AOC (U/mg prot)        | 2.32 ± 0.65   | 2.60 ± 1.01   | 1.78 ± 0.47     | 2.56 ± 0.86      |

Note: By S-N-K test of a 1-way ANOVA: ‘p < 0.05, ‘p < 0.01, compared with the control group; ‘p < 0.01, compared with the exhausted group; ‘p < 0.01, compared with the TS group.

Abbreviations: CAT = catalase; GR = glutathione reductase; GSH = reduced glutathione; GSH-Px = glutathione peroxidase; MDA = malondialdehyde; SOD = superoxide dismutase; T-AOC = total antioxidant capacity; TS = total soy saponins.
As compared with the control group, the CAT, GSH-Px, and GR activities increased significantly in the TS group, and SOD, GSH, and T-AOC showed a tendency to increase. This indicated that, under the TS intervention, the antioxidant compensatory mechanism of the body was reinforced, and thus the antioxidant enzymes activity increased and MDA levels decreased.

As compared with the control group, the CAT, GSH-Px, and GR activities increased significantly in the TS group, and SOD, GSH, and T-AOC showed a tendency to increase, whereas the MDA levels showed a tendency to decrease. This indicated that, in the resting state, TS can improve the antioxidant capacity of the rats’ myocardial muscle. The antioxidant effect of TS may be related to its chemical structure. The TS parent nuclear structure, which was rich in phenolic hydroxyls, can combine with FR and form a stable semiquinone and hence break the chain reaction of FR and directly clear FR. It has been reported that the TS monomer AI can significantly inhibit the activities of myocardial calcium channels T, L, and B, reduce its opening rate and time, alleviate the cell damage caused by calcium overload, and significantly attenuate FR levels induced by xanthine–xanthine oxidase.\(^{19}\) Sun et al.\(^{20}\) reported that TS also has a strong total antioxidant capacity and an anti-active oxygen capacity in vitro. It can inhibit lipid peroxidation in liver tissue and alleviate the swelling of liver mitochondria,\(^{20}\) inhibit erythrocyte membrane lipid peroxidation and reduce the hemolysis of red blood cells.\(^{21}\)

During exhausted exercise, the body’s oxygen uptake increased substantially, of which approximately 2% is converted into FR.\(^{22}\) Therefore, during exhausted exercise, FR and especially oxygen FR levels increased significantly; this constituted one of the major factors of body injury and prompted the occurrence of exercise fatigue. Researchers have shown that exhausted exercise can weaken heart contractility, which can probably recover by 24 h after exercise.\(^{23}\) It was also shown that the recovery process was significantly correlated to the myocardial metabolism of FR.\(^{17}\) FR can cause an excitation–contraction coupling disorder by damaging the functions of the endoplasmic reticulum, which resulted in systolic dysfunction and contractility decline. FR also caused calcium overload by influencing intracellular calcium ion transport in myocardial cells, and thus the calcium overload also contributed to the decline in myocardial contractility.\(^{17}\) Other studies have also shown that myocardial contractility was negatively correlated to the rise of myocardial intracellular Ca\(^{2+}\).\(^{17}\) FR attack biofilms containing a large amount of unsaturated fatty acids, caused biofilm lipid peroxidation and membrane potential instability. Membrane potential abnormalities can in turn affect the action potential, which led to systolic dysfunction.\(^{24}\)

### Table 3

| Indices          | Control group | TS group       | Exhausted group | TS exhausted group |
|------------------|---------------|----------------|-----------------|--------------------|
| AST (U/mL)       | 189.67 ± 26.01| 165.67 ± 17.51 | 374.50 ± 271.77\(^{ab}\) | 329.33 ± 15.67     |
| LDH (U/L)        | 1345.83 ± 86.61| 1212.83 ± 97.01| 1512.00 ± 273.42\(^{a}\) | 1409.17 ± 237.10   |

Note: By S-N-K test of a 1-way ANOVA: \(^{a}\)p < 0.05, compared with the control group; \(^{b}\)p < 0.05, compared with the TS group.

The workability of the cardiac muscle was an important factor in limiting the exercise capabilities of these rats. Under the condition of exhausted exercise, the cardiac muscle was probably injured by ischemia–reperfusion, calcium overload, myocardial stunning, and FR.\(^{17}\) These factors can reinforce each other and create a vicious circle, and finally result in a weakness of heart contractility and increase the permeability of the rat myocardium cell membrane. The present results showed that TS can decrease the rats’ serum AST and LDH levels in both the TS and exhausted groups. Since serum AST and LDH are typical markers of myocardial damage, this result indicated that TS can significantly protect the myocardial muscle in both the resting state and working state.

As compared with the control group, the experimental data showed that MDA tended to decrease, whereas SOD, CAT, and GR activities tended to increase in the exhausted group. This result can be explained as follows: under the condition of exhausted exercise, the rats’ FR metabolism increased and stimulated to the emergence of a compensatory reaction to eliminate these FR. As a result, the antioxidant enzyme activity increased, and this led to the rise in the FR elimination rate and followed by the reduction in MDA formation. This was due to the body’s self-regulation via negative feedback, and probably was one of the reasons why exercise shows an anti-aging effect.\(^{18}\)

As compared with the exhausted group, GSH-Px activity was significantly enhanced in the TS exhausted group (p < 0.01). The CAT, GSH-Px, and GR activities were all significantly enhanced in the TS group (p < 0.01). SOD, CAT, GR, GSH, and T-AOC activities showed a tendency to increase (whereas MDA decreased) in the TS exhausted group, but again this was not statistically significant.

As compared with the TS group, the CAT and GR activity in the TS exhausted group was significantly decreased (p < 0.01). The SOD and GSH-Px activities showed a tendency to increase, but a tendency to decrease was observed for MDA, GSH, and T-AOC in the TS exhausted group (not statistically significant).

Table 3 shows that TS can decrease rats’ serum AST and LDH levels to varying degrees. As compared with the control and TS groups, the serum AST levels were significantly increased in the exhausted group (p < 0.05). As compared with the TS group, the serum LDH levels were increased in the exhausted group (p < 0.05).

### 4. Discussion

The workability of the cardiac muscle was an important factor in limiting the exercise capabilities of these rats. Under the condition of exhausted exercise, the cardiac muscle was probably injured by ischemia–reperfusion, calcium overload, myocardial stunning, and FR. These factors can reinforce each other and create a vicious circle, and finally result in a weakness of heart contractility and increase the permeability of the rat myocardium cell membrane. The present results showed that TS can decrease the rats’ serum AST and LDH levels in both the TS and TS exhausted groups. Since serum AST and LDH are typical markers of myocardial damage, this result indicated that TS can significantly protect the myocardial muscle in both the resting state and working state.

As compared with the control group, the experimental data showed that MDA tended to decrease, whereas SOD, CAT, and GR activities tended to increase in the exhausted group. This result can be explained as follows: under the condition of exhausted exercise, the rats’ FR metabolism increased and stimulated to the emergence of a compensatory reaction to eliminate these FR. As a result, the antioxidant enzyme activity increased, and this led to the rise in the FR elimination rate and followed by the reduction in MDA formation. This was due to the body’s self-regulation via negative feedback, and probably was one of the reasons why exercise shows an anti-aging effect.\(^{18}\)

As compared with the control group, the CAT, GSH-Px, and GR activities increased significantly in the TS group, SOD, CAT, GR, GSH, and T-AOC also showed a tendency to increase. This indicated that, under the TS intervention, the antioxidant compensatory mechanism of the body was reinforced, and thus the antioxidant enzymes activity increased and MDA levels decreased.

As compared with the control group, the CAT, GSH-Px, and GR activities increased significantly in the TS group, and SOD, GSH, and T-AOC showed a tendency to increase, whereas the MDA levels showed a tendency to decrease. This indicated that, in the resting state, TS can improve the antioxidant capacity of the rats’ myocardial muscle. The antioxidant effect of TS may be related to its chemical structure. The TS parent nuclear structure, which was rich in phenolic hydroxyls, can combine with FR and form a stable semiquinone and hence break the chain reaction of FR and directly clear FR. It has been reported that the TS monomer AI can significantly inhibit the activities of myocardial calcium channels T, L, and B, reduce its opening rate and time, alleviate the cell damage caused by calcium overload, and significantly attenuate FR levels induced by xanthine–xanthine oxidase.\(^{19}\) Sun et al.\(^{20}\) reported that TS also has a strong total antioxidant capacity and an anti-active oxygen capacity in vitro. It can inhibit lipid peroxidation in liver tissue and alleviate the swelling of liver mitochondria,\(^{20}\) inhibit erythrocyte membrane lipid peroxidation and reduce the hemolysis of red blood cells.\(^{21}\)

During exhausted exercise, the body’s oxygen uptake increased substantially, of which approximately 2% is converted into FR.\(^{22}\) Therefore, during exhausted exercise, FR and especially oxygen FR levels increased significantly; this constituted one of the major factors of body injury and prompted the occurrence of exercise fatigue. Researchers have shown that exhausted exercise can weaken heart contractility, which can probably recover by 24 h after exercise.\(^{23}\) It was also shown that the recovery process was significantly correlated to the myocardial metabolism of FR.\(^{17}\) FR can cause an excitation–contraction coupling disorder by damaging the functions of the endoplasmic reticulum, which resulted in systolic dysfunction and contractility decline. FR also caused calcium overload by influencing intracellular calcium ion transport in myocardial cells, and thus the calcium overload also contributed to the decline in myocardial contractility.\(^{17}\) Other studies have also shown that myocardial contractility was negatively correlated to the rise of myocardial intracellular Ca\(^{2+}\).\(^{17}\) FR attack biofilms containing a large amount of unsaturated fatty acids, caused biofilm lipid peroxidation and membrane potential instability. Membrane potential abnormalities can in turn affect the action potential, which led to systolic dysfunction.\(^{24}\)
Along with myocardial ischemia–reperfusion injury, FR can increase in various ways such as via mitochondrial electronic leakage, xanthine oxidase in vascular endothelial cells, neutrophil respiratory bursts, and catecholamine oxidation. These mechanisms can lead to increased fluidity and permeability of the myocardial cell biofilm and subcellular organelles, and therefore destroy the integrity and functions of the cell. Myocardial ischemia–reperfusion injury also damages the arterial endothelium. As a result, it interferes with prostaglandin I$_2$ (PGI$_2$) synthesis, which occurs mainly in the coronary vascular endothelial cells, and platelets adhered to the endothelial collagen tissue, leading to a further release of vasoconstrictors, predominately thromboxane A$_2$ (TXA$_2$). TXA$_2$ can be available as a Ca$^{2+}$ carrier and directly promotes Ca$^{2+}$ influx and Ca$^{2+}$ release from the dense tubular system, thereby promoting platelet aggregation and local vasoconstriction, and thus increasing endothelium injury. Therefore, the imbalance between TXA$_2$ and PGI$_2$ can be one of the main causes of myocardial ischemia and myocardial necrosis, and this further affected cardiac contractility. The present study also showed that the serum AST and LDH levels increased after exhausted exercise, which indicated that the myocardial cells were injured and supported the hypothesis above.

SOD, CAT, and GSH-Px are common antioxidant enzymes which can eliminate FR and reduce their hazards. Under normal physiological conditions and an appropriate exercise load, the antioxidant enzymes system of the body, by way of their respective roles, keep a dynamic balance between FR generation and elimination. However, under the condition of exhaustive exercise, the generation rate of FR was far greater than the body’s ability to clear, and the balance was broken, which resulted in FR accumulation in the body. This in turn caused lipid peroxidation, then caused lipid peroxidation injury, DNA breakage, protein denaturation, and eventually led to sports fatigue. The interaction between the FR and the body was a negative feedback process: exercise intensity $\uparrow$ $\rightarrow$ FR level $\uparrow$ $\rightarrow$ body compensatory reaction $\uparrow$ $\rightarrow$ antioxidant enzyme activity $\uparrow$ $\rightarrow$ FR level $\downarrow$. Although the FR levels decreased finally, the body had already been injured by the FR before they were cleared. This inference was consistent with the present experimental data.

5. Conclusion

TS can significantly improve the antioxidant capacity of rat myocardial tissue, decrease MDA level and serum AST and LDH levels, protect myocardial muscle, enhance its T-AOC, attenuate FR damage to the myocardial cells and delay sports fatigue. Therefore, this protective effect on myocardial muscle may be one of mechanisms whereby TS can improve the rats’ exercise capability.
