A facile one-step hydrothermal approach to synthesize hierarchical core–shell NiFe$_2$O$_4$@NiFe$_2$O$_4$ nanosheet arrays on Ni foam with large specific capacitance for supercapacitors†

Xinyang Zhang, Ziqing Zhang, Shuanggan Sun, Yunpeng Wu, Qiushi Sun and Xiaoyang Liu

In this contribution, NiFe$_2$O$_4$@NiFe$_2$O$_4$ nanosheet arrays (NSAs) with three-dimensional (3D) hierarchical core–shell structures were synthesized by a facile one-step hydrothermal method and they were used as electrode materials for supercapacitors (SCs). The NiFe$_2$O$_4$@NiFe$_2$O$_4$ composite electrode showed a high specific capacitance of 1452.6 F g$^{-1}$ (5 mA cm$^{-2}$). It also exhibited a superior cycling stability (93% retention after 3000 cycles). Moreover, an asymmetric supercapacitor (ASC) was constructed utilizing NiFe$_2$O$_4$@NiFe$_2$O$_4$ NSAs and activated carbon (AC) as the positive and negative electrode, respectively. The optimized ASC shows extraordinary performances with a high energy density of 33.6 W h kg$^{-1}$ at a power density of 367.3 W kg$^{-1}$ and an excellent cycling stability of 95.3% capacitance retention over 3000 cycles. Therefore, NiFe$_2$O$_4$@NiFe$_2$O$_4$ NSAs have excellent pseudocapacitance properties and are good electrode materials for high energy density.

Introduction

With the continuous development of science and technology, the demand for electric energy is increasing. Therefore, higher electric energy storage is urgently needed. Tremendous efforts have been made to design and develop advanced energy storage devices. In recent years, supercapacitors (SCs) have been becoming promising and efficient energy storage devices due to their high power density, long cycling life and fast recharge capability. According to charging and storage mechanisms, SCs can be divided into two classes: electric double-layer capacitors (EDLCs) and pseudocapacitors. Pseudocapacitors which utilize the fast reversible redox faradaic reaction of the electrode materials can provide 2–3 times higher specific capacitance than EDLCs. In this respect, various high-performance electrode materials for pseudocapacitors, including conductive polymers, transition metal oxides, hydroxides, and sulfides, have been investigated in the past few years. As the most promising candidates, ternary transition metal oxides such as ZnFe$_2$O$_4$, CoFe$_2$O$_4$, NiFe$_2$O$_4$, CuFe$_2$O$_4$, NiO and Fe$_3$O$_4$, etc., have received considerable attention because of their low cost, natural abundance and environmental compatibility. In particular, ternary nickel ferrite (NiFe$_2$O$_4$) can be utilized as an electrode material for high performance SCs due to it exhibits better electrical conductivity and electrochemical performance than those of binary nickel oxide (NiO) and iron oxide (Fe$_3$O$_4$).

However, due to the low electrical conductivity and relatively small surface areas of transition metal oxides, the kinetics was limited in the redox reaction. To further improve the specific surface areas of these materials and achieve high specific capacitance, rational design of core–shell nanoarchitectures electrodes on conductive substrates as additive/binder-free electrodes became an attractive strategy. For instance, You et al. synthesized Co$_3$O$_4$/ZnFe$_2$O$_4$ hollow nanocomposite with a novel starfish-shaped structure by a simple hydrothermal method, of which a high specific capacitance of 326 F g$^{-1}$ at 1 A g$^{-1}$ was achieved and a good electrochemical cycling stability (80.7% retention after 1000 cycles) was showed. According to Zhang et al., the hierarchical NiCo$_2$O$_4$@MnMoO$_4$ core–shell nanoflowers were synthesized by the hydrothermal method, which showed a good electrochemical performance with specific capacitance of 1118 F g$^{-1}$ at 1 A g$^{-1}$, and extraordinary cycling stability (only 12.15% performance loss aerafter 5000 cycles). More recently, a three dimensional (3D) NiCo$_2$O$_4$@NiCo$_2$O$_4$ core–shell nanoflake arrays were synthesized by Tu et al. using a two-step hydrothermal method, which exhibited a high capacitance of 1.55 F.

† Electronic supplementary information (ESI) available. See DOI: 10.1039/c8ra02559b
cm$^{-2}$ at a current density of 2 mA cm$^{-2}$, and a high electrochemical performance retention rate of 98.6% over 4000 cycles.\textsuperscript{39}

To the best of our knowledge, the core–shell nanomaterials were traditionally fabricated via two steps, by “core” formation on a conductive substrate via electrodeposition or hydrothermal method, and a subsequent “shell” growth step on the surface of the “core”. In this work, we presented a facile one-step synthesis method to fabricate hierarchical NiFe$_2$O$_4$@NiFe$_2$O$_4$ core–shell NSAs on Ni foam as binder-free electrode. It was showed that the nanostructure of NiFe$_2$O$_4$@NiFe$_2$O$_4$ hierarchical core–shell nanosheets can be controlled by simply tuning the reaction time. As expected, the NiFe$_2$O$_4$@NiFe$_2$O$_4$ with the unique core–shell nanostructure manifested high faradaic capacitance as an additive/binder-free electrode for SCs. In addition, we had obtained the NiFe$_2$O$_4$@NiFe$_2$O$_4$ NSAs as the positive electrode and AC as the negative electrode. The optimized ASC exhibited a high energy density of 33.6 Wh kg$^{-1}$ at the power density of 367.3 W kg$^{-1}$, and outstanding cycling stability (95.3% of retention of initial electrochemical performance) after 3000 cycles, indicative of its great potential in high-performance SC applications.

**Experimental**

**Preparation of hierarchical NiFe$_2$O$_4$@NiFe$_2$O$_4$ core–shell NSAs on Ni foam**

Prior to the synthesis, Ni foam (length $\times$ width $\times$ thickness = 2 cm $\times$ 1 cm $\times$ 1.6 mm) were prepared and ultrasonicated cleaned using 3 M HCl solution, deionized water, acetone, and ethanol in sequence to eliminate the possible nickel oxide layer on the surface. NiFe$_2$O$_4$@NiFe$_2$O$_4$ NSAs were synthesized on Ni foam by a facile one-step hydrothermal process. 3 mmol of Ni(NO$_3$)$_2$·6H$_2$O, 2 mmol of Fe$_3$(SO$_4$)$_2$·7H$_2$O, 8 mmol of NH$_4$F and 12 mmol of CO(NH$_2$)$_2$ were dissolved in 100 mL deionized water. The solution was stirred at room temperature and a yellow solution was obtained. The solution was then transferred to a Teflon-lined stainless steel autoclave and the pretreated Ni foam was immersed into the solution. Subsequently, the autoclave was heated to 100 °C in an airflow electric oven for 2 h, 4 h and 6 h, respectively. After cooling down naturally, the Ni foam was taken out and rinsed with distilled water and alcohol, and it was annealed at 500 °C for 3 h (heating rate of 5 °C min$^{-1}$). Then the NiFe$_2$O$_4$@NiFe$_2$O$_4$ NSAs could be obtained on the Ni foam surface. The composites obtained with different reaction time of 2 h, 4 h and 6 h were denoted as NFNF-2, NFNF-4 and NFNF-6. Scheme 1 schematically illustrated the fabrication of the NiFe$_2$O$_4$@NiFe$_2$O$_4$ NSAs on the surface Ni foam surface via our proposed one-step hydrothermal method.

**Materials characterization**

The morphology of the NiFe$_2$O$_4$@NiFe$_2$O$_4$ NSAs was characterized by field-emission scanning electron microscopy (SEM, JEOL JSM 6700F) and transmission electron microscopy (TEM, FEI Tecnai G2 F20 S-Twin D573) with acceleration voltage of 200 kV. The energy dispersive X-ray spectroscopy (EDS) spectra were also acquired using a JEOL JSM 6700F microscope. The composition and structure of NiFe$_2$O$_4$@NiFe$_2$O$_4$ NSAs were examined by powder X-ray diffraction (XRD, Rigaku D/Max 2550V/PC, Japan Cu-K$_\alpha$ radiation, $\lambda$ = 0.15418 nm), and further confirmed by X-ray photoelectron spectroscopy (XPS, ESCALAB 250).

**Electrochemical characterization**

The electrochemical properties of as-prepared electrodes were measured on a CHI 760E electrochemical workstation using a three-electrode system in a 2 M KOH solution. Three-electrode system was consisted of a platinum counter electrode, a saturated calomel electrode (SCE) and the as-prepared hierarchical NiFe$_2$O$_4$@NiFe$_2$O$_4$ NSAs on Ni foam (1 cm $\times$ 1 cm), and they acted as the counter electrode, the reference electrode and the working electrode, respectively.

**Fabrication of NiFe$_2$O$_4$@NiFe$_2$O$_4$//AC ASC**

The ASC device was fabricated with NiFe$_2$O$_4$@NiFe$_2$O$_4$ NSAs as the positive electrode, AC as the negative electrode, and the 2 M KOH solution was used as the electrolyte. The specific capacitance, energy densities and power densities of the assembled ASC device were all calculated based on the total mass of both the NiFe$_2$O$_4$@NiFe$_2$O$_4$ and AC electrodes.

**Results and discussion**

Representative XRD and XPS patterns of the hierarchical NiFe$_2$O$_4$@NiFe$_2$O$_4$ NSAs were shown in Fig. 1. To eliminate the influence of the Ni foam, the composites were scratched from the Ni foam before measurement. The XRD patterns of NFNF-2, NFNF-4 and NFNF-6 were shown in Fig. 1a, all the peaks can be readily indexed to the monoclinic NiFe$_2$O$_4$ phase (JCPDS card no. 10-0325), indicating all the three samples were NiFe$_2$O$_4$.\textsuperscript{44} XPS was carried out to further investigate the surface information of the NiFe$_2$O$_4$@NiFe$_2$O$_4$ NSAs (Fig. 1b–d). As can be seen in
the survey scan of as-prepared hierarchical NiFe₂O₄@NiFe₂O₄ NSAs (Fig. 1b), the peaks of Ni, Fe and O were observed. Fig. 1c showed that the Ni 2p spectra. The peaks at 873.4 eV and 855.2 eV can be assigned to Ni 2p₁/₂ and Ni 2p₃/₂, respectively, which exhibited an separation of 18.2 eV consistent with the previously report.⁴⁶ The Fe 2p XPS pattern (Fig. 1d) showed two peaks at 725.4 and 711.8 eV, which could be assigned to the binding energy of Fe 2p₁/₂ and Fe 2p₃/₂, respectively, suggesting of the existence of Fe³⁺.

To explore the morphologies of the NiFe₂O₄@NiFe₂O₄ NSAs prepared with a different hydrothermal reaction time, the SEM was characterized and the images were collected and shown in Fig. 2. Within a short time (2 h), a number of the tiny NiFe₂O₄ nanoparticles appeared on the surface of the NiFe₂O₄ NSAs, acting as the ideal conductive scaffolds. After hydrothermal treatment for 4 h (Fig. 2b), the ultrathin NiFe₂O₄ nanoflakes were formed and uniformly covered on the surface of the NiFe₂O₄ nanosheets, developing a unique hierarchichal core–shell NiFe₂O₄@NiFe₂O₄ NSAs with approximately 1.9 µm wide and 210 nm thick. The hierarchical core–shell NSAs interconnected with each other, and thus a highly porous structure was formed resulting in a large specific surface area, which was beneficial for the electrolyte penetration and ion transportation.⁴⁷

When the reaction time extended to 6 h (Fig. 2c), the NiFe₂O₄ nanoflakes gradually occupied the free space between the “core” sheets and almost completely covered the surface of NiFe₂O₄ nanosheets. In order to obtain the uniform of the core–shell structure of NiFe₂O₄@NiFe₂O₄ NSAs on Ni foam, the low magnification SEM was measured and the images were shown in Fig. S1.*

The corresponding TEM images in Fig. 3a–c also revealed the growth process of the NiFe₂O₄@NiFe₂O₄ NSAs. As shown in Fig. 3b, the NiFe₂O₄ core nanosheets were composed of NiFe₂O₄ nanoflakes of 37 nm in length. Moreover, the representative HRTEM image in Fig. 3d showed that the NNFN-4 NSAs had a set of lattice fringes with interplanar distance of 0.26 nm, well corresponding to the (311) plane of cubic spinel NiFe₂O₄ (JCPDS card no. 10-0325). To further verify the elemental distribution in the electrode material, the EDS mapping image was obtained and shown in Fig. 3e–h. The results indicated that the Ni, Fe, O elements were uniformly distributed throughout the core–shell nanostructure. Furthermore, the EDS pattern also confirmed the presence of Ni and Fe with an atomic ratio of about 1 : 2 (Fig. S2†).

**Electrochemical performance of NiFe₂O₄@NiFe₂O₄ NSAs**

Electrochemical characterizations of NNFN-2, NNFN-4 and NNFN-6 as electrode materials for SCs were carried out by using the three-electrode system in 2 M KOH aqueous solutions (Fig. 4). The cyclic voltammetry (CV) comparison curves of NNFN-2, NNFN-4 and NNFN-6 at the same scanning rate (5 mV s⁻¹) and in the same potential window (−0.2 to 0.8 V) were shown in Fig. 4a. As shown in Fig. 4a, each of the CV curves had a pair of obvious redox peaks, suggesting of the presence of a faradaic reaction. During the charge–discharge process of electrode materials, the mechanism of redox reaction can be represented as the following reaction:⁴⁷

\[
\text{NiFe}_2\text{O}_4 + \text{H}_2\text{O} + \text{OH}^- \leftrightarrow \text{NiOOH} + 2\text{FeOOH} + e^-
\]

Furthermore, the CV-integral area of the NNFN-4 electrode was higher than those of NNFN-2, NNFN-6 electrodes,
demonstrating a significant increase of the areal capacitance. This fact could also be further evidenced by the CD measurements at the same current density (10 mA cm\(^{-2}\)) in Fig. 4b. Evidently, the CD curves of NFNF-2, NFNF-4 and NFNF-6 showed a good symmetry, indicating an excellent reversibility. Besides, the CD curve of the NFNF-4 electrode had the longest discharging time, exhibiting the most extraordinary pseudocapacity among the three electrodes, which was consistent with the above CV analysis.

Fig. 4c showed the CV curves of the NFNF-4 NSAs electrode for supercapacitor with a same potential range of −0.2 to 0.8 V at various scan rates from 5 to 60 mV s\(^{-1}\). Specifically, a pair of similar redox peaks was observed in all the CV curves, implying that a high-rate faradaic redox reaction happened on the electrode. The NFNF-4 NSAs displayed a pair of redox peaks at 0.520 V and 0.275 V at a slow scan rate of 5 mV s\(^{-1}\). As the scan rate gradually increased, the peak current increased and shape of the CV curves were slightly change, indicating that electrode materials could provide or accept electrons through redox reactions.\(^{48}\) The electrochemical characterizations of the NFNF-4 NSAs was further confirmed by CD measurements at current densities of 5, 10, 20, 40 and 60 mA cm\(^{-2}\) (Fig. 4d). For comparison, the detailed CV and CD measures of the NFNF-2 and NFNF-6 composite electrodes were shown in Fig. S3.\(^{\dagger}\)

The mass specific capacitance and areal specific capacitance of the NFNF-2, NFNF-4, and NFNF-6 NSAs electrodes were calculated from the discharge time by the following equations:

\[
C_m = \frac{I \times \Delta t}{m \times \Delta V}
\]

\[
C_a = \frac{I \times \Delta t}{S \times \Delta V}
\]

where \(C_m\) and \(C_a\) were the mass specific capacitance and the areal specific capacitance, respectively. \(I\) was the discharge current, \(\Delta t\) was the discharge time, \(m\) was the total mass of the active material in the electrode, \(\Delta V\) was the voltage interval and \(S\) was the geometrical area of the electrode. The corresponding results of these electrodes were presented in Fig. 4e–f. Impressively, the NFNF-4 electrode possessed high mass specific capacitances of 1451.5, 1377.4, 1274.5, 1164.7 and 923.6 F g\(^{-1}\), respectively.
and high areal specific capacitances of 1.74, 1.65, 1.53, 1.40 and 1.11 F cm\(^{-2}\) at current densities of 5, 10, 20, 40, and 60 mA cm\(^{-2}\), respectively. Nevertheless, the NFNF-2 and NFNF-6 electrodes only showed 1.13 F cm\(^{-2}\) (1031.6 F g\(^{-1}\)) and 1.55 F cm\(^{-2}\) (1193.1 F g\(^{-1}\)) at 10 mA cm\(^{-2}\). In addition, the detailed comparison results of NFNF-2, NFNF-4 and NFNF-6 electrodes were summarized in the Table S1.\(^\dagger\) The results were much better than previously reported values of NiFe\(_2\)O\(_4\) nanostructures, such as CoFe\(_2\)O\(_4\)/NiFe\(_2\)O\(_4\) nanocomposites (269 F g\(^{-1}\)) and NiFe\(_2\)O\(_4\)/PANI nanocomposites (448 F g\(^{-1}\)) from the three-dimensional core–shell structure. Fig. S4 and inset shows the CD curves of the last 10 cycles.

The cycling performance of the NFNF-2, NFNF-4, and NFNF-6 NSAs were also investigated to further evaluate the potential to serve as electrode materials for SCs. As depicted in Fig. 5, cycling stability tests for the NFNF-2, NFNF-4 and NFNF-6 NSAs were performed by measuring the retention rates of their initial capacitances over 5000 cycles at a current density of 10 mA cm\(^{-2}\). After 5000 cycles, the specific capacitance retention rates of the three electrodes were all above 79.6%. The specific capacitance retention rate of the NFNF-4 electrode (1241.2 F g\(^{-1}\), 90.2% retention) was the highest among the three electrodes, demonstrating the superior electrochemical stability originated from the three-dimensional core–shell structure. Fig. S5 and S6\(^\dagger\) showed the SEM and Nyquist plots of NiFe\(_2\)O\(_4@NiFe\(_2\)O\(_4\) core–shell NSAs after 5000 cycling tests. We can observe that the morphology of the core–shell nanosheet arrays retained almost intact, which further demonstrated its high stability.

Electrochemical performance of the NiFe\(_2\)O\(_4@NiFe\(_2\)O\(_4\)//AC ASC

An ASC was assembled utilizing NiFe\(_2\)O\(_4@NiFe\(_2\)O\(_4\) NSAs as the positive electrode and AC as the negative electrode in 2 M KOH electrolyte, to further confirm the extraordinary electrochemical performance that could be potentially applied in practical applications (Fig. 6a). Fig. 6b showed the CV curves of NFNF-4 and AC electrodes using a three-electrode system at a scan rate of 5 mV s\(^{-1}\). It can be seen that NFNF-4 was measured within a potential window of 0 to 0.8 V, and AC electrode within a potential window of −1.0 to 0 V. The CV curve of AC electrode exhibited a nearly ideal rectangular shape without any redox peaks, demonstrating a typical characteristic of EDLC behavior.\(^\dagger\) Based on these results, the total potential window of the assembled ASC could be extended to 0–1.8 V. From the CV curves of the ASC device (Fig. 6c) recorded at different scan rates of 5–60 mV s\(^{-1}\), it was found that the overall capacitance of the NiFe\(_2\)O\(_4@NiFe\(_2\)O\(_4\)//AC ASC device was a result from the combination of both faradaic pseudocapacitance and EDLC-type capacitance. Fig. 6d showed the CD curves of the ASC device at current densities of 2–40 mA cm\(^{-2}\) with the potential range from 2 to 3.6 V. The ASC device exhibited a nearly ideal rectangular shape without any redox peaks, demonstrating a typical characteristic of EDLC behavior.
window of 0–1.8 V. Ragone plot relative to the corresponding energy density \(E\) and power density \(P\) were calculated as follows:

\[
E = C \times \Delta V^2 / 7.2
\]

(3)

\[
P = 3600 \times E / \Delta t
\]

(4)

where \(E\), \(P\), \(C\), \(\Delta V\) and \(\Delta t\) were energy density, power density, specific capacitance, cell voltage, \(\text{s}\) and discharging time, respectively. (Fig. 6e). The maximum energy density \((33.6 \, \text{W h kg}^{-1})\) was achieved at a power density of \(367.3 \, \text{W kg}^{-1}\), and maintained at \(16.6 \, \text{W h kg}^{-1}\) with a high power density of \(734.6 \, \text{W kg}^{-1}\). The energy density of \(\text{NiFe}_2\text{O}_4@\text{NiFe}_2\text{O}_4/\text{AC}\) ASC device was higher than the previous reported ASC, for results proved that the \(\text{NiFe}_2\text{O}_4@\text{NiFe}_2\text{O}_4/\text{AC}\) ASC device had possessed an extraordinary cycling stability. All these attractive values a capacitance of the ASC maintained above 95.3% of the initial \(t\), also indicating that the ASC device demonstrating its superior cycling stability. Moreover, the inset and AC, which exhibited a high energy density of \(33.6 \, \text{W h kg}^{-1}\). This journal is © The Royal Society of Chemistry 2018 RSC Adv., 2018, 8, 15222–15228 | 15227

\[
