INTRODUCTION

Malformations of cortical development (MCD) are a series of disrupted cerebral cortex formation disorders caused by multiple etiologies, including genetic, metabolic, vascular, and other factors (Severino et al., 2020). MCD usually occur in early childhood or early adulthood (Raybaud and Widjaja, 2011; Barkovich et al., 2012). It is characterized by developmental delays, intellectual disability, epilepsy, and even cerebral palsy. Occipital cortical malformation (OCCM; MIM: 614115) is a form of MCD characterized by polymicrogyria and pachygyria limited to the occipital lobe. Besides, the seizures, developmental, and cognitive delays can also be observed in affected individuals (Zambonin et al., 2018). A recent study found that impaired visual function was another clinical feature of OCCM due to compromised cortical architecture (Urgen et al., 2019). In 2011, Barak et al. applied whole-exome capture and sequencing technology to identify the recessive or complex heterozygous variants of the gamma-3 chain isoform of laminin (LAMC3) caused OCCM.
24 h, HEK 293T cells were transfected with 2.5 µg LAMC3-WT or variant (c.470G > A) plasmid DNA through Lipofectamine 3000 transfection reagent (Invitrogen). 36 h later, the cells were used for immunofluorescence and western blotting.

**Western Blotting**

The concentration of protein samples was determined using a BCA kit. Protein samples were diluted in 5X SDS-PAGE and boiled at 100°C for 10 min. 30 µg of protein sample was resolved by 8% SDS polyacrylamide gels. After being transferred to polyvinylidene fluoride membrane, the blots were incubated at 4°C for 12 h with the anti-GFP antibody (1:1000, Cell Signal Technology) and α-tubulin primary antibody (1:1000, Cell Signaling Technology). Finally, after incubation with secondary antibodies (1:5000, Beyotime), blots were analyzed by Kodak Digital Science1D software (East-man Kodak Co., New Haven, CT, United States).

**Immunofluorescence**

After transfection, PBS containing 4% paraformaldehyde was used to fix the cells for 30 min. Cells were blocked using a blocking solution, containing 0.3% Triton X-100 and 5% bovine serum albumin (BSA) in PBS for 30 min. DAPI (1:10,000, Cell Signal technology) was then applied for 5 min to stain nucleic acid staining. Finally, A Zeiss 710 confocal microscope was used for image collection.

**Minigene Reporter Assay**

BDGP: Splice Site Prediction by Neural Network, NetGene2 Sever and HSF: Human Splicing Finder Version 3.1 were used to evaluate the effects of variants on splice sites. PCR amplified the LAMC3 exons relevant to 1 novel splicing variant (c.4030 + 1G > A) along with flanking intronic sequences from patients P3672 with gDNA. The PCR products of c.4030 + 1G > A were cloned into the pcDNA3.1 vector and the pcMINI vector. Then the minigenes were transfected into HeLa cells and HEK 293T cells, respectively. The RNAiso Plus kit (Takara, Japan) was used for total RNA extraction, followed by RT-PCR using the PrimeScript RT reagent kit (Takara, Japan) to generate related cDNA. Electrophoresis on 2% agarose gels and Sanger sequencing were used for splicing pattern analysis.

**Bioinformatic Analysis**

The signal peptide sequence of LAMC3 was predicted by SignalP-5.0. The Search Tool for the Retrieval of Interacting Genes database (STRING) online database database was applied to predict genes potentially associated with LAMC3. Protein-protein interaction network (PPI) network and functional enrichment analysis including the cellular component, biological process, molecular function, and KEGG were exported as tables. Sangerbox and Cytoscape software were used to construct

**Materials and Methods**

**Genetic Analysis**

The genomic DNA of the proband and her parents were extracted using a standardized phenol/chloroform extraction method. Whole exome sequencing was performed as previously described (Zhu et al., 2019). Sanger sequencings was applied to validate variants of the LAMC3 gene in the proband and her parents. One thousand unaffected individuals of matched geographic ancestry were used as normal controls.

**Cell Culture**

HEK 293T cells were cultured in Dulbecco’s Modified Eagle Medium (DMEM) containing 10% fetal bovine serum (FBS) and 1% penicillin/streptomycin (PS) at 37°C with 5% CO2 and 95% O2. LAMC3 wild-type (LAMC3-WT) or variant (c.470G > A) plasmid, synthesized by Gene Create (Wuhan, China), with spliced GFP labels on the N-terminal. Before transfection, cells were plated at 150,000 cells per well in 6-well culture dishes. After 24 h, HEK 293T cells were transfected with 2.5 µg LAMC3-WT or variant (c.470G > A) plasmid DNA through Lipofectamine 3000 transfection reagent (Invitrogen). 36 h later, the cells were used for immunofluorescence and western blotting.

Western Blotting

The concentration of protein samples was determined using a BCA kit. Protein samples were diluted in 5X SDS-PAGE and boiled at 100°C for 10 min. 30 µg of protein sample was resolved by 8% SDS polyacrylamide gels. After being transferred to polyvinylidene fluoride membrane, the blots were incubated at 4°C for 12 h with the anti-GFP antibody (1:1000, Cell Signal Technology) and α-tubulin primary antibody (1:1000, Cell Signaling Technology). Finally, after incubation with secondary antibodies (1:5000, Beyotime), blots were analyzed by Kodak Digital Science1D software (East-man Kodak Co., New Haven, CT, United States).

Immunofluorescence

After transfection, PBS containing 4% paraformaldehyde was used to fix the cells for 30 min. Cells were blocked using a blocking solution, containing 0.3% Triton X-100 and 5% bovine serum albumin (BSA) in PBS for 30 min. DAPI (1:10,000, Cell Signal technology) was then applied for 5 min to stain nucleic acid staining. Finally, A Zeiss 710 confocal microscope was used for image collection.

Minigene Reporter Assay

BDGP: Splice Site Prediction by Neural Network, NetGene2 Sever and HSF: Human Splicing Finder Version 3.1 were used to evaluate the effects of variants on splice sites. PCR amplified the LAMC3 exons relevant to 1 novel splicing variant (c.4030 + 1G > A) along with flanking intronic sequences from patients P3672 with gDNA. The PCR products of c.4030 + 1G > A were cloned into the pcDNA3.1 vector and the pcMINI vector. Then the minigenes were transfected into HeLa cells and HEK 293T cells, respectively. Electrophoresis on 2% agarose gels and Sanger sequencing were used for splicing pattern analysis.

Bioinformatic Analysis

The signal peptide sequence of LAMC3 was predicted by SignalP-5.0. The Search Tool for the Retrieval of Interacting Genes database (STRING) online database database was applied to predict genes potentially associated with LAMC3. Protein-protein interaction network (PPI) network and functional enrichment analysis including the cellular component, biological process, molecular function, and KEGG were exported as tables. Sangerbox and Cytoscape software were used to construct
the visualized PPI network diagram and functional enrichment analysis bubble diagram, respectively.

**Ethics**

According to the Declaration of Helsinki principles, this study was approved by the Ethics Committee of the Ruijin Hospital affiliated with Shanghai Jiao Tong University School of Medicine. The patient, her parents, and the healthy controls signed informed consent.

**RESULTS**

**Case Report**

A 24 years old female patient, born from non-consanguineous healthy parents with normal development, had epilepsy for 11 years. The patient's two younger siblings were both unaffected (Figure 1B). According to the parents' recollection, high fever convulsions for 4–5 min occurred at 9 months and 2 years of age. At the age of 13, the patient first had an absence seizure accompanied by incontinence without obvious inducement. The absence seizure lasted a few minutes and occurred once or twice a month. In addition, generalized tonic-clonic seizures also occurred five times. After each seizure, the patient felt pain on the right side of the head. The patient was treated with valproate at age 20 (500 mg, three times daily). The frequency of absence seizures decreased but still occurred. At the age of 22, the dose of valproate was adjusted to two dose (1000 mg) twice daily. At the same time, the electroencephalogram (EEG) showed 8–9 Hz alpha waves companying with 5–7 Hz theta waves. Cranial magnetic resonance imaging (MRI) was normal (Figure 1A). 3 months later, due to the poor effect of valproate on epilepsy control, the patient was treated with levetiracetam twice a day reducing the dosage of valproate to 500 mg twice daily. After half a year, valproate was discontinued. The most recent follow-up was at age 24. The patient suffered from an absence of seizures twice in the past 2 years. An EEG showed 8–10 Hz alpha waves and 4–7 Hz slow waves.

**Genetic Findings**

The patient was revealed to have compound heterozygous variants in the LAMC3 (NG_029800.1, NM_006059, NP_006050.3) exon 2 c.470G > A/p.Trp157*, and exon 24 c.4030 + 1G > A by whole exome sequencing. Direct polymerase chain reaction and Sanger sequencing were used to verify these variants in the patient and her parents (Figure 1C). A heterozygous variant c.4030 + 1G > A on exon 24 of the father's LAMC3 gene, and a heterozygous variant c.470G > A on exon 2 of the mother's LAMC3 gene. c.470G > A was found in the Genome Mutation Database (HGMD). c.4030 + 1G > A was not found in the Genome Aggregation Database (gnomAD), 1000 Genome Project, or 1000 healthy controls. The pathogenicity prediction of the two variants was disease-causing for both using Mutation Taster (probability score: 1.0, range: 0–1.0 for both). In addition, c.470G > A was predicted to be damaging in PolyPhen2 and SIFT. Pathogenicity assessment according to the American College of Medical Genetics and Genomics (ACMG), revealed that both the c.470G > A and c.4030 + 1G > A were pathogenic (Richards et al., 2015).

**Functional Analysis**

A truncated protein with a molecular weight of 47 kDa was found in LAMC3 variant (c.470G > A) transfected cells, while a normal protein with a molecular weight of 198 kDa was found in the WT group (Figure 2A). However, the variant and WT group were both localized in the cytoplasm, and no significant difference was found (Figure 2B). To analyze of the variant c.4030 + 1G > A, three bioinformatics databases (BDGP, NetGene2, and HSF) were adopted to predict the effect of this variant on splicing, and all suggested that the variant would destroy the original Donor and affect the splicing. Then, the minigene comprising intron 23, exon 24, and intron 24 of the WT or variant (c.4030 + 1G > A) were constructed. Both the WT and mutated minigenes were transfected into HEK 293T and HeLa cells to verify this result, respectively (Figures 2C,D). The length of the product detected by RT-PCR in the WT group was consistent with the expected value in both HEK 293T and HeLa cells. However, a similar length of the product was observed in the variant group (Figure 2E). Furthermore, Sanger sequencing of RT-PCR products showed that the variant c.4030 + 1G > A affected the normal splicing of LAMC3 mRNA, resulting in 4 bp base (ATAC) retention at the left of intron 24 (Figure 2F). The retention of these 4 bp bases further resulted in the production of a truncated protein consisting of 1,367 amino acids.

**Prediction of the Pathogenic Mechanism**

Currently, the mechanism of OCCM caused by LAMC3 gene variants remained unclear. Therefore, this study intended to explore the pathogenic mechanism through bioinformatic methods. Firstly, online analysis software predicted that the first 19 amino acids of the laminin γ3 chain were the signal peptide sequences of the protein (Figure 3A), which was consistent with reported results (Koch et al., 1999). The STRING online database predicted ten genes (DAG1, LAMAI, LAM3, LAMA5, LAMB1, LAMB2, LAMB3, NID1, NID2, and NTN4) associated with LAMC3 at the interaction score of 0.4 (P value = 1.0e−16) (Figure 3B). The cellular component of gene ontology analysis indicated that LAMC3 and its interacting proteins were mainly located in the basement membrane, extracellular matrix organization, laminin complex (Figure 3C). In addition, the biological processes of these proteins were involved in extracellular matrix organization, cell adhesion, cellular component organization, and anatomical structure morphogenesis (Figure 3D). Furthermore, the molecular function of gene ontology analysis showed that these proteins were primarily associated with structural molecule activity, protein-containing complex binding, signaling receptor binding, and laminin-1 binding (Figure 3E). Finally, KEGG pathway enrichment showed that ECM-receptor interaction was the most significant pathway and the other pathways contained amoebiasis, small cell lung cancer, toxoplasmosis, focal adhesion,
human papillomavirus infection, PI3K-Akt signaling pathway, and pathways in cancer (Figure 3F).

**Literature Review**

In 2011, Barak et al. first identified LAMC3 gene variants as pathogenic variants in three unrelated Turkish families with occipital polymicrogyria and epileptic patients through whole-exome sequencing. Thus far, a total of 12 patients from six unrelated families worldwide (including our patients) have been reported with occipital cortical malformations due to LAMC3 variants. Genetic and clinical characteristics were summarized in Supplementary Table 1. Firstly, there were seven variants in the LAMC3 gene that have been identified, including one missense variant, five non-sense variants, and one frameshift variant. The patients in this study carried two variant sites in the LAMC3 gene: one was c.470G > A, which has been reported by Barak et al. (Barak et al., 2011), and the other was the frameshift variant (c.4030 + 1G > A). This was the first time this frameshift variant has been reported. Seizure was the most common clinical feature of patients with OCCM caused by LAMC3 gene variants. However, different patients suffered from different types of seizures, including myoclonic-astatic, atypical absence, complex partial, and vision loss. The patient in this study had an absence seizure as the main type of seizure, and had several generalized tonic-clonic seizures. The median age of seizure onset was 10 years old with a range of 2–13 years. In addition, developmental delay or degeneration was another typical clinical feature, including intellectual impairment, speech, fine motor skills delay, and language regression. However, the patient in this study had a normal developmental process with normal cognitive, language, and motor skills. Finally, pachygyria and polymicrogyria were the most representative imaging feature of patients with the LAMC3 gene variant. The occipital cortex was the most important accumulation site, and the frontal, temporal, and parietal cortex were also reported. Pachygyria and polymicrogyria were not observed in this patient.

**DISCUSSION**

OCCM was one kind of MCD characterized by polymicrogyria and pachygyria confined to the occipital lobe and childhood-onset seizures. Studies have found that complex heterozygous or homozygous variants of the LAMC3 gene were responsible for OCCM. This study reported a Chinese female patient with recurrent seizures due to a novel complex heterozygous variant of the LAMC3 gene. Among them, the non-sense variant (c.470G > A) has been reported by Barak et al. (Barak et al., 2011), while another the frameshift variant (c.4030 + 1G > A) was the first to be identified. Childhood-onset seizures, the most common clinical manifestation of OCCM, were also observed in this patient. However, what was remarkable about this patient was that cranial MRI did not show polymicrogyria and pachygyria in the occipital cortex or other areas. Furthermore,
FIGURE 2 | The functional analysis of complex heterozygous variants in LAMC3 gene. (A) The LAMC3 WT group expressed a normal protein with a molecular weight of 198 kDa and a truncated protein with a molecular weight of 47 kDa in LAMC3 variant group (c.470G > A). (B) The cellular localization of LAMC3 in WT and variant group was in the cytoplasm without significant morphological difference. (C) Sanger sequence of minigene in WT (above) and variant (below) group (c.4030 + 1G > A). (D) The schematic diagrams showed the minigene comprising intron 23, exon 24, and intron 24 of the WT or variant (c.4030 + 1G > A). The variant c.4030 + 1G > A affected the normal splicing of LAMC3 mRNA, resulting in 4 bp base (ATAC) retention at the left of intron 24, *** represents variant location. (E) Agarose gel electrophoresis of RT-PCR fragments showed a similar length of the product between the WT and variant group. (F) The Sanger sequences showed a 4 bp base (ATAC) retention at the left of intron 24 in the variant group.

the patient had no developmental delay, including language, motor, and cognitive ability. In terms of treatment, valproate could not control the occurrence of epilepsy in this patient, and levetiracetam achieved better control. This also provides a reference for the treatment of recurrent seizures caused by LAMC3 variant.

The laminins, major components of basement membranes, are heterotrimeric molecules composed of a combination of different α, β, and γ chains (Durbeej, 2010). Until now, five α chains (α1-α5), three β chains (β1-β3), and three γ chains (γ1-γ3) have been recognized to correspond to different gene products (Tunggal et al., 2000; Durbeej, 2010). The LAMC3 gene (NG_029800.1, NM_006059, NP_006050.3) contains a total of 28 exons, which encodes a laminin gamma-3 chain protein with 1575 amino acids. Thus far, one missense variant, five non-sense variants, and one frameshift variant of the LAMC3 gene have

FIGURE 3 | The bioinformatics analysis of LAMC3 gene. (A) The first 19 amino acids of the laminin γ3 chain were predicted as a signal peptide. (B) The protein-protein interaction network showed 10 genes (DAG1, LAMA1, LAMA3, LAMA5, LAMB1, LAMB2, LAMB3, NID1, NID2, and NTN4) that have potential interactions with LAMC3. (C) The cellular component of gene ontology showed LAMC3 and its interacting genes were mainly located in the basement membrane, extracellular matrix organization, laminin complex. (D) The biological process of gene ontology indicated these genes were mainly associated with extracellular matrix organization, cell adhesion, cellular component organization, and anatomical structure morphogenesis. (E) The molecular function of these genes were primarily involved in structural molecule activity, protein-containing complex binding, signaling receptor binding, and laminin-1 binding. (F) The KEGG pathway enrichment analysis showed eight potential signal pathways of these genes, including ECM-receptor interaction, amoebiasis, small cell lung cancer, toxoplasmosis, focal adhesion, human papillomavirus infection, PI3K-Akt signaling pathway, and pathways in cancer.
been identified including the two we found. More importantly, functional experiments demonstrated that both variant sites could cause premature truncation of the laminin γ3 chain. This is consistent with the previously reported effect of variants in the LAMC3 gene, suggesting the importance of the loss of function caused by premature truncation of laminin γ3 chain in OCCM.

To explore the pathogenic mechanism of the LAMC3 gene variant, we constructed a protein-protein interaction network with the LAMC3 gene using bioinformatics. The top ten genes (DAG1, LAMA1, LAMA3, LAMA5, LAMB1, LAMB2, LAMB3, NID1, NID2, and NTN4) were predicted to be associated with LAMC3. LAMA1, LAMA2, LAMC3, LAMB1, and LAMB2 genes can form different types of laminins through different permutations and combinations with LAMC3, such as laminin 213, 323, and 333 trimers (Li et al., 2012). In addition, LAMC3 was predicted to be related to NID1 and NID2, which was consistent with the previous study. The previous study demonstrated that the laminin γ3 chain was co-located with nidogen-1 and nidogen-2 (Iivanainen et al., 1999; Gersdorff et al., 2005). Furthermore, laminins are the major component of basement membranes, which together with the connective tissue matrix constituted the extracellular matrix (ECM) (Bonmans et al., 2014). The ECM has been shown to play role in structural support, cell differentiation, proliferation, adhesion, migration, and morphogens (Frantz et al., 2010; Hynes, 2014; Pozzi et al., 2017). Therefore, the laminin γ3 chain, as an integral part of the ECM, plays an important role in these functions. In addition, recent studies on the distribution and function of the laminin γ3 chain in the CNS have found that the laminin γ3 chain was also expressed in the cell body and apical dendrites of the pyramidal neurons on the human temporal occipital region from late fetal development to late infancy (Barak et al., 2011; Zambonin et al., 2018). In the KEGG pathway enrichment analysis, the ECM-receptor interaction was the most significant pathway, which was consistent with the distribution and function of the laminin γ3 chain. Furthermore, the PI3K-AKT signal pathway was predicted as a candidate effector pathway and was activated by growth factors including fibroblast growth factor 2 (FGF2) and insulin-like growth factor 2 (IGF2) to mediate the cell proliferation and growth in the developing brain (Hevner, 2015). However, whether the laminin γ3 chain was involved in the regulation of this pathway remains unclear. It should be noted that studies have shown that the PI3K/AKT pathway was critical in MCD (Ifliland and Crino, 2016; Benova and Jacques, 2019). For example, the mutation of the PI3K/AKT pathway was responsible for focal cortical dysplasias (FCDs), hemimegalencephaly (HMEG), and epileptogenic brain malformations (Jansen et al., 2015; Ifliland and Crino, 2017). Therefore, the PI3K-AKT signal pathway may be a key pathogenic pathway in OCCM caused induced by the LAMC3 gene variants. Animal model studies using LAMC3 gene knockout mice have shown only mild abnormalities. In the nervous system, ectopia of granule cells in the cerebellum, and increased branching of capillaries in the outer retina were observed (Li et al., 2012). In zebrafish embryos, LAMC3 knockdown resulted in defects in motor neuron guidance (Eve and Smith, 2017). Taken together, these studies suggest that LAMC3 plays a unique role in the nervous system.

CONCLUSION

This work identified novel compound heterozygous variants in the LAMC3 gene that causes OCCM with recurrent seizures without polymicrogyria and pachygyria. The administration of levetiracetam may be a relatively effective method to control epilepsy associated with LAMC3 variants. In addition, both variant sites in the LAMC3 gene could cause premature truncation of the laminin γ3 chain to loss of function. Finally, the extracellular matrix and the ECM-receptor interaction were the main location and signal transduction pathways of the laminin γ3 chain, respectively.
